KEY TO PRONUNCIATION

For a full explanation of the various sounds indicated, see the Key to Pronunciation in Vol. I.

ā	as in ale, fate.
ā̇	" " senate, chaotic.
â	" " glare, care, and as *e* in there.
ă	" " am, at.
ä	" " arm, father.
ȧ	" " ant, and final *a* in America, armada, etc.
a	" " final, regal, pleasant.
a̤	" " all, fall.
ē	" " eve.
ē̇	" " elate, evade.
ĕ	" " end, pet.
ẽ	" " fern, her, and as *i* in sir, etc.
e	" " agency, judgment.
ī	" " ice, quiet.
ī̇	" " quiescent.
ĭ	" " ill, fit.
ō	" " old, sober.
ō̇	" " obey, sobriety.
ô	" " orb, nor.
ŏ	" " odd, forest, not.
o	" " atom, carol.
oi	" " oil, boil.
o͞o	" " food, fool, and as *u* in rude, rule.
ou	" " house, mouse.
ū	" " use, mule.
ū̇	" " unite.
ŭ	" " cut, but.
ụ	" " full, put, or as *oo* in foot, book
û	" " urn, burn.
y	" " yet, yield.
B	" " Spanish Habana, Córdoba, where it is like English *v* but made with the lips alone.

ch	as in chair, cheese.
D	" " Spanish Almodovar, pulgada, where it is nearly like *th* in English then.
g	" " go, get.
G	" " German Landtag = *ch* in Ger. ach, etc.
H	" *j* in Spanish Jijona, *g* in Spanish gila; like English *h* in hue, but stronger.
hw	" *wh* in which.
K	" *ch* in German ich, Albrecht = *g* in German Arensberg, Mecklenburg, etc.
n̠	" in sinker, longer.
ng	" " sing, long.
N	" " French bon, Bourbon, and *m* in the French Étampes; here it indicates nasalizing of the preceding vowel.
sh	" " shine, shut.
th	" " thrust, thin.
TH	" " then, this.
zh	" *z* in azure, and *s* in pleasure.

An apostrophe ['] is sometimes used as in tā'b'l (table), kăz''m (chasm), to indicate the elision of a vowel or its reduction to a mere murmur.

For foreign sounds, the nearest English equivalent is generally used. In any case where a special symbol, as G, H, K, N, is used, those unfamiliar with the foreign sound indicated may substitute the English sound ordinarily indicated by the letter. For a full description of all such sounds, see the article on Pronunciation.

A PARTIAL LIST OF THE LEADING ARTICLES IN VOLUME XIV

LEPROSY.
Dr. Albert Warren Ferris.
Dr. David Gilbert Yates.
LESSING.
Dr. Benjamin Willis Wells.
Professor Lawrence McLouth.
LETTERS IN LITERATURE.
Dr. Horatio S. Krans.
LETTIC LANGUAGE AND LITERATURE.
Mr. Felix Vexler.
LEVELING.
Mr. Herbert Treadwell Wade.
LEVITICUS.
Professor Morris Jastrow.
Professor Nathaniel Schmidt.
LIBERIA.
Professor Robert M. Brown; Mr. Edward Lathrop Engle; Major LeRoy S. Lyon, U. S. A.; Professor J. Salwyn Schapiro; Mr. Irwin Scofield Guernsey.
LIBERTY, RELIGIOUS.
Professor Alvin Saunders Johnson.
LIBERTY OF THE PRESS.
Professor George W. Kirchwey.
LIBRARIES.
Professor James Morton Paton; Mr. Charles Alexander Nelson; Dr. Melvil Dewey; Dr. James Hulme Canfield; Mr. William Warren Bishop.
LIEBIG.
Professor Martin A. Rosanoff.
LIÈGE.
Mr. Edward Lathrop Engle.
LIEN.
Professor George W. Kirchwey.
LIFEBOAT.

* Deceased.

THE NEW
INTERNATIONAL
ENCYCLOPÆDIA

LEP′ROSY (OF. *leprosie*, from ML. *leprosia*, from MGk. *λέπρωσις*, *leprōsis*, leprosy, from Gk. *λεπροῦσθαι*, *leprousthai*, to become leprous, from λέπρα, *lepra*, leprosy). A constitutional disease of chronic character, endemic in certain localities, contagious through intercourse with an infected person, and due to the presence of the *Bacillus lepræ* (Hansen); being characterized by the formation of nodular infiltrations and other nutritional changes in the skin and by an eruption. It is also called *Lepra*, *Elephantiasis Græcorum*, *Satyriasis*, *Leontiasis*, as well as *Zaraath*, or *Tsaraath*, in Hebrew, and *Uchetie* in Egyptian. It is known in China as *Fa-Fung*, in India as *Kushta*, in Arabia as *Juzam Dolfil*, and in Norway as *Spedalskhed*. Egypt is called the cradle of leprosy, and it certainly existed in that country from a very remote period. On papyri found in the tombs of kings descriptions of it are given. The Papyrus Ebers, transcribed in the fifteenth century B.C., describes and prescribes for it. Assyrian and Babylonian hieroglyphics relate to the disease. It has existed in India at least 3000 years. Leprosy was described by a writer of 2000 years ago in China. Greece had seen the disease before Hippocrates wrote of it. It was probably taken to Arabia before the time of Mohammed. It was common among the Jews in 260 B.C. Aretæus (81 A.D.) found it spreading over western Europe. The Romans contracted it from the Greeks; the troops of Pompey carried it into Italy in the first century B.C. Pilgrims from the Holy Land introduced the disease into England (Simpson). The returning Crusaders in the tenth, eleventh, and twelfth centuries spread the disease thoroughly. Wales, Ireland, Norway, Sweden, and other parts of Europe became infected. The invasion of America by the disease cannot be traced.

Segregation of lepers was practiced at a very early date. According to Herodotus, the Persians exiled lepers in his day. Moses, following Egyptian customs, segregated lepers among the Jews. Canthie is authority for the statement that the Chinese burned lepers alive. In the Middle Ages leprosaria were established in France under chaplains, and the lepers were uniformly garbed and provided with a rattle, with which to warn others of their approach. In the time of Louis VIII there were 2000 leper houses in France, while the number in Europe, excluding those in Russia and Sweden, was 19,000 (Morrow). In the British Isles isolation was enforced, lodgings in leper houses, cowls, gray habits, sticks, and clappers being furnished to the unfortunates. In modern times strict segregation is practiced in almost all localities where lepers are found. In the United States Louisiana, California, and Massachusetts have established special hospitals for lepers. In various other States isolation pavilions or other means of segregation are provided as necessity arises. It is estimated that there are in the world nearly 3,000,000 lepers, China furnishing 2,000,000 of these and India furnishing 200,000. Japan has 20,000 known lepers, and Africa, Arabia, Persia, Russia, Norway, Sweden, Italy, Greece, and Spain have most of the remainder. There are many cases in Central and South America, Mexico, and the West Indies, and a few in Canada.

The annexation of the Hawaiian Islands (q.v.) by the United States carried with it the problem of caring for the lepers. In 1898 Dr. D. A. Carmichael, of the United States Marine Hospital Service, made an extended report on leprosy in the Hawaiian Islands. There were then in the leper settlement on Molokai 1073 lepers; also 61 nonleprous children of leprous parents; also 73 helpers (Kokuas), nonleprous persons living in the settlement and caring for relatives; also nonleprous priests, sisters, brothers, teachers, etc., 61. Grand total, 1207. The new cases in 1900 were but 85 in number, as compared with 132 in 1890. At the close of 1901 the number had fallen to 909, and as a result of rigorous regulation the number has tended to constantly decrease. According to a survey made by the United States Public Health Service, there were, in 1911, 278 lepers in the United States proper, only 72 of which were isolated and cared for by the local authorities. There were in addition 28 known lepers in Porto Rico, the leper colony of which is on Cabras Island. In the Philippine Islands the disease constitutes an important health problem. About 6000 lepers had been transferred to the Culion leper colony; Cebu, an island with one-tenth of the Philippine population, furnishing one-half of the cases.

Leprosy spreads by contagion. It is believed that the organism obtains entrance through the nasopharynx and is spread by the nasal secretions. In practically all cases ulcerations in this situation are found. For many years, owing to the vigorous advocacy of the theory by Jonathan Hutchinson, a fish diet was believed to be responsible for leprosy. Hutchinson based his contention chiefly on conditions in India. Other observers, however, point out the fact that the disease is widespread among those castes whose religious beliefs forbid the eating of fish. Goodhue, in the Hawaiian Islands, found the *Bacillus lepræ* in mosquitoes and bedbugs. The bacillus of leprosy was discovered by Hansen (q.v.), of Bergen, Norway, in 1871. Neisser, in 1879, after extended researches, confirmed Hansen's claims. The bacillus is a straight or slightly curved thin rod, nonmotile, occurring singly or in pairs attached end to end, but not in chains. When stained, it appears like the bacillus of tuberculosis, but often takes stain in such a way as to suggest that the protoplasm is fragmented, the bacilli then appearing like cocci in short rows, darkly stained points alternating with unstained points. The bacilli appear in very large numbers in the leprous tissue, especially in the tubercular form, lying in bundles of several bacilli arranged parallel to each other, the bundles lying in various directions. Under the influence of the bacillus nodules of new tissue are formed in the skin or subcutaneous tissue. These nodules resemble granulation tissue, being made up of a fibrous stroma, in which are cells of various shapes. Bacilli are present in the tissue in large numbers, both in and between the cells. The nodules are most common in the exposed parts of the skin, face, hands, etc., but may occur in any part of the skin. The mucous membrane of the eyes, nose, and mouth may be affected. More rarely nodules develop in deeper parts of the body. The nodules may be large or small. There may be extensive ulceration with later cicatrization, sometimes producing in the face the so-called "facies leontina." Deep ulcers affecting the fingers or toes may result in extensive loss of substance—"lepra mutilans." In the form known as anæsthetic leprosy the lesion seems to be a peripheral neuritis, due to the presence of the bacilli in the nerves.

Among the most notable symptoms of leprosy are fever of an irregular type, malaise, dyspepsia, nosebleed, vertigo, headache, neuralgia, pains in the arms and legs, and excessive action of the oil and sweat glands. Nearly all victims have a sense of depression and a feeling of impending calamity.

Some authorities mention three forms of leprosy: the *macular*, characterized by dark-red or black stains; the *anæsthetic*, characterized by loss of sensation in patches of the integument and flesh; and the *tubercular*, characterized by nodules of tubercular granulation tissue, or a diffuse infiltration in skin and mucous tissue. Some cases unite all three varieties. In the macular-anæsthetic type the chief changes are in the nerves, leading to destruction of nerve fibres with consequent anæsthesia, paralysis of muscles, and trophic disturbances. The period of incubation of leprosy is from three to seven or more years, patches first appearing on the unexposed parts of the body, with ulcers on the upper part of the nasal passages, thus rendering detection difficult. Heredity in leprosy is not considered a factor.

There is no specific treatment for this disease, but of an innumerable list of remedies which have been used since the time of Moses a few appear to give satisfactory results. One of the oldest is chaulmoogra oil. More cures have resulted from its use than from any other single remedy. In India it is extensively employed. In the Fiji Islands the patient is placed on a pyre of green leaves of a tree supposed to be specific against leprosy. The skin is slowly cooked and scorched, and if the victim survives the treatment he may recover. In the West Indies and some parts of South America it is believed that the bite of a venomous snake will cure, and acting on this theory Dyer used the antivenomous serum of Calmette with uniformly good effect. Of a number of specific serums which have been prepared, leprolin, introduced by Root, of the Indian Medical Service, has proved moderately successful. It is derived from a toxin of the *bacillus lepræ*. Where there are superficial ulcerations the X ray tends to promote healing. Consult: Sir Jonathan Hutchinson, *On Leprosy and Fish Eating* (London, 1906); Hawaii Board of Health, *The Molokai Settlement* (Hawaii, 1907); W. R. Brinckerhoff, "The Present Status of the Leper Problem in Hawaii," in *Public Health Bulletin, No. 184* (Washington, 1908); Rupert Blue, *The Public Health Aspects of Leprosy in the United States* (Chicago, 1913); McCoy and others, "Studies upon Leprosy," in *Public Health Bulletin, No. 61* (Washington, 1913). See HANSEN.

LEPSIUS, lĕp′sē-ụs, KARL RICHARD (1810–84). A German archæologist and Egyptologist, born at Naumburg, Dec. 23, 1810. He studied at Leipzig, Göttingen, Berlin, and Paris. His first work, *Die Paläographie als Mittel der Sprachforschung* (1834), received the Volney prize of the French Institute. For some years after this he wrote chiefly on paleography, on the Etruscan, Oscan, and Umbrian inscriptions (*Inscriptiones Umbricæ et Oscæ*, 1841), and on comparative philology (*Zwei sprachvergleichende Abhandlungen*, 1836, etc.). With his *Lettre à M. le professeur H. Rosellini sur l'alphabet hiéroglyphique* (1837), written while he was living at Rome (where he became intimately acquainted with Bunsen), he entered the field of hieroglyphic research. In 1842 he was placed at the head of an expedition sent to Egypt by the King of Prussia and spent three years (1842–45) in exploring the ruins of Egypt and Nubia as far as Khartum. The results of this expedition were given to the world in the magnificent work *Denkmäler aus Aegypten und Aethiopien* (1850–59), published at the expense of the King, and in his *Briefe aus Aegypten* (1852). In 1866 he again visited the place and discovered the Canopus Tablet, which, like the Rosetta stone, had its inscriptions in hieroglyphic, demotic, and Greek. He became professor of Egyptology at Berlin in 1846, director of the Berlin Egyptian Museum in 1865, and director of the Royal Library in 1873. Of his numerous works the following are the most important: *Chronologie der Aegypter* (1840); *Todtenbuch der Aegypter* (1842); *Das bilingue Decret von Kanopus* (1866). He also wrote on metrology, *Die Längenmasse der Alten* (1884), and on phonetics, *Standard Alphabet for Reducing Unwritten Languages, etc.* (1863). His *Nubische Grammatik* (1880) touched on comparative African philology. He died July 10, 1884. Consult Georg Ebers, *Richard Lepsius, ein Lebensbild* (Leipzig, 1885; Eng. trans., New York, 1887).

LEPTÆ′NA (Neo-Lat., from Gk. λεπτός, *leptos*, slender). A fossil brachiopod genus characteristic of the Middle Paleozoic rocks throughout the world. The shells are of deltoid outline, with concentric folds and fine radiating lines.

All the varieties, ranging from the Upper Ordovician into the Lower Carboniferous rocks, are probably only modifications of a single race typified by the species *Leptæna rhomboidalis*, which has undergone adaptive changes caused by the climatic and physical conditions during the various geological epochs in which it lived.

LEPTAN′DRA (Neo-Lat., from Gk. λεπτός, *leptos*, slender + ἀνήρ, *anēr*, male; in modern botanical terminology, stamen). A generic name proposed by Nuttall for *Veronica virginica*, Culver's root, or Culver's physic, and now employed as the pharmaceutical name of that plant. In America it grows in rich woods from Vermont and Manitoba southward and is often cultivated for ornament. It blossoms in July and August. See Speedwell, and Plate of Bloodroot, etc., accompanying article Sanguinaria.

LEPTOCARDII, lĕp′tȯ-kär′dĭ-ī (Neo-Lat. nom. pl., from Gk. λεπτός, *leptos*, slender + καρδία, *kardia*, heart). A class of small fishlike animals belonging to the phylum Chordata. It includes two genera, *Amphioxus* and *Asymmetron*. The leptocardians are commonly classed with the vertebrates, although they possess no true backbone, and as such they form the Acrania in distinction to all the remaining vertebrates—the Craniata. (See Classification of Animals.) Because of this primitive organization and consequent low position among chordates, they form a most important group for the naturalist, and their anatomy and development have been extensively studied. See Amphioxus.

LEPTODIS′CUS. See Noctiluca.

LEP′TOME (from Gk. λεπτός, *leptos*, slender). The conducting portion of the phloëm of a vascular bundle. It includes the sieve tubes, companion cells, and bast parenchyma, but not the bast fibres. See Hadrome, Mestome.

LEP′TOMEN′INGI′TIS. See Meningitis.

LEP′TOSPORAN′GIATES. A name applied to those vascular plants whose sporangia arise as external organs from a single superficial cell. The contrasting plants are eusporangiates, whose sporangia are developed beneath the epidermis, although of course they usually project above the surface. The leptosporangiate condition is exceptional, since it occurs only in the majority of modern ferns. Some of the ferns, all of the rest of the Pteridophytes, and all the seed plants are eusporangiate.

LE PUY, l*e* pwē. A town of France. See Puy, Le.

LE QUEUX, l*e* kū, William Tufnell (1864–). An English novelist, born in London. He was educated there and in Italy, was an art student, then a journalist in Paris, and on his return to London was editor of *Gossip* and *Piccadilly*, and from 1888 to 1893 parliamentary reporter and then subeditor on the *Globe*. He traveled much, in the East, in Africa, and in the Arctic, and became a member of the Council of the Republic of San Marino. His novels include: *Guilty Bonds* (1890); *Devil's Dice* (1896); *Of Royal Blood* (1899); *In White Raiment* (1900); *Her Majesty's Minister* (1901); *The Tickencote Treasure* (1902); *Secrets of the Foreign Office* (1903); *The Invasion* (1906); *The House of Whispers* (1909); *Hushed Up* (1910); *Fatal Fingers* (1912); *The Death-Doctor* (1912); *The Hand of Allah* (1914); *The War of the Nations* (1914); *Whoso Findeth a Wife* (1915).

LERAY, le-rå′, Francis Xavier (1825–87). An American Catholic prelate. He was born at Châteaugiron, France; was educated at Rennes; and, having come to the United States at 18 and studied theology in the Sulpitian College, Baltimore, was ordained a Roman Catholic priest in 1852. He taught in St. Mary's College, Maryland, and became its prefect. After missionary labors in the West, he worked at Jackson, Miss., during the epidemic of 1853, and at Vicksburg, Miss., in 1857–61. After the Civil War, in which he served as a Confederate chaplain, he returned to Vicksburg, rendered valuable service during the plague of 1867, and in 1873 was made Bishop of Natchitoches, La. He was appointed Archbishop of New Orleans in 1883, and died in France.

LERCHE, lĕr′k*e*, Vincent Stoltenberg (1837–92). A Norwegian genre and architectural painter, born at Tönsberg. He was a pupil of Gude at the Düsseldorf Academy. In 1863 he won a traveling prize that enabled him to visit Italy, where he devoted himself chiefly to architectural drawing. He afterward visited the Rhinelands and Scandinavia. His best works are interiors of churches or convents, later used as backgrounds for genre scenes of monastic life in the Middle Ages, portrayed with humor and charm. Among the best of these are "The Interior of St. Lambertus in Düsseldorf" (1862, Bergen Museum); "Cardinal" (1870, Christiania Museum); "The Cloister Library" (1872, Stockholm Museum); "Collection Day at the Dominican Monastery" (1873, Christiania Gallery). He was also a wood engraver, caricaturist, and author.

LERCHENFELD, Amand, Baron von Schweiger-. See Schweiger-Lerchenfeld, Amand, Baron von.

LERDO DE TEJADA, lår′dȯ då tå-hä′då, Miguel (1812–61). A Mexican statesman, born in Vera Cruz. In 1852 he was president of the city council of Mexico and in 1855 was appointed Secretary of the Treasury in the administration of President Comonfort. In order to diminish the importance of the clergy and public corporations, he framed, while in this office, the Ley Lerdo (1856), which removed from all civil and ecclesiastical corporations the right to hold lands beyond that necessary for their legitimate operation, and provided that all unoccupied church lands should be sold at an assessed valuation. This radical measure, aimed at the Conservative or reactionary party, caused his retirement in 1857. In 1859, after the accession of Juárez to the presidency, Lerdo again became Secretary of the Treasury. Continuing his attack on the reactionaries, he aided in carrying through a law for nationalizing the landed property of the church and placing the religious orders under government inspection and control. In 1860 he became a judge of the Supreme Court. His friends made an unsuccessful attempt to elect him to the presidency.

LERDO DE TEJADA, Sebastian (1825–89). President of Mexico. He was born at Jalapa in the Province of Vera Cruz, was educated in the Seminary of Puebla and afterward studied law in the city of Mexico. He was admitted to the bar in 1851, became a judge of the Supreme Court in 1855, and two years later was made Minister of Foreign Affairs. Elected to Congress in 1861, he was chosen president of that body. In 1863 he was the first Minister of Justice, and then Minister of Foreign Affairs, always allied with the Liberal party. He was one of the most prominent leaders in opposition to the French intervention in Mexico, served the Provisional Government of Juárez faithfully while he was a fugitive and exile, and preserved a consistent attitude of antagonism to the Emperor Maximilian, whose death may be charged justly to Lerdo de Tejada and Juárez. On the return of the Republican government to the capital in 1867, after the withdrawal of the French, Juárez was reëlected President, and Lerdo became Chief Justice of the Supreme Court with a seat in the cabinet, and on the death of Juárez, in 1872, he succeeded him as President by virtue of his office. In October of that year he was elected President for four years. His administration was marked by considerable progress in economic and constitutional development, and the country enjoyed a comparatively long period of peace. In 1875, however, the elements opposed to a strong central government made common cause with the clerical reactionists, and a revolution broke out in several Mexican states simultaneously. In the presidential election of 1876 Lerdo was a candidate for reëlection and was opposed by Gen. Porfirio Díaz; Lerdo was declared successful, but his opponents asserted that official influence had been brought to bear on the voters and that the election was fraudulent. Díaz at the head of an army marched against the capital, and on Nov. 20, 1876, President Lerdo escaped to Acapulco. He went to the United States early in 1877, and subsequently resided in New York, where he died.

LERICI, lā'rē-chē. A city in the Province of Genoa, Italy, 4 miles southwest of Sarzana, which is 65 miles by rail southeast of Genoa (Map: Italy, B 2). It has a small harbor on the Gulf of Spezia and an ancient castle. In the Middle Ages it was the principal city on the gulf. It has machine works, iron foundries, shipyards, and fisheries. Pop. (commune), 1901, 9026; 1911, 9290.

LÉRIDA, lā'rē-ᴅȧ. The capital of the Spanish province of the same name, situated on the river Segre, a tributary of the Ebro, about 80 miles west by north of Barcelona, and on the railroad between that city and Saragossa (Map: Spain, F 2). It is built partly on a plain and partly on an eminence on the top of which stands an ancient castle. The town, which is important from a military point of view, is surrounded by walls and a moat and commanded by the citadel. It is a gloomy labyrinth of narrow and crooked streets, but contains a number of interesting old buildings, the most prominent being an old cathedral built in the thirteenth century in a strange mixture of Byzantine, Gothic, and Moorish architecture and now used as barracks; the church of San Juan, an interesting Byzantine monument of the twelfth century; several old convents, and a palace of the kings of Aragon. The town has a bishop's palace, a new cathedral in Corinthian style, a normal school, a theological seminary, and several academies, literary and scientific societies. Lérida has manufactures of wool, cotton, silk, leather, and glass. Pop., 1887, 21,885; 1900, 21,352; 1910, 24,531. Lérida is the Celtiberian Ilerda, noted for its heroic resistance to the Romans. It became an episcopal see under the Visigoths, and a council was held there in 546.

LÉRINS, lā'räɴ', Îles de. A group of small islands in the Mediterranean, off the south coast of France, and less than 2 miles from the mainland, forming a part of the Department of Alpes-Maritimes. It consists of the two small islands of Sainte-Marguerite (four miles in circumference) and Saint-Honorat (two miles in circumference) and a number of islets. They were settled at a very early period and played a prominent part in the monastic life of France. Sainte-Marguerite has a fort, in which were imprisoned the Man in the Iron Mask and Marshal Bazaine. Saint-Honorat has the ruins of an old monastery believed to have been founded by Saint-Honorat in the fourth century, and now inhabited only by a few monks. Both islands suffered greatly from the attacks of pirates.

LÉRIS, lā'rēs', Claire Josèphe Hippolyte. The correct name of the French actress better known as Mademoiselle Clairon (q.v.).

LERMA, lâr'mȧ, Francisco de Sandoval y Rojas, Duke of (1552–1625). A Spanish statesman. He gained an ascendancy over Philip III when the latter was Prince of Asturias and after his accession to the throne in 1598 became his Prime Minister, with the title of Duke of Lerma. He practically ruled Spain until 1618. The peace with England in 1604 and the truce with the Low Countries in 1609 are patent examples of the failure of his foreign policy, while the brutal persecution and expulsion of the Moriscos in 1609 and 1610 was a blow from which Spain never recovered. His finance measures were equally futile—the debasing of the coinage (copper money doubled in value, e.g.) and high-sounding edicts against luxury and against the making of silver plate. But, despite all these failures, his influence over the King never waned until his own son, the Duke of Uceda, plotted against him. When he saw that his fall was almost certain, he tried to induce Pope Paul V to grant him a cardinal's hat and succeeded early in the very year in which he fell. The unpopular Minister was forced to restore a large part of the ill-won perquisites of his administration when Philip IV succeeded to the throne in 1621. For a full account of the years of his power, consult Modesto Lafuente, *Historia general de España*, vol. xv (Madrid, 1855), where there are also full references to contemporary authorities.

LERMINA, lâr'mē'nȧ', Jules (Hippolyte) (1839–). A French journalist and novelist, born in Paris. He worked on several papers and finally became editor in chief of *Le Soleil*. In the *Corsaire* he vigorously attacked the Empire; he was arrested in 1867 for his part in the disturbances at the cemetery of Montmartre and was imprisoned; on his release he founded the *Satan*, which was soon repressed, like the *Corsaire*. Afterward he was imprisoned for three months because of his republicanism and in 1870 proposed the impeachment of the Emperor and was sentenced to two years in prison, regaining his liberty on the downfall of the Empire. His historical works include: *Histoire anecdotique illustrée de la Révolution de 1848* (1868); *Histoire de cent ans* (1884); and the valuable *Dictionnaire universel illustré de la vie française contemporaine* (1884). He wrote three plays—*La lettre rouge*, *Turenne*, and *La criminelle;* and many novels, using the pseudonym William Cobb as well as his own name. Among these stories are: *Les mystères de New York* (1874); *Les mille et une femmes* (1879); *Le fils de Monte Cristo* and *Le trésor de Monte Cristo*, continuing Dumas (1885); *Alise* (1893); *Calvaire d'amour* (1912). He translated Shakespeare (1887–98). In a different field are *La science occulte* (1890) and *Magie pratique* (1910).

LERMOLIEV, lĕr-mō′lyĕf, IVAN. The pseudonym of the Italian art critic Giovanni Morelli (q.v.).

LERMONTOV, lyĕr′môn-tôf, MIKHAIL YURIEVITCH (1814–41). The greatest Russian poet after Pushkin. He was born at Moscow and was of Scottish ancestry (his name is believed to be the Russianized form of Learmont). He lost his parents at an early age and was reared by his grandmother, who spared neither money nor time in giving him a good private education. In 1828, after a few years' sojourn in the Caucasus, he entered the school for nobles attached to the Moscow University and in 1830 the university, from which he was expelled in 1832 for some trifling escapade. He then entered a military school at St. Petersburg and became an officer of the Imperial Guard Hussars in 1834, leading the life common to ordinary officers of that day. It was in this period and under such demoralizing influences that he dashed off his earliest poems—*The Peterhof Fête, The Lancer's Wife, Mongo,* and others. He first attracted general attention by a poem written in 1837, after Pushkin's death, "On the Death of a Poet," in which he openly reproached the courtiers for Pushkin's death. This so displeased Nicholas I that he sent him to serve in the Army of the Caucasus as an ensign. Pardoned in 1838, he returned to St. Petersburg, but in 1840, after a duel with Barante, son of the French Ambassador, he was again sent to the Caucasus. Here he was killed in a duel by a comrade, Major Martinov, who thought himself described in Grushnitsky, a character in Lermontov's *The Hero of our Time.*

A purely subjective poet, he was alone in society, little understood by his friends, who always feared him and sometimes hated him for his merciless ridicule and stinging satire. He was in this and other respects the Byron of Russia, and in striving after intellectual heights he breathed freely only when away from "loathsome society" in the high regions of the Caucasus, which produced an indelible impression on him in his childhood, and which he has immortalized in his poetry. Lermontov began one of his best longer poems, "The Demon," when barely 15 and continued rewriting it until his death; yet careful study reveals little difference in the power of its various drafts. His fame spread like wildfire after the ill-starred "On the Death of a Poet," and when, a short time later, he published his "Song of the Merchant Kalashnikov," he was already recognized as the greatest Russian poet. This ballad, a clear and poetic vision of Russia's past, is the finest specimen of its kind in Russian literature—an artistic production, faithfully preserving the spirit and form of the folk song. Besides various dramatic and epic works, he wrote a great number of lyric poems. *The Hero of our Time,* a prose novel consisting of five separate sketches, appeared with a preface in 1841, but installments of it were originally published in a periodical during 1839–40. Besides being noteworthy as the first Russian psychological novel, this work (whose promised sequel never appeared) has considerable autobiographical interest.

The best editions of Lermontov's works are those by P. A. Viskovaty (1891), A. I. Vvedensky (1891), I. M. Boldakov (1891), and D. E. Abramovitch (1910–13). The last contains comprehensive biographical and bibliographical data. Most of Lermontov's works are available in French and German translations. Among the latter the work of F. F. Fielder is especially notable for its remarkable fidelity to the original. In English have appeared *The Hero of our Time,* translated by T. Pulszky (1854), anonymously (1854), by R. I. Lipmann (1866), and by Ivan Nestor-Schnurmann (Cambridge University Press, 1899)—the last two contain biographical sketches of the author, *The Circassian Boy* (*Mtsyri*), translated by S. S. Conant (Boston, 1875); and *The Demon,* translated by Stephen (London, 1875) and by Francis Storr (London, 1894). There is still no adequate literary study of this poet in English. A comprehensive bibliography is given in Wiener's *Anthology of Russian Literature* (New York, 1903).

LERNA, lĕr′nȧ, HYDRA OF, **LERNÆ′AN HYDRA.** See HERCULES; HYDRA.

LERNER, lĕr′nĕr, TINA (1890–). A Russian pianist, born at Odessa. She began her musical education at a very early age in her native town, and at six entered the conservatory at Moscow, where she remained until 1900. Thereupon she went for further study to Godowsky, and made her début in St. Petersburg (Petrograd) in 1903, meeting instantly with most emphatic success. Her European reputation dates from her tour of Germany in 1905. She made her first visit to the United States in 1908, when she was received with marked favor, which upon subsequent visits became enthusiastic admiration. In 1909 she was married to Louis Bachner, a member of the faculty of the Peabody Institute of Baltimore. She is remarkable for her command of tonal color and poetic insight and at her best in works of an intimate character.

LEROLLE, le-rŏl′, HENRI (1848–). A French painter, born in Paris. He studied under Lamothe and received a first-class medal at the Salon of 1880 and a gold medal at the Paris Exposition (1900). Among his works are: "The Communion of the Apostles" (1878); "At the Organ" (1885, Metropolitan Museum, New York City); and "In the Country" (1880), bought by the state; portrait of the artist's mother; "The Arrival of the Shepherds" (Carcasonne Ville and the Sorbonne, Paris). His favorite subjects are large landscapes with few figures, sympathetically and realistically executed but without much power. His effects of evening light are notable.

LE ROND, le rôɴ′, JEAN. See D'ALEMBERT.

LEROS, lĕr′ŏs, or **LERO,** lĕr′ô. An island of the Grecian Archipelago, one of the Sporades, under military occupation by Italy as a consequence of the Turco-Italian War (Map: Greece, H 6). It is situated about 30 miles south of Samos. Its area is estimated at from 20 to 25 square miles. The surface is hilly, the extreme elevation being 1086 feet above the sea, but the soil fertile, producing grapes, olives, and grain. Pop. (est.), 3000, mainly Greeks. The islanders are mainly engaged in the carrying trade and sponge fishing. The chief town, Leros or Marina, has a castle and about 1500 Greek inhabitants.

LE ROSSIGNOL, le rŏs′ĭ-nyŏl′, JAMES EDWARD (1866–). An American economist, born in Quebec, Canada. He graduated at McGill University in 1888 and at Leipzig (Ph.D.)

in 1892, and studied also at Clark University. At Ohio University he was professor of psychology and ethics (1892–94), at Denver professor of economics (1894–1911), and at the University of Nebraska, where he had temporarily held a chair in 1908–09, head professor of political economy (after 1911) and director of the School of Commerce (after 1913). He lectured at McGill in 1900 and at the University of Wisconsin in 1903 and in 1906 made investigations in New Zealand. He is author of *Monopolies, Past and Present* (1901); *Orthodox Socialism* (1907); *Little Stories of Quebec* (1908); *State Socialism in New Zealand* (1910).

LEROUX, le-rōō′, Hector (1829–1900). A French painter of classical subjects, born at Verdun. He studied under Picot and won the second Prix de Rome in 1857 with his "Lazarus." Many of his works are owned in America. The best include "A New Vestal Virgin" (1863, Museum of Verdun); "Columbarium" (1864, acquired by the state); "The Slave of Horace"; "Roman Ladies at the Tomb of their Ancestors" (Metropolitan Museum, New York); the very powerful "Messalina" (1868); the "Vestale Tuccia" (1874, Corcoran Gallery, Washington); "Amata"; "News from Outside" (1891); "Hagar and Ishmael" (1892); "Pericles and Aspasia Visiting Phidias"; "Joan of Arc at Domremy" (1900). He is not merely classical in his subjects, but seems to prefer the unromantic lack of action and absence of any emotion unless it be commingled with cold dignity.

LEROUX, Henri, called Hugues (1860–). A French journalist and romance writer, born at Havre. He contributed to the *Revue Politique et Littéraire*, the *Temps, Matin, Journal, Figaro*, etc., articles written in a peculiarly pleasing style, which also characterized his romances, such as *Un de nous* (1886), *Les larrons* (1890), *Les amants byzantins* (1897), *Le maître de l'heure* (1897), and *Le fils à papa* (1900). He published a book upon *La Russie souterraine* (1885) and a Nihilist novel, *L'attentat Sloughine*, the same year, but afterward turned his attention to the underground life of his own city and issued *L'enfer parisien* (1888). He visited the United States at the beginning of the twentieth century and lectured at Harvard. In 1915 he came again to America, to lecture on the attitude of France towards the European War. His more serious works include: *Notre patron Alphonse Daudet* (1888); *Les jeux du cirque et la vie foraine* (1889); *Portraits de cire* (1891); *Marins et soldats* (1892); *Les mondains* (1893); *Nos filles; qu'en ferons-nous?* (1898). Among his travel sketches are: *Au Sahara* (1891); *En yacht* (1892); *Notes sur la Norvège* (1894); *Prisonniers marocains* (1905). He adapted Dostoyevski's *Crime and Punishment* for the stage, besides writing the play *L'Autre France* with Decourcelle (1900) and the opera libretto *Le roi aveugle* (1906). Also in 1906 he wrote *L'Heureux ou l'heureuse.*

LEROUX, Pierre (1797–1871). A French radical publicist and philosopher, born in Paris. After studies at the Lycée Charlemagne he founded (1824) the *Globe*, an organ of literary and social reformers, which in 1831 became converted to the socialism of Saint-Simon. Leroux then (1832) became editor of the *Revue encyclopédique*, and in collaboration with Jean Reynaud undertook the *Encyclopédie nouvelle*, to continue the philosophic propagandism of the old *Encyclopédie*. (See Diderot.) In 1839 he summed up his philosophic creed in *De l'humanité, de son principe et de son avenir*, teaching development towards perfection. In 1841 he joined with George Sand and Viardot to found the *Revue Indépendante*, translated Goethe's *Werther* in 1843, and in 1848 was an ultraradical delegate to the National Assembly. After the coup d'état (1851) he sought refuge in Jersey and at Lausanne, but he returned in 1869. His more prominent writings were: *Du christianisme et de ses origines démocratiques* (1848); *Malthus et les économistes, ou y aura-t-il toujours des pauvres?* (1848); *Job*, a drama (1865).

LEROUX, Xavier Henri Napoléon (1863–). A French composer, born at Velletri, Italy. He was a pupil of Dubois and Massenet at the Paris Conservatory, and won the Prix de Rome in 1885 with his cantata *Endymion.* In 1896 he was appointed professor of harmony at the Paris Conservatory. He wrote a mass with orchestra, several motets, and a dramatic overture, *Harald.* But his importance rests upon his operas: *Evangéline* (1895), *Astarté* (1900), *La reine Fiammette* (1903), *Vénus et Adonis* (1905), *William Ratcliffe* (1906), *Théodora* (1906), *Le Chemineau* (1907). The last named was heard in the United States (New Orleans) in 1911. Two other operas, *Le carillonneur* and *La fille de Figaro*, are still in manuscript.

LE ROY. A village in Genesee Co., N. Y., 26 miles southwest of Rochester, on the Buffalo, Rochester, and Pittsburgh, the Erie, and the New York Central and Hudson River railroads (Map: New York, B 5). It is a manufacturing and residential town and produces salt, canned fruits, cotton goods, food products, medicines, and agricultural implements. There are also limestone quarries. The government is vested in a board of trustees, with the president, who is annually elected, as executive head. The water works are owned by the village. Le Roy was the home of Ingham University, one of the first colleges for women. Pop., 1900, 3144; 1910, 3771.

LEROY, le-rwä′, Jean Jacques Joseph, known as Leroy d'Etiolles (1798–1860). A French surgeon, born in Paris. In 1822, while a medical student, he invented a set of instruments for performing the operation of lithotrity (q.v.) and was the first successfully to perform that operation. His works include: *Exposé de divers procédés employés pour guérir de la pierre* (1825); *De l'extraction des corps étrangers* (1854); and his translation into French of Cooper's *Dictionary of Surgery.*

LE ROY, Marin. See Gomberville, Marin Le Roy, Sieur du Parc et de.

LEROY, William Edgar (1818–80). An American naval officer. He was born in New York City, entered the navy as midshipman in 1832, and became a commander in 1861, a captain in 1866, a commodore in 1870, and a rear admiral in 1874. He commanded the *Keystone State* in the engagement with Confederate ironclads off Charleston in January, 1863, and the *Ossipee* at the battle of Mobile Bay, on Aug. 5, 1864. From 1876 to 1879 he commanded the South Atlantic squadron, and in 1880 retired.

LEROY-BEAULIEU, le-rwä′-bō′lyẽ′, Anatole (1842–1912). A French publicist, brother of Pierre Paul, born at Lisieux (Calvados). He devoted himself to the study of the history of art and literature and published in 1866 *Une troupe de comédiens*, followed in 1875 by *La re-*

stauration de nos monuments historiques devant l'art et devant le budget. In 1811 he became professor of modern history at the Ecole Libre des Sciences Politiques and in 1887 was made a member of the Academy of Moral and Political Science. In the *Revue des Deux Mondes,* with which he became connected soon after the publication of his second work, he published a number of important political and social studies, subsequently reprinted in book form. Chief among these are *L'Empire des Tsars et les Russes* (1887–89), an excellent treatise on the history, politics, and social life of Russia, based on personal observation; *Un homme d'état russe* (*Nicolas Milutine*) (1884); *La France, la Russie, et l'Europe* (1888); *La Russie et la crise russe* (1908). Various phases of contemporaneous social development are treated in *Les catholiques libéraux, l'église et le libéralisme depuis 1830* (1885); *La révolution et le libéralisme* (1890); *Les juifs et l'antisémitisme, Israël chez les nations* (1893); *Les doctrines de haine: l'antisémitisme, l'antiprotestantisme, l'anticléricalisme* (1902); *Les congrégations religieuses et l'expansion de la France* (1903); *Christianisme et Socialisme and Christianisme et Démocratie* (1905).

LEROY-BEAULIEU, Pierre Paul (1843–1916). A French economist, brother of Anatole. He was born at Saumur, studied at Paris, Bonn, and Berlin, and later wrote for French publications. In 1867 he published his first large work, *L'Influence de l'état moral et intellectuel des populations ouvrières sur le taux des salaires.* In 1872 he became professor of finance at the Ecole Libre des Sciences Politiques, and in 1880 professor of political economy at the Collège de France. A leading exponent of free trade, he founded the *Economiste Français* in 1873. He was made a member of the Academy of Political and Social Science and an Officer of the Legion of Honor and received honorary degrees from Bologna, Edinburgh, Dublin, and Cambridge. Among his works are: *La colonisation chez les peuples modernes* (1873); *Précis d'économie politique* (1888); *L'Etat moderne et ses fonctions* (1889; Eng. trans., 1891); *Traité théorique et pratique d'économie politique* (1895); *Le Sahara, le Sudan et les chemins-de-fer transsahariens* (1904); *L'Art de placer et gérer sa fortune* (1906); *La question de population* (1913). His son, Pierre, published *Les nouvelles sociétés anglo-saxonnes* (1897); *Rénovation de l'Asie* (1900; Eng. trans., 1900); *Les Etats-Unis au XXe siècle* (1904; Eng. trans., 1906).

LERP INSECT. A term derived from an aboriginal word meaning 'sweet,' and referred to an insect (*Psylla eucalypti*) which has its habitat in the mallee regions of Victoria, Australia. Its secretion, a manna, is found on the leaves of the mallee (*Eucalyptus dumora*); and from it a chemical substance called *lerpamyllum* is derivable. (Consult second supplement to Watt's *Dictionary of Chemistry,* 1875.) According to Westgarth, the natives of the Wimmera prepared a luscious drink from the laap (or lerp) of the mallee. See Manna.

LERWICK, lĕr′wĭk *or* lĕr′ĭk. The chief town of the Shetland Islands (q.v.), Scotland, on Mainland, on Bressay Sound, 110 miles northeast of Kirkwall (Map: Scotland, G 1). Fishing is the chief branch of industry and is important. The harbor is large and safe. The town has a public pier 300 feet in length and is defended by Fort Charlotte, built in the time of Cromwell. Lerwick is one of the principal Scottish stations for the royal naval reserve, and the seat of the Shetland law courts. It contains a fine modern town hall (1881) with good stained-glass windows, an excellent secondary school known as the Anderson Institute, and a small picture gallery. Pop., 1901, 4061; 1911, 4664.

LÉRY, lå′rĕ′, Jean de (1534–1601). The first Protestant minister who preached on the American continent. He was a Calvinist and, with others, was sent from Geneva in 1556 to preach among the Huguenot colonists at Rio de Janeiro, by Coligny and Villegagnon. The ministers and the patron quarreled. After many sufferings and dangers they returned to France. Léry wrote *Histoire d'un voyage fait en la terre du Brésil* (1578).

LESAGE, le-säzh′, Alain René (1668–1747). A French novelist and dramatist, born in Sarzeau, Brittany, May 8, 1668, famous for his *Gil Blas.* Left an orphan at 14 and despoiled by his uncles of his patrimony, he went to Paris in 1690, studied for the law, married in 1694, gave up law for letters, won the patronage of the Abbé de Lyonne, from whom he received a pension of 600 livres, and supported himself by hack work in not always faithful translations from the Spanish (*Théâtre Espagnol,* 1700; Avellaneda's unauthorized *New Adventures of Don Quixote,* 1704; etc.). Lesage's original work in both fiction and drama begins with 1707 with the comedy *Crispin, rival de son maître,* and the novel *Le diable boîteux,* the idea for which was borrowed from Guevara's *Diablo Cojuelo* (1641) and the details from other sources, though none could question the originality of its wit and spirit. Then followed Lesage's greatest comedy, *Turcaret* (1709). In this play Lesage fiercely assailed the taxgatherers or *traitants.* Such was their power that they could keep this play off the stage for a while, but the Dauphin took sides with Lesage and *Turcaret* was put on. His trouble with the Théâtre Français led him to work thereafter for the rival and inferior Théâtre de la Foire, for which Lesage wrote a host of farces and light operettas, once popular but now forgotten, giving his ripest thought meantime to *Gil Blas,* his greatest novel, begun in 1715, continued in 1724, completed in 1735, and revised in 1747. *Gil Blas* is derived in part from the following works: *Disgrazia del conte d'Olivare,* in a French translation; from a French work founded on the *Anecdotes du comte-duc d'Olivares,* by M. de Valdory; from the *Histoire du comte-duc avec des réflexions politiques et curieuses* (Cologne, 1683). Lesage also borrowed from the life of Obregon and from a number of Spanish narratives or plays. The *Lazarillo de Tormes* is a prototype of *Gil Blas.* The borrowed episodes of *Gil Blas* constitute about one-fifth of the whole. It tells the story of a young rogue who is cast upon the world and has innumerable adventures which he recounts in a light, satirical, low, and often cynical vein. Lesage wrote also a French adaptation of the Spanish *Guzman d'Alfarache* (1732), a picaroon novel, and the similar though more independent picaroon stories, *Estevanille Gonzales* (1734) and *Le bachelier de Salamanque* (1736), as well as *Les aventures du chevalier de Beauchesne* (1732), founded on contemporary memoirs, all works little read, and not likely to be much read, but not without interest as experiments in realistic fiction.

Lesage's domestic life was happy and uneventful. He lived respectably, on the borderland of Bohemia, and if he died poor it was rather because he was independent than because he was reckless, his good humor being always restrained by a sane judgment. In his lifetime, though always popular, he was enjoyed rather than appreciated, for, though not a creative genius, he was so keen an observer and so remarkable an assimilator as to be in several ways an innovator; not the father of realism, but its prophet. *Le diable boîteux* is a satire on contemporary Parisian society, under a Spanish veil, owing more to La Bruyère's *Caractères* than to Guevara. Keys were soon provided in abundance, and even now the allusions to Fontenelle, Ninon de l'Enclos, Voltaire, and others are unmistakable. *Crispin* and *Turcaret,* too, are prose pictures of Parisian life, the former farcical, the latter a cruelly realistic satire on mercantile pettiness, provincial narrowness, and most of all on the new plutocracy. This satiric realism finds its final expression in *Gil Blas,* the story of a self-made man and studied more from French life than from any Spanish romance. At least four men were then living in France—Dubois, Alberoni, Barjac, and Gourville—valets or favorites, whose adventures might have suggested those of Lesage's Spanish hero. The story aims, through the experiences of a checkered life, to show how character is formed by environment, how impressions rouse reflection, reflection stirs conscience, and both react on conduct so as gradually to transform it. That is the moral, and to draw it Lesage paints the world as he finds it with keen understanding and the charity of wisdom. So *Gil Blas* has endured for nearly two centuries as a gospel of a worldly-wise man's common sense. Lesage's permanence in French literature seems more assured to-day than at any time since his death, which occurred in Paris, Nov. 17, 1747.

Lesage's works are best edited by Renouard in 12 volumes (1821), to be supplemented by *Le Théâtre de la Foire* (10 vols., 1737) and unpublished manuscripts in the French National Library.

Saintsbury, *Essays on French Novelists* (London, 1891); Eugène Lintilhac, *Grands écrivains français* (Paris, 1893).

LES′BIA. The name under which Catullus in his love poems celebrates the beautiful and shameless Clodia.

LESBIAN POETS, The. A term used to designate the four poets of Lesbos, Terpander, Alcæus, Arion, and Sappho.

LESBOS, lĕz′bŏs. An island in the Ægean sea, midway between Smyrna and the Dardanelles. It was formerly part of the Ottoman Empire, but was taken over by Greece in 1913 after the Balkan wars had resulted in Turkey's defeat. Since then it has remained in Greek hands. The island is frequently called Mytilene from the name of its chief city in ancient and modern times (now also called Kastro) (Map: Greece, F 2). Area, about 675 square miles. It is mountainous and densely forested and is nearly cut in two by the Bay of Kalloni, that indents from the southwest; the highest peak is Mount Olympus (Hagios Elias), reaching an altitude of 3077 feet. The principal products are olive oil (about 15,000 metric tons a year), valonia, figs, and almonds, and there are tanneries, and silk and soap factories. The imports are grain, flour, sugar, tobacco, alcohol, sulphur, and petroleum. Population about 130,000, of whom about 90 per cent are Greek. Mytilene has upwards of 50,000 inhabitants. Lesbos is famous as the birthplace of the poets Sappho, Alcæus, Terpander, and Arion, of the statesman Pittacus, of the historian Hellenicus, and of the philosophers Theophrastus and Phamas. For the ancient history of the island, see the article on the city of Mytilene, the capital. In 1354 Lesbos was conveyed by the Byzantine Emperor to Francesco Gattilusis, a Genoese noble, whose descendant, in 1462, lost it to Mohammed II. In 1690–98 the Venetians, and in 1821 the Greeks, defeated the Turks in naval battles here. Consult H. F. Tozer, *Islands of the Ægean* (London, 1890), and Georgeakis and Pineau, *Le Folk-lore de Lesbos* (Paris, 1894).

LESCARBOT, lĕ′skär′bŏ′, Marc (c.1570–1630). A French traveler and writer, born at Vervins. He studied law and became an advocate before the Parliament of Paris. With his friend Pontrincourt he went to Canada in 1605 to relieve the settlement at Port Royal. After the monopoly of the fur trade was broken, the settlement was abandoned, and in 1607 he returned to France, where he published *Histoire de la Nouvelle France* (Paris, 1609; 2d ed., 1612). The edition of 1618 contains in addition *Muses de la Nouvelle France.* The history describes the voyages of Verazzani, the settlement in Florida, the expedition to Brazil, and De Monts's colony in Acadia, the last being the first attempt to found an agricultural colony in America. Later he was secretary of the French Embassy in Switzerland and wrote some books of travel. Consult H. P. Biggar, "Marc Lescarbot of Vervins, the French Hakluyt," in the *American Historical Review,* vol. vi (New York, 1901).

LESCAUT. See Manon Lescaut.

LESCHES, lĕs′kēz (Lat., from Gk. Λέσχης). One of the so-called cyclic poets (q.v.), who flourished in the earlier half of the seventh century B.C. He was born at Pyrrha, near Mytilene, and is usually regarded as the author of the epic entitled *The Little Iliad* (Ἰλιὰς ἡ ἐλάσσων, or Ἰλιὰς μικρά), in four books. This poem, which was intended as a supplement to the *Iliad* of Homer, narrated the events after the death of Hector—the contest of Ulysses and Ajax for the arms of Achilles, the fate of Ajax, the exploits of Philoctetes, Neoptolemus, and Odysseus, and the final destruction of Troy. From the last part of the work, which, like the first part of the poem of Arctinus, was called *The Destruction of Troy* (Ἰλίου Πέρσις), Pausanias makes several quotations describing the sacking of Troy and the taking away of the prisoners. Consult: Aristotle, *Poetica,* 23; Müller, *Fragmenta Historicorum Græcorum* (Paris, 1868–83); D. B. Monro, edition of *Odyssey,* xiii–xxiv, pages 362–371 (Oxford, 1891); Christ-Schmid, *Geschichte der griechischen Litteratur,* vol. i (6th ed., Munich, 1912).

LESCHETIZKY, lĕsh′e-tĭts′kĭ, Theodor (1831–1915). An Austrian pianist, born in Lancut, near Lemberg, Galicia. As a piano virtuoso he was very favorably received in London, Holland, Berlin, and Vienna; and in a lesser degree for his compositions, which include *Souvenirs* *d'Italie*, *Suite à la campagne*, and many other similar pieces, as well as an opera, *Die erste Falte*, first given in Prague in 1867, and afterward at Wiesbaden in 1881. He became especially famous as a teacher—one of Paderewski's principal instructors, he gained great popularity among American students abroad. His own teachers were his father, Czerny, and Sechter. In 1852 he joined the faculty of the St. Petersburg Conservatory, and acted as conductor of the orchestra of the Grand Duchess Helen during the absence of its regular conductor, Rubinstein. Ill health compelled him (in 1878) to leave the country. In 1880 he took up his residence in Vienna as a teacher. Consult A. Potocka, *Th. Leschetizky* (New York, 1903), and Annette Hullah, *Theodor Leschetizky* (London, 1906).

LESCOT, l*e*-skō′, Pierre (c.1510–78). One of the greatest French architects of the Renaissance. Little is known of his life. He was born between 1510 and 1515 and is called a Parisian by Jean Goujon in his introduction to Martin's translation of Vitruvius. His praises were sung by the poet Ronsard, who wrote him an epistle from which we know that he was Seigneur de la Grange du Martroy, Seigneur de Clagny, Abbé Commendatoire de Clermont (1554), and canon of the cathedral of Notre Dame, Paris. His first known work was the rood screen of St. Germain l'Auxerrois, Paris (1541–44), and he designed the architectural part of Jean Goujon's Fountain of the Innocents, in Paris. The plans for Hotel Carnavalet, Paris, are also attributed to him. His masterpiece was the southwest angle of the Louvre, begun in 1546, by which the renovation of the old Gothic palace was commenced. Lescot was the real founder of the purely classic school in France, previous work having been mainly the result of an amalgamation of Gothic and classic elements. The view advanced by Reginald Blomfield in his *History of French Architecture* (London, 1911) that Lescot was no real architect, but a clever courtier and business manager, who employed Goujon (q.v.) to design all his architecture, has not found general acceptance although presented with much learning. Consult the work just cited, also Adolphe Berty, *Les grands architectes français* (Paris, 1860), and Léon Palustre, *La renaissance en France* (ib., 1880).

LESDIGUIÈRES, lȧ′dē′gyâr′, François de Bonne, Duc de (1543–1626). An able French general, born at Saint-Bonnet-de-Champsaur and educated at Avignon and at Paris in the Collège de Navarre. He suddenly gave up the law and entered the army under Bertrand de Gordes, but soon left it to join the Protestant party. He was in the thick of the religious civil war and did much for the cause of Henry IV by carrying on a guerrilla warfare in the mountains. He commanded the King's armies against Charles Emmanuel I of Savoy with great success (1591–92); and in 1597 raised an army at his own expense, beat the Spaniards, and in the following year again defeated the Duke of Savoy. He succeeded in making himself practically ruler of Dauphiné, although his dictatorship was looked upon with some distrust by Henry. He was made marshal of France in 1608, and three years afterward Duke of Lesdiguières. Under Louis XIII Lesdiguières fought for the cause of Savoy against the Spaniards. He finally abjured Calvinism and commanded against the Huguenots, being rewarded for his services by being made Constable of France and a member of the Order of St. Esprit. Consult Dufayard, *Le connétable de Lesdiguières* (Paris, 1892).

LESE MAJESTY, lēz mȧj′ĕs-tĭ (Fr. *lèse-majesté*, from *léser*, to injure + *majesté*, majesty, from Lat. *læsa*, p.p. of *lædo*, to hurt + *majestas*, greatness, dignity), or **LEZE MAJESTY.** In the most general sense, any act tending to injure or impair the dignity or respect of the sovereign. At the common law and to-day in England, as well as in the United States, such an act is cognizable as an offense only when it is grave enough to amount to treason. But in Germany and perhaps some other continental countries lese majesty comprehends even such minor offenses as the publication or public utterance of words derogatory to the administration of the state or to the person of the reigning sovereign. See Treason; Liberty of the Press; Libel.

LES EYZIES, lā-zā′zē′. See Paleolithic Period.

LESGHIANS, lĕz′gĭ-*a*nz, or Lesghian-tchetchen. A group of peoples of the Caucasus, approximately numbering 600,000, comprising the eastern division of Lesghians proper, the more central Tchetchenzes, and some other peoples, whose exact relations are still somewhat in doubt. The Lesghians, who mainly inhabit Daghestan (sometimes called Lesghistan), comprise the Avars, Dargha, Kurins, Kazi-Kumuks, and other tribes. The Tchetchenzes comprise the Tchetchenzes proper, the Karabulaks, Ingushes, Tushes, etc. The Georgian name for the Tchetchenzes is Kists (q.v.). They call themselves Naktchuoi. Some authorities (Müller, 1879; Brinton, 1890) classify the Lesghians and Kists (Tchetchenzes) as two different groups. Keane (1896) considers that some of the languages of this region of the Caucasus, as the Ude, Kubachi, Andi, etc., "must for the present be regarded as so many stock languages," while according to Uslar some of the languages of southern Daghestan are practically "inflectional." The Lesghian group includes many of the wilder and more independent tribes of the Caucasus. Shamyl, whose capture by the Russians in 1859 ended a thirty years' heroic struggle for Lesghian independence, was an Avar. Their physical features, too, are less prepossessing than those of the Georgians, Circassians, etc. The Lesghians (particularly the eastern tribes) are very brachycephalic, with a fairly high stature. The face sometimes suggests Mongolian admixture, the nose Semitic. Light-gray eyes and fair hair are rather common among them. They are an intelligent, brave, and hardy people. Hunting, cattle breeding, smithing, and carpet weaving are their chief occupations. The Lesghians have been converted to Islam. Anthropological and ethnological information about the Lesghians will be found in the following works: Wagner, *Schamyl* (Leipzig, 1854); id., *Die Völker des Kaukasus und ihre Freiheitskämpfe gegen die Russen* (Berlin, 1855); Sir A. T. Cunninghame, *Eastern Caucasus* (London, 1872); Rittich, *Die Ethnographie Russlands* (Gotha, 1878); Erckert, *Der Kaukasus und seine Völker* (Leipzig, 1885); Chantre, *Recherches anthropologiques dans le Caucase* (Lyons, 1885–87); De Morgan, *Recherches sur les Origines des Peuples du Caucase* (Paris, 1889); Hutchinson and others, *Living Races of Mankind* (London, 1901); and the ethnological map of Daghestan, published by Komarov.

LE SICILIEN, ou L'Amour Peintre, le sē̆'-sē̆'lyäN' o͞o lȧ'mo͞or' păN'tr' (Fr., The Sicilian, or Love as a Painter). A comedy by Molière (1667).

LESKIEN, lĕs'kē-*e*n, August (1840–). A German philologist. He was born at Kiel and studied there, at Leipzig, and at Jena, where he specialized in Slavic linguistics under Schleicher (1866–67), and where he was made assistant professor of comparative philology in 1869. A year later he went to Leipzig to give the first course there in Slavic languages. With Burgmann he edited *Litauische Volkslieder und Märchen* (1882). In 1884 he became an editor of Ersch and Gruber's *Realencyklopädie.* His other writings include: *Indogermanische Chrestomathie* (1869), with Ebel, Schleicher, and Schmidt; *Handbuch der altbulgarischen Sprache* (5th ed., 1910); *Die Deklination im Slawisch-Litauischen und Germanischen* (1876); *Ablaut der Wurzelsilben im Litauischen* (1884); *Untersuchungen über Quantität und Betonung in den slawischen Sprachen* (1885–93); *Die Bildung der Nomina im Litauischen* (1891); *Grammatik der altbulgarischen Sprache* (1909).

LESKOV, Nicholas. See Lieskov, Nikolai Semionovitch.

LES'LEY, or **LESLIE,** John (1527–96). A Scottish prelate, statesman, and historian, the natural son of the parish priest of Kingussie, Inverness-shire. He graduated M.A. at King's College, Aberdeen and studied later at Poitiers, Toulouse, and Paris. In 1547, in his twentieth year, he became a canon of Aberdeen Cathedral. In 1549 he went to France, where he studied canon and civil law at the universities of Poitiers and Paris. He returned to Scotland in 1554 to take up an appointment as professor of canon law in his alma mater, and in 1559 he was appointed canon and prebendary of Oyne. He was a strenuous opponent of Knox and of the introduction of Protestantism into Scotland, and was one of the commissioners sent to invite Queen Mary to Scotland; on her accession he became her chief ecclesiastical adviser, and in 1566 was made abbott of Lindores and in the same year Bishop of Ross. His loyalty to his Queen subjected him to much dangerous intrigue, and after her imprisonment in Bolton Castle, in 1568, he went to plead her cause at the court of Elizabeth. In 1571 he was imprisoned in the Tower of London for complicity in the projected marriage of Mary to the Duke of Norfolk, for his share in the resulting uprisings in the north of England, and for his attempts to secure Spanish intervention. The confession extorted from him led to Norfolk's execution. In 1573 he was released by Elizabeth, but was banished from the Kingdom. He went to France, and continued to intercede, but unsuccessfully, for his Queen at various continental courts until her death. He visited Rome and received several traveling commissions from the Pope. In 1579 he was appointed suffragan and vicar-general of the diocese of Rouen, where in 1591 his efforts in stimulating the citizens to resist successfully the siege during the Civil War were rewarded by Clement VIII, who appointed him Bishop of Coutances. The disturbed state of the country, however, prevented him from proceeding to his see, and he retired to the Augustinian monastery of Guirtenburg, near Brussels, where he died. He was the author of several Latin and English publications, many of them written in defense of Queen Mary. His most important work is *De Origine, Moribus et Rebus Gestis Scotorum* (10 vols., Rome, 1578), a Latin abridgment in several volumes of the work of Boëthius, with three original volumes in the Scottish dialect, dealing with the period from the death of James I in 1437 to the return of Queen Mary to Scotland in 1561. Consult Andrew Lang, *History of Scotland* (New York, 1904–07).

LESLEY, (John) Peter (1819–1903). An American geologist, born in Philadelphia. He graduated from the University of Pennsylvania in 1838, spent three years assisting Henry D. Rogers in the first geological survey of Pennsylvania, and in 1844 graduated from Princeton Theological Seminary. From 1845, when he returned to the United States after further study at Halle, to 1848 he was a religious worker among the Pennsylvania mountaineers. For two years he served as pastor of a Congregational church at Milton, Mass., then returning to Philadelphia and to his earlier geological interests. He made extensive and important researches in the coal, oil, and iron fields of the United States and Canada and became State geologist of Pennsylvania in 1874. From 1872 to 1878 he served as professor of geology at the University of Pennsylvania; after 1886 he was emeritus professor. The year 1863 he spent in Europe, examining the Bessemer ironworks for the Pennsylvania Railroad Company, and in 1867 he was commissioner to the World's Fair in Paris. In 1884 he was president of the American Association for the Advancement of Science. Besides the many volumes of geological reports which he wrote or edited as State geologist of Pennsylvania, and numerous papers in scientific magazines, he published: *A Manual of Coal and Its Topography* (1856); *The Iron Manufacturer's Guide* (1858); *Historical Sketch of Geological Explorations in Pennsylvania* (1876); *Paul Dreifuss, His Holiday Abroad* (1882). Consult M. L. Ames, *Life and Letters of Peter and Susan Lesley* (2 vols., New York, 1909).

LESLIE, A. See Leven, Earl of.

LESLIE, Charles (1650–1722). A British Jacobite nonjuror and controversialist. He was born in Dublin, Ireland, July 17, 1650, graduated at Trinity College, Dublin, removed to England in 1671 and began the study of law at the Temple, but soon abandoned this for divinity and was admitted to orders in the Church of England in 1680. Returning to Ireland, he was appointed, in 1687, chancellor of Connor. Living in Ireland at the time of the Revolution, he distinguished himself in disputations with the Roman Catholics in defense of Protestantism. Though a zealous Protestant, he adhered to King James, refusing to acknowledge William as his rightful sovereign. After the death of James II he transferred his allegiance to his son, the Pretender, and was sent by some opulent Jacobite gentlemen, in 1709, to Bar-le-Duc to convert him; when the Pretender removed to Italy he accompanied him. In 1721 he obtained permission from George I to return to his native land and took up his abode at Glaslough, Ireland, where he died on April 13, 1722. His theological works excited much attention and have been frequently reprinted. The most prominent are: *Gallienus Redivivus* (1695), which gives the facts of the massacre of Glencoe; *The Snake in the Grass* (1696); *A Short and Easy Method with the Deists* (1698); *A Short and Easy Method with the Jews* (1699); *The Truth of Christianity Demonstrated* (1711). In his political controversies he was the advocate of high monarchical principles. His collected works were published in two volumes (London, 1721), and reprinted in seven volumes (Oxford, 1832). Consult R. J. Leslie, *Life and Writings of Charles Leslie* (London, 1885).

LESLIE, Charles Robert (1794–1859). An American genre painter who practiced in London. He was born in London, Oct. 19, 1794, of American parentage. His father, a watchmaker of Philadelphia, died in 1803, upon his return to that city, leaving his family destitute. Charles Robert was apprenticed to a bookseller, but evinced great aptitude for drawing, and at the age of 17 he drew a portrait of the actor George Frederic Cooke, which was esteemed so excellent that a subscription was raised to enable him to study abroad for two years. In 1811 he went to London and was hospitably received by Benjamin West, president of the Royal Academy. He became one of a group of notable men, among whom were Allston, Coleridge, West, Washington Irving, and John Constable.

His first picture exhibited at the Academy was a melodramatic production, entitled "Murder" (1813). Not until after his visit to Paris, in 1817, did he exhibit his special talent, the painting of humorous historical genre, in his "Sir Roger de Coverley Going to Church." During this period he designed illustrations for Irving's *Knickerbocker History of New York* and *Sketch-Book*, also painting his portrait. In 1822 "Mayday Revels in the Time of Queen Elizabeth" secured his election as an associate of the Academy. In company with Sir Edmund Landseer he visited Sir Walter Scott at Abbotsford in 1824 and painted his portrait. In 1825 he married Miss Stone, a celebrated beauty, and in 1826 he became an Academician. Elected professor of drawing at West Point in 1833, he returned to London after a trial of a few months. In 1838 he was summoned to Windsor to paint the "Queen Receiving the Sacrament after the Coronation," now in Buckingham Palace. He was professor of painting at the Royal Academy from 1848 to 1852, and published his admirable lectures to the students as a *Handbook for Young Painters* (1855). Other works are: *The Memoirs of Constable* (1865), whose merits he was among the first to recognize; an incomplete *Life of Reynolds* (1865); and his own *Autobiographical Recollections* (1860), the two last edited by Tom Taylor. Leslie died at St. John's Wood, London, May 5, 1859.

Leslie is chiefly famous as an illustrator of humorous incidents taken from the great authors. His humor is refined and delightful, and no one has entered more into the spirit of the author. He is a good draftsman and a skillful composer, but the coloring, especially in his later works, is sometimes harsh. The shadows are too black, and there are no middle tones to harmonize them with the light portions. The best known of his pictures is "Uncle Toby and the Widow Wadman" (1831), in the Tate Gallery, London, which possesses also "Falstaff Impersonating the King," "Anne Page and Slender," "Viola and Olivia," portrait of Millais, besides sketches, studies, and replicas, including "Sancho Panza and the Duchess." The South Kensington Museum contains, besides replicas, three subjects from Molière, "The Dinner at Mr. Page's House" (1838), and others. In the collection of Lord Leconfield at Petworth, in Sussex, are the originals of the "Taming of the Shrew" (1832, replica at South Kensington), "Sancho Panza in the Apartments of the Duchess" (1828), and three others. Two of the Sir Roger de Coverley series are at Bowood, in the collection of the Marquis of Lansdowne. In the Philadelphia Academy are a number of replicas and the original of the "Murder of Rutland"; and in the Metropolitan Museum, New York, the portrait of Dr. J. Wakefield Francis. Consult Leslie's *Autobiographical Recollections* (London, 1860).

LESLIE, Frank (1821–80). The name assumed by Henry Carter, an American publisher and journalist, born in Ipswich, England. Son of a glove manufacturer, educated in Ipswich, trained to commerce in London, he showed a natural bent for art and contributed sketches to the *Illustrated London News*, signing them Frank Leslie. These were so cordially welcomed that he gave up commerce and was made superintendent of engraving on that journal. He made himself an expert and inventor in his new work, in 1848 came to the United States, and in 1854 began publishing the first of his many illustrated journalistic ventures, *The Gazette of Fashion. The New York Journal* soon followed, with *Frank Leslie's Illustrated Newspaper* (1855) (now *Leslie's Weekly*), *The Boy's and Girl's Weekly*, *The Budget of Fun*, and many others. He was commissioner to the Paris Exposition of 1867 and received a prize there for his artistic services.

LESLIE, Mrs. Frank, Baroness de Bazus (1828–1914). An American publisher and author, born in New Orleans. Her maiden name was Miriam Florence Folline and she was a descendant of a noble French-Huguenot family, from which she took her title late in life. When Frank Leslie, the publisher, to whom she had been married, died in 1880, leaving his business badly involved, Mrs. Leslie took it in hand and placed it on a paying basis. Before going on a European tour she saw the enterprise syndicated, but on her return she was obliged to effect a reorganization, with herself as president. The circulation of the *Popular Monthly* increased 200,000 in four months under her management. In 1902 she sold out all her publishing interests. In 1891, while abroad, Mrs. Leslie married William Wilde, a brother of Oscar Wilde, but two years later was divorced from him. She was also supposed to have been married several times before meeting Mr. Leslie. By her will she made Mrs. Carrie Chapman Catt (q.v.) residuary legatee, in the expectation that most of her fortune, estimated at more than $1,000,000, would be devoted to woman suffrage. Relatives contested the will. Mrs. Leslie was author of: *From Gotham to the Golden Gate* (1877); *Rents in our Robes* (1888); *Are Men Gay Deceivers? and Other Sketches* (1893); *A Social Mirage* (1899).

LESLIE, Henry David (1822–96). An English composer and conductor, born in London. He studied music with Charles Lucas, became honorary secretary of the Amateur Musical Society in 1847, and served as its conductor from 1853 to its dissolution in 1861. In 1855 he founded the Henry Leslie's Choir, and was its conductor until 1880, when it disbanded. In 1878 it had won the first prize at the Paris International Competition, and in 1882 the society reorganized, only to break up again five years later. In addition, Leslie for a time conducted the Herefordshire Philharmonic Society and the Guild of Amateur Musicians. His compositions, especially the sacred ones, are of considerable merit and include the operas, *Romance, or Bold Dick Turpin* (1857), *Ida* (1864); the oratorios, *Immanuel* (1853), *Judith* (1858); the cantatas, *Holyrood* (1860), *Daughter of the Isles* (1861); a Te Deum and Jubilate in B (1864); etc. He died in Wales.

LESLIE, John. See Lesley, John.

LESLIE, Sir John (1766–1832). A Scottish natural philosopher and mathematician. He was born in Largo, Fife, and was educated at St. Andrews University. In 1785 he entered the Edinburgh Divinity Hall, but devoted much of his time to the sciences, particularly chemistry. In 1788 he left Edinburgh, having given up all idea of following the Church, and after being two years in America as tutor to the sons of a Virginia planter, he returned to London in 1790. From that time till 1805 he was employed in private teaching, traveling, writing, and making experimental researches. His most important work during this period was a translation of Buffon's *Natural History of Birds* (1793), the invention of a differential thermometer, a hygrometer, and a photometer, and the publication of an *Experimental Inquiry into the Nature and Propagation of Heat* (1804), in which were contained his discoveries in the radiation of heat. For this research he became noted, and the Royal Society awarded him the Rumford medals. In March, 1805, after much opposition from the Edinburgh clergy, he was elected professor of mathematics in the University of Edinburgh; and soon after commenced the publication of his *Course of Mathematics*. In 1810 Leslie invented the process of producing cold artificially and froze water by using an air pump and sulphuric acid. (See Liquefaction of Gases.) In 1813 he published a full explanation of his views on the subject; subsequently he discovered a method of freezing mercury. In 1819 he was transferred to the chair of natural philosophy, a position better adapted to his peculiar genius, and in 1823 published one volume of *Elements of Natural Philosophy*, never completed. In 1832 he was knighted, and on November 3 of the same year died at Coates, a small estate which he had purchased near Largo. Besides the instruments above mentioned, he invented an æthrioscope, a pyroscope, and an atmometer.

LESLIE, Thomas Edward Cliffe (1827–82). An Irish economist, born in County Wexford. He was educated at Trinity College, Dublin, and was called to the English bar, but did not practice, as he was elected professor of jurisprudence and political economy at Queen's College, Belfast. A pupil of Maine, he put great stress on the historical study of economics and jurisprudence and specialized in the study of landownership. His *Land System and Industrial Economy of Ireland, England, and Continental Countries* (1870) includes a discussion of the conditions in Belgium and France and insists on the economic superiority of small holdings to the landlord system. A serious loss of manuscript blocked Leslie's scheme for a history of English economics, but he wrote valuable contributions to the gold question and economic method in *Essays in Political and Moral Philosophy* (1879) and contributed largely to periodicals.

LES MISÉRABLES. See Misérables, Les.

L'ESPINASSE, or **LESPINASSE,** lĕs'pē'näs', Julie Jeanne Éléonore de (1732–76). A French writer of remarkable *Letters* and a social leader, born at Lyons. She was the illegitimate daughter of the Countess of Albon. From 1754 to 1764 she lived as companion with the blind Madame du Deffand (q.v.) and presided with her over a fashionable literary salon. They then separated, not amicably, and with the aid of literary friends, especially D'Alembert, with whom L'Espinasse maintained till her death a close though platonic relation, she set up a rival salon as a centre for the younger philosophic school. It was two years after this independent life began, and when L'Espinasse was already 34, that she began to write the letters which have made her famous. The early ones are addressed to a Spaniard, Marquis Gonsalvo de More; the later, to Count de Guibert. Both breathe an ardent though unmerited devotion, and are in their kind little classics of passion. They were published by Guibert's widow in 1800. Consult: Asse, *Mlle. de Lespinasse et Mme. du Deffand* (Paris, 1877), and Ségur, *Julie de Lespinasse* (Paris, 1906). The career of Mademoiselle de L'Espinasse serves as the groundwork for a novel by Mrs. Humphry Ward, *Lady Rose's Daughter* (1903). The *Letters* appeared in English dress at Boston in 1903.

LESQUEREUX, lå'ke-rē', Leo (1806–89). An American botanist, born at Fleurier, Switzerland, of French-Huguenot ancestry. After several years at the academy of Neuchâtel, he went to Eisenach as a teacher of French. Upon his return to Switzerland he became principal in a school at La Chaux de Fonds, but, owing to deafness, he had to give up teaching. His old love of plants led him to study botany as opportunity came, and he published a catalogue of mosses, and later won a prize for a treatise on peat bogs. These monographs won him the friendship of Louis Agassiz and enabled him to travel over northern Europe studying the formation of peat and of coal. In 1848 he went to the United States, lived with Agassiz at Cambridge for a time, and then became the assistant of William S. Sullivant. The two, after expeditions into the mountains of the South, published *Musci Americani Exsiccati* (1856) and *Icones Muscorum* (1864). Afterward Lesquereux again took up his study of coal formation, traveled in Ohio, Pennsylvania, Kentucky, Illinois, and Arkansas, and worked on the geological surveys of these States. Among his reports the "Catalogue of the Fossil Plants which have been named or described from the Coal Measures of North America," the first and the second reports of the Pennsylvania Geological Survey (1880), is the most important work in this field. He also wrote: *Contributions to the Fossil Flora of the Western Territories* (1874–83); *The Flora of the Dakota Group*, edited by F. H. Knowlton (1891); and, with Thomas P. James, the continuation of Sullivant's work, *Manual of the Mosses of North America* (1884). He became entirely deaf in middle life, but was an expert lip reader.

LESSEPS, lĕ'sĕps', *Fr. pron.* lå'sĕps', Ferdinand, Viscount de (1805–94). A French diplomat and engineer, celebrated for the promotion and construction of the Suez Canal. He was born in Versailles, was early employed in the consular service and served as Consul at Cairo, Rotterdam, Malaga, and Barcelona. In 1848–49 he was Minister to Spain. In 1832, while De Lesseps was in Egypt on a visit forced by a quarantine, the idea of constructing a canal across the Isthmus of Suez occurred to him, as it had earlier to Napoleon. He became the friend of Said Pasha, who was later Viceroy, and whose assistance and encouragement were afterward of greatest aid to him. The project of constructing the great intersea canal at Suez remained practically in abeyance until 1854, an interval during which De Lesseps was engaged in diplomatic service. He then again visited Egypt, and in the same year (1854) the Viceroy granted him a concession for the proposed canal and promised the financial assistance of the Egyptian government. His plan of construction, calling for direct communication between the Mediterranean and the Red seas, he defended in a memorial entitled *Percement de l'isthme de Suez, exposé et documents officiels.* Political and engineering objections rendered the success of the project long doubtful and the task of De Lesseps extremely difficult. English engineers were skeptical as to the practicability of the scheme, and the English government, fearing the opening of a shorter route to India which would be under alien control, influenced the Turkish authorities to refuse their consent. M. de Lesseps, however, won the support of Emperor Napoleon III and Empress Eugénie, to whom he was related, and, having secured financial backing, triumphed over all obstructions. Work was actually begun in 1859, and it was finished 10 years later. The formal opening of the canal occurred Nov. 16–20, 1869. De Lesseps, who as president of the company had displayed remarkable engineering and executive ability, was given many honors.

After leaving Suez, De Lesseps was connected with attempts to reclaim the Sahara desert, to construct a canal through the Isthmus of Corinth, and to build a railroad uniting Europe with India. He was also associated with the movement to cut the Panama Canal. His prestige and success at Suez pointed him out as the logical person to direct the new effort. In 1879, at a congress of geographical and engineering experts, it was decided to construct the Panama Canal, and De Lesseps was designated for the presidency of the company contemplated. This company was formed and purchased the Wyse concession, which had been secured from Colombia in 1876. Although of advanced age, De Lesseps entered into the scheme with enthusiasm. His plan, at first, was to build a sea-level canal, but the great and practically insuperable difficulties connected with the Culebra cut and with the regulation of the fluctuating water supply from the Chagres River later caused him to change in favor of locks. The company was formed, with a membership of probably 200,000 persons, and work was begun in 1881. (See Panama Canal.) From the first, the management of the undertaking was characterized by laxness and inefficiency, and expenditures were made with great extravagance. Concerning the developments that followed there has been considerable difference of opinion. As time went on, it became apparent that the canal could not be completed with the available capital, and in 1888 the company was seen to be bankrupt. A liquidator was appointed and took over the management. Scandals concerning the direction of affairs and the financial administration became public, and judicial investigations were begun. That there had been frauds was clearly established, and innocent people had suffered in consequence, but just how far De Lesseps was connected with them and was responsible has remained in doubt. The excitement of the time, however, demanded a victim. In 1893 De Lesseps and his son Charles were convicted at Paris of misappropriation of the funds of the company and were sentenced to fine and imprisonment; the sentence, however, was never executed. That they were technically guilty, however, seemed clear, but it was also established that they were innocent of the intent to defraud.

Bibliography. A record of De Lesseps's many activities will be found in his own *Suez Canal: Letters and Documents Descriptive of its Rise and Progress* (London, 1876); id., *Recollections of Forty Years* (2 vols., ib., 1887); id., *The Isthmus of Suez Question* (ib., 1855); Bunau-Varilla, *Panama: The Creation, Destruction, and Resurrection* (ib., 1914); W. L. Pepperman, *Who Built the Panama Canal?* (New York, 1915). For biographies of De Lesseps, consult Bertrand and Ferrier, *Ferdinand de Lesseps* (Paris, 1887), and Smith, *Life and Enterprises of Ferdinand de Lesseps* (2d ed., London, 1895). See Suez Canal; Panama Canal.

LES'SING, Gotthold Ephraim (1729–81). A German critic and dramatist, born at Kamenz, Jan. 22, 1729; one of the earliest of the great German classical writers. His father, pastor at Kamenz, gave him his early instruction and sent him to a famous school at Meissen, where he learned so rapidly that he was admitted at 17 to the University of Leipzig, where he studied theology, then medicine, and later philosophy and literature. Here his sturdy nature almost immediately asserted itself against the smug platitudes of the Leipzig critics. "I realized," he wrote at this time, "that books might make me learned, but would never make me a man. I sought society to learn life." He took lessons in dancing, fencing, and riding. He translated French plays for the theatrical troupe of Frau Neuber, in whose theatre he learned much of stage technique, and in 1748 she put on his first play, *Der junge Gelehrte.* His early comedies include also *Die Juden*, *Der Misogyn*, *Die alte Jungfer*, and *Der Freigeist*, all more or less under French influence. Soon afterward (1748) he left Leipzig for the University of Wittenberg, whence after a short stay he followed his friend Mylius to Berlin, then as now the centre of German free thought. Here he lived by his pen, writing keen literary criticism and hack translations and venturing on original dramas and lyrics of no great value.

Here, also, Lessing met Voltaire, for whom he worked; but they soon quarreled, for Lessing betrayed a literary confidence of Voltaire's. Critically Lessing profited greatly by the acute Frenchman. He became acquainted with Friedrich Nicolai, Moses Mendelssohn, Karl Ramler, and others, with whom he pursued philosophical and literary studies. Meantime he had taken his master's degree at the University of Wittenberg. In 1754 appeared his *Vademecum für Herrn Samuel Gotthold Lange*, a sharp criticism of Lange's translation of Horace and in general of mediocre literature. In 1755 there appeared in Berlin a collection of Lessing's works in six volumes, containing among other things his new tragedy written under the influence of the English novelist Richardson and the dramatist Lillo, *Miss Sara Sampson*, epoch-making for the German stage as the first bourgeois tragedy.

In the same year Lessing went back to Leipzig. He had started on a three years' period of travel through the Netherlands, England, France, and Italy, as the companion of a wealthy man, when he was recalled at Amsterdam by the disturbances of the Seven Years' War, at a moment when Frederick's deeds were giving to lyric poetry a popular turn, which was welcomed by Lessing in his preface to the *Lieder eines preussischen Grenadiers* of Gleim (q.v.). He went to Leipzig, associated with E. von Kleist, planned *Emilia Galotti*, *Kleonnis*, and a *Faust*, and returned to Berlin in 1758. There he began to issue *Litterarische Briefe*, which cleared the air of choking mawkishness and false formality. With these *Letters* one phase of the classical period of German literature begins and on distinctively national lines. The *Letters* are among the oldest German works generally read to-day, and make Lessing "the Father of German criticism." To this period belong also his three books of fables, his prose tragedy *Philotas*, and his edition of Logau's epigrams.

The *Letters* were continued till 1765, irregularly, amounting finally to 24 volumes. In 1760 Lessing went to the seat of war in Silesia as secretary of General Tauenzien and gathered there materials for the greatest drama and the greatest work of æsthetic criticism that Germany had yet seen, *Minna von Barnhelm* (1767) and *Laokoon* (1766). *Minna von Barnhelm* was the first national drama of Germany; its personages were Germans of the day, drawn from Lessing's Silesian experience, and all of them true to the soil. In every literary field its health-giving influence was felt.

The *Laokoon* attempts to define the demarcation and the limits of poetry and painting. Only the first book was ever written, yet that gradually revolutionized literary taste in Germany. "That long-misunderstood phrase, *Ut pictura poësis*, was set aside. The distinction between the speaking and the plastic arts was clear. All the results of this glorious thought were revealed to us as by a lightning flash," said Goethe. Lessing hastened the publication of the *Laokoon*, hoping to win by it the post of royal librarian at Berlin; but Voltaire had prejudiced the King, and he appointed a third-rate French official to the post. Lessing, however, was called to Hamburg to be critic and adviser of the National Theatre there. Having sold his library to pay debts and rent, with his *Laokoon* unfinished, Lessing left Berlin in April, 1767.

In May, 1767, Lessing began to publish twice weekly the theatrical criticisms (52 in number) known as the *Hamburgische Dramaturgie*. These criticisms soon came to be true essays on dramatic art. The *Dramaturgie* may be regarded as a continuation of the *Laokoon*, and to this day remains the vade mecum of the German stage. It gave the deathblow to French imitation and pointed the way to Schiller and Goethe. In November, 1768, the National Theatre had to close, and Lessing went into the publishing business with Bode.

In 1769 Lessing suspended the *Dramaturgie*, which pirated reprints had made unprofitable, and was attracted to antiquarian studies by the ill-natured attacks of Professor Klotz, of Halle, against whose journal Lessing openly declared war in the *Antiquarische Briefe*. One of the last papers growing out of this campaign was the important essay *How the Ancients Represented Death*.

Famous, but poor, Lessing left Hamburg and in the spring of 1770 became court librarian of the Duke of Brunswick at Wolfenbüttel. He was now eager to found a home, for he had fallen deeply in love with Eva König, widow of a friend who had been a silk manufacturer in Hamburg. In 1775 he visited her at Vienna, where he was welcomed as no German author had ever been. He was recalled thence to accompany the Duke's son to Italy and found that his fame had gone before. In February, 1776, he returned and in October married his betrothed. She and her infant son died in January, 1778. During these years he had completed a remarkable prose tragedy, *Emilia Galotti* (1772). The story is that of Virginia, made familiar by Macaulay's "Lay"; the scene is ostensibly modern Italian, and, though Lessing seems to have avoided all definite political significance, the general application was so obvious that the court of Gotha forbade the representation. Lessing's work as a reformer of the German stage ends here. His *Nathan der Weise* (1779), though still acted, is rather a philosophical work in dramatic form, uniting his ethical and æsthetic studies to the theological controversies that were to fill his later years.

After the death of his wife and son, Lessing sadly yet bravely plunged into three years of intense controversial activity. Of this controversy the immediate cause was Lessing's editing of some posthumous essays by a Hamburg friend, Reimarus, a freethinker, which Lessing was not, though he was an unflinching believer in free speech, in the higher criticism of Scripture, and in the development of doctrine, as he showed in *Die Erziehung des Menschengeschlechts* (1780), a rather brief essay in 100 short numbered paragraphs. He thought and said that it was better error should be taught than freedom of thought stifled, and, further, that "the letter is not the spirit and the Bible is not religion." All these were novel ideas in that generation and peculiarly hateful to Pastor Goeze, of Hamburg, who led a numerous band of obscurantists, while at first Lessing was almost the only defender of free discussion. Lessing's letters in this controversy are remarkable for their eloquence, wit, satiric power, and dramatic vivacity. They mark a distinct advance in German prose style and a permanent gain to the religious life of the German nation. And out of the bitterness of the dispute came as a sweet fruit the dispassionate expression of its results in the dramatic poem of toleration, *Nathan the Wise*, inspired partly by his friendship for Moses Mendelssohn.

The same lofty theme of toleration was pursued during Lessing's closing years in *Die Erziehung des Menschengeschlechts*, the work on education cited above; and its principles appear in the political sphere in *Ernst und Falk, Gespräche für Friemaurer* (1778), whose bold utterance was muzzled by the Brunswick censor. Lessing in these last days wrote as one to whom hard experience had taught its lesson of self-denying wisdom. His mind was still active and eager, but his body was gradually giving way. On a visit to Brunswick he suffered a stroke of apoplexy, and died Feb. 15, 1781.

Lessing, says Goethe, was great by character and tenacity of will. By his plays he gave Germany a national drama; by his criticism, the field of his highest power, he established for his nation true canons of æsthetic and dramatic criticism, freed her from a petrified orthodoxy, and taught her to breathe a more tolerant and loftier Christianity. He himself offered the example of a life devoted to the search for truth.

Lessing's *Works* have been often collected, notably by Lachmann (13 vols., 1838–40; 3d ed., by Muncker, in 22 vols., Stuttgart-Leipzig, 1886–1910). Most of them are published separately. There are translations of the *Laokoon, Minna von Barnhelm, Emilia Galotti, Nathan der Weise,* and many others of his important works in all of the civilized languages.

Braun, *Lessing im Urteile seiner Zeitgenossen* (Berlin, 1884–97); J. Kont, *Lessing et l'antiquité* (Paris, 1894); Ernst Consentius, *Lessing und die Vossische Zeitung* (Leipzig, 1900); R. M. Meyer, *G. E. Lessing* (ib., 1908); Erich Schmidt, *Lessing: Geschichte seines Lebens und seiner Schriften* (3d ed., 2 vols., Berlin, 1909–10). There are English *Lives* by James Sime (New York, 1877), Zimmern (London, 1878), and T. W. H. Rolleston (ib., 1889). For full bibliography, consult Karl Goedeke, *Grundriss zur Geschichte der deutschen Dichtung,* part x (3d ed., Dresden, 1913).

LES′SING, Karl Friedrich (1808–80). A German historical and landscape painter, grandnephew of Gotthold Ephraim Lessing. He was born near Breslau, Feb. 15, 1808, and was a pupil of Dähling at the Berlin Academy. He first devoted himself to landscape and in 1826 obtained a prize with his "Cemetery in Ruins." He accompanied Schadow to Düsseldorf, where he continued his studies, devoting himself to historical paintings. In 1830, when Schadow went to Italy, Lessing occupied his place as director of the academy, exercising great influence upon the Düsseldorf school. His picture "Das trauernde Königspaar" (Mourning Royal Couple) brought him great popularity. In 1837 he received a gold medal at Paris; he was a member of the Berlin Academy and was the recipient of several orders. In 1858 he was appointed director of the gallery at Karlsruhe, where he continued his activity as a painter until his death, Jan. 4, 1880. His work, like that of the Düsseldorf school in general, was at first theatrical, but it gradually became more realistic and virile. His historical paintings were mostly executed in the service of Protestantism. The best known are: "Hussite Sermon" (1836) and the "Martyrdom of Huss" (1850), in the National Gallery at Berlin; "Huss before the Council of Constance" (1842), in the Museum of Frankfort; "Dispute between Luther and Dr. Eck" (1867), in the Gallery of Karlsruhe; "Luther Burning the Pope's Bull" (1853); "Pope Paschal II, a Prisoner of Henry V" (1857), in the possession of the German Emperor. He is also represented in the galleries of Dresden, Leipzig, Cincinnati, and other cities. As a landscape painter, Lessing occupies an important place, being the chief master of the Romantic school in Germany. His landscapes were chiefly wild and solemn mountain scenery, preferably effects of storm or moonlight, painted directly from nature, only the figures being reminiscent of romanticism. Consult Wilhelm Jordan, *Ausstellung der Werke Karl Friedrich Lessings* (Berlin, 1880).

LES′SON (OF., Fr. *leçon,* It. *lezione,* from Lat. *lectio,* reading, lesson, from *legere,* to read, Gk. *λέγειν, legein,* to say). In the liturgical sense, a portion of the Church service appointed to be read, chiefly with a view to instruction and exhortation, as distinguished from prayer and praise addressed to God. In this sense it includes the epistle and gospel (qq.v.), but the term is more commonly applied to the selections read in the ancient breviary office of matins and in the morning and evening prayer of the Anglican churches. The earliest notices we have of services of the first Christians describe them as maintaining this practice and reading from the Old Testament Scriptures. Later, selections from Christian writings were introduced, including the letters of various bishops, especially those of St. Clement and the *Shepherd* of Hermas. Other edifying writings were read. When the canon of Scripture came to be definitely fixed, the reading during divine service was usually restricted to it. At first books were read continuously from beginning to end; but with the gradual development of the liturgical year selections were made in order to have the reading appropriate to the mystery or event commemorated. The arrangement of this order is commonly attributed to St. Jerome.

The lessons in the breviary (q.v.) for matins on Sundays and greater festivals are nine—the first three from Scripture, the next three usually from the lives of the saints or some historical matter, and the last from a homily of one of the fathers on the gospel for the day. On smaller festivals and ordinary week days only three are read. Some monastic rites have four lessons in each nocturn. In the Anglican Prayer Book two lessons, much longer than those in the breviary and of course in English, are appointed for morning and for evening prayer on each Sunday, festival, or week day; the first is always taken from the Old Testament, and the second from the New.

LESSON, lå′sôɴ′, René Primevère (1794–1849). A French naturalist, born at Rochefort. He was largely self-educated, save for a medical course at Rochefort which fitted him for ship's surgeon, and was on board the *Regulus* when it was burned at Bordeaux by the British. He was director of the botanical gardens at Rochefort in 1822, when he was ordered on board the *Coquille* for her famous voyage around the world. After his return he became professor of botany at Rochefort. With Garnot and Guérin he wrote *Voyage autour du monde sur la corvette La Coquille* (1830), and alone published supplements to Buffon (1828, 1835–41), a popular description of the cruise of *La Coquille* (1838), and many works on zoölogy and natural history, especially as relating to medicine.

LESSON IN ANATOMY, or School of Anatomy, The (q.v.). A celebrated painting by Rembrandt.

LES′TER, Charles Edwards (1815–90). An American author, born at Griswold, Conn., a descendant of Jonathan Edwards. He was of a roving disposition and traveled widely in the United States and Europe. He was admitted to the bar in Mississippi and later was ordained a minister in the Presbyterian church. In 1840 he addressed antislavery meetings in Massachusetts and was elected a delegate to the London antislavery conference of that year. He did not return to the United States after the close of the conference, but remained in England. His *The Glory and Shame of England*, published in New York in 1841, criticized England's antislavery professions. In 1842 President Tyler appointed Lester United States Consul at Genoa. He wrote: *The Life of Vespucius* (1845; new ed., 1905); *The Artist, the Merchant, and the Statesman of the Age of the Medici and of Our own Times* (2 vols., 1845); *My Consulship* (2 vols., 1851); *The Napoleon Dynasty* (1852); *America's Advancement, or the Progress of the United States during their First Century* (1878); *The Mexican Republic* (1878); and a *Life of Charles Sumner* (1874).

LES'TERSHIRE. A village in Broome Co., N. Y., on the Susquehanna River, 2 miles west of Binghamton, on the Erie and the Delaware, Lackawanna, and Western railroads (Map: New York, D 6). It has manufactories of boots and shoes, spools and bobbins, cameras, boxes, and furniture. There are also planing mills, etc. The village contains a hospital and owns its water works and sewage system. Pop., 1910, 3775.

LESTOCQ, *le*-stŏk', JEAN HERMANN (1692–1767). A French surgeon and adventurer. He became a surgeon and went to Russia (1713), where he received an appointment in the service of Peter the Great. In 1718, however, he was banished to Kazan on account of his dissolute habits. Recalled by Catharine I (1725), he was appointed surgeon to her daughter, Princess Elizabeth. Lestocq's great influence over Elizabeth was used to encourage her in effecting the revolution of 1741, by which she became Empress of Russia. (See ELIZABETH PETROVNA.) Although at first rewarded handsomely with various state positions, Lestocq, thanks to his enemies, came under suspicion for disloyalty (1748) and was arrested, tortured, and banished to Ustjuk Veliki in the Province of Archangel. He was recalled by Peter III in 1761, and Catharine II gave him a large annual pension and an estate in Livonia.

LESTRANGE, le-strānj', SIR ROGER (1616–1704). An English journalist and translator, born at Hunstanton, Norfolk, Dec. 17, 1616. He was probably educated at Cambridge. Being a zealous Royalist, he accompanied Charles I in his expedition against the Scotch in 1639. In 1644 he was appointed by the King Governor of Lynn, and he attempted to take it from the Parliamentary forces, but, betrayed by two of his accomplices, he was tried, doomed to death as a traitor, and sent to Newgate. After four years he escaped and tried to incite an insurrection in Kent, but, failing, he fled to the Continent. After the passage of the Act of Indemnity (1652) he returned to England (1653) and made personal application to Cromwell and was allowed to remain undisturbed. After the Restoration he was appointed by Charles II censor or licenser of the press. In the *Public Intelligencer*, a newspaper which he started in 1663, he slavishly supported the crown. The *Observator*, begun in 1681, two years after the Popish plot, as the organ of the Tory party, aimed to defend the King from the charge of favoring popery. In 1685 Lestrange was knighted by James II for "his unshaken loyalty to the crown" and elected to Parliament. In 1688 he was deprived of his office of censor and committed to prison for a short time. He died Dec. 11, 1704. In the history of journalism Lestrange occupied a considerable place. His political pamphlets, coarse and brutal in style, hit hard. Among his translations, which have often been praised, are the following: Josephus; Seneca's *Morals* (1693); Erasmus' *Colloquies* (1680); Æsop's *Fables* (1692); Quevedo's *Visions* (1667); Bona's *Guide to Eternity* (1680); *Five Love-Letters from a Nun to a Cavalier* (1678).

LESUEUR, le-sụ'ẽr', CHARLES ALEXANDRE (1778–1857). A French naturalist, born at Havre. He made his first success with his drawings illustrating the zoölogical discoveries of the expedition undertaken by the corvette *La Géographie* when she made her trip around the world (1800–04). With Péron, he published and illustrated valuable monographs on *Radiaires de la classe des méduses* and *Mollusques ptéropodes*. In 1815 he went to America with Maclaure and lived for some time in Philadelphia, where he contributed to the memoirs of the Academy of Natural Sciences. He returned to Havre in 1844 and became keeper of the city's museum.

LE SUEUR, DANIEL (the pseudonym of JEANNE LAPAUZE, née LOISEAU) (1860–1920). A French novelist and poet, who became one of the best known of women writers of her time. In 1904 she married Henry Lapauze, an art critic. Besides having her work crowned by the French Academy, she was awarded the Vitet and other prizes and was appointed Knight of the Legion of Honor. A prolific writer, in later years she published at least one and sometimes two novels annually. Haste and resulting lack of polish characterize this later work. She began with a volume of poems, *Fleurs d'avril* (1882), and wrote also somewhat of country life. Her *L'Evolution féminine* (1905) was written at the request of the Congress of Industry and Commerce of the 1900 Paris Exposition. Among her other works are: *Amour d'aujourd'hui* (1888); *Un mystérieux amour* (1892); *A force d'aimer* (1895); *Invincible charme* (1897); *Au delà de l'amour* (1899); *L'Honneur d'une femme* (1901); *La force du passé* (1905); *Une âme de vingt ans* (1911); *Au tournant des jours* (1912). She also wrote dramas—*Manque d'amour* was played at the Théâtre Sarah Bernhardt.

LE SUEUR, EUSTACHE (1617–55). A French historical painter. He was born in Paris and studied in the atelier of Simon Vouet, where Lebrun was his fellow pupil. One of his early works, "St. Paul Healing the Sick," was painted for the Academy of St. Luke. He was among the first members of the Académie Royale de Peinture et de Sculpture, established in 1648, and the only rival of Lebrun, its founder. During his early years Le Sueur was occupied with miscellaneous designing, but he soon achieved a reputation and was afterward employed constantly in decorative works for Anne of Austria's apartments in the Louvre, for private residences, and for churches. In 1645–48 he executed a series of 22 notable pictures from the life of St. Bruno for the Chartreuse monks in Paris. They are now in the Louvre. Another important work of Le Sueur's, also preserved in the Louvre, was a decoration in the Hôtel Lambert de Thorigny, with mythological subjects representing the "Life of Cupid" and "The Muses." From the purity and grace of his conceptions he was called the French Raphael. In the religious pictures painted by him for Paris churches (10 of which, including "St. Paul at Ephesus" and "The Mass of St. Martin of Tours" are in the Louvre), he shows genuine devotional feeling, but he is never a satisfactory colorist, and is lacking in power. In many of his works he was assisted by his brothers Pierre, Philippe, and Antoine, and his brother-in-law Goussé.

LESUEUR, Jean Baptiste Cicéron (1794–1883). A French architect, born at Clairefontaine (Seine-et-Oise). He was a pupil of Percier, studied at the Ecole des Beaux-Arts, and won the Prix de Rome in 1819. He became a member of the Institute in 1846 and professor at the Ecole in 1852. His principal work, in which he was associated with Godde, was the extension of the Hôtel de Ville of Paris in 1835–54. He also built the Conservatory of Music in Geneva, Switzerland. His publications on architecture include: *Vues des monuments antiques de Rome* (1827), with Alaux; *Architecture italienne ou palais, maisons et autres édifices de l'Italie moderne* (1829), with Callet; *Chronologie des rois d'Egypte* (1848–50), crowned by the Academy.

LE SUEUR, Jean François (1760–1837). A French composer, born at Drucat-Plessiel, near Abbeville. As a child, he was chorister at Abbeville and when 14 was sent to college at Amiens. In 1779 he left there to become music master at the Séez Cathedral and a little later went to Paris, where he was made assistant master at the church of the Innocents. While there he received from the Abbé Roze some musical instruction. In 1781 he accepted the post of music master at the cathedral of Dijon and from there went to Le Mans (1783) and subsequently to Tours. In 1784 he returned to Paris and two years later won in competition the musical directorship of Notre Dame. He inaugurated radical reforms, using a large orchestra and even preluding a mass with an overture. His methods, although popular, aroused bitter opposition, and in 1788 he retired for four years to the country, where he devoted himself to composition. In 1793 he produced in Paris an opera, *La Caverne,* followed the next year by *Paul et Virginie* and *Télémaque.* He was appointed inspector at the Conservatory (1795), but in 1802 lost his position owing to a bitter altercation over the rejection by the Grand Opéra of two of his operas. In 1804 he obtained the highest musical honor in France, being chosen Paisiello's successor as maître de chapelle to Napoleon. His two rejected operas, *Les bardes* and *La mort d'Adam,* were now produced; he succeeded Grétry at the Institute (1813); became superintendent and composer of the chapel of King Louis XVIII and in 1818 professor of composition at the Conservatory. He died in Paris. Le Sueur was a brilliant teacher, and 12 of his pupils (Berlioz was one) won the Prix de Rome. As a composer, he ranked high, his principal characteristics being a grand simplicity and marvelous harmonic skill. He is the earliest exponent of programme music in the modern sense of the term. His hobby was ancient Greek music, and he wrote *Notice sur la mélopée, la rhythmopée et les grands caractères de la musique ancienne* (Paris, 1793). With the exception of the operas already mentioned, his compositions were almost wholly sacred and include the oratorios *Déborah, Rachel, Ruth et Noémi, Ruth et Boaz,* three *Te Deums, Stabat Mater,* masses, etc. Consult Stephen de la Madeleine, *Biographie de J. F. Le Sueur* (Paris, 1841), and Fouqué, *Le Sueur comme prédecesseur de Berlioz* (ib., 1882).

LE SUEUR, William Dawson (1840–1917). A Canadian journalist and author. He was born in Quebec and was educated at the Montreal High School, the Ontario Law School, and Toronto University. In 1856 he entered the Canadian civil service in the Post Office Department, being secretary thereof from 1888 to his retirement in 1902. He was honorary secretary of the Royal Society of Canada (1908–11), vice president of the Peace and Arbitration Society, and vice president of the Canadian Society of Authors. For many years he was an editorial contributor to the Montreal *Gazette,* later to the Montreal *Star,* and also to the leading magazines and reviews of the United States and Canada. He published: *Ste. Beuve; A Defense of Modern Thought; Evolution and the Positive Aspects of Modern Thought; The Poetry of Matthew Arnold; Notes on the Study of Language; The Development of Responsible Government in Canada; The Life of Frontenac* (1906), in the "Makers of Canada Series."

LESZCZYNSKI, lĕsh-chĭn'skė, Stanislas. See Stanislas I Leszczynski.

LETAROUILLY, le-tȧ'ro͞o'yē', Paul Marie (1795–1855). A French architect, born at Coutances. In 1814 he entered the atelier of Charles Percier in Paris and in 1819 entered the Ecole des Beaux-Arts. He spent some time in Italy, then became inspector of construction under the Ministry of Finance, and was chief architect of the Collège de France. He is known chiefly for his *Edifices de Rome moderne* (text, 1 vol., 1868; plates, 3 vols., 1868–74) and *Le Vatican et la basilique de Saint Pierre* (plates, 3 vols., 1882).

L'ÉTAT C'EST MOI, lå'tȧ' så mwä (Fr., I am the state). An expression put into the mouth of Louis XIV and intended to epitomize that monarch's system of absolutism. Various origins are assigned for the phrase. Louis is said to have uttered it in the Parliament of Paris, in 1655, in response to a statement of the President, when he was asked to convoke the States-General, or to a judge who used the words "King and state."

LETCH'ER, John (1813–84). An American politician, Governor of Virginia during the Civil War. He was born in Lexington, Va., was educated at Washington and Randolph-Macon colleges, was admitted to the bar, and began to practice in Lexington, Va., in 1839. In 1850 he was elected a delegate to the Virginia Constitutional Convention and afterward (1851–59) sat in Congress during the stormy times preceding the outbreak of the Civil War. He was Governor of Virginia in 1860–64 and opposed the secession ordinance, but, seeing the hopelessness of maintaining that attitude, turned over the State militia and munitions of war to the Confederate leaders. After the war he was a member of the State Legislature in 1876–77.

LETELLIER DE SAINT JUST, le-tĕl'yā' de säɴ' zhụst, Luc (1820–81). A Canadian statesman. He was born at Rivière Ouelle, Province of Quebec, and was educated to be a notary. Entering politics, in 1851 he was elected a Liberal member of the Canada Legislative Assembly, in 1860 was elected to the Legislative Council, in 1863–64 was Minister of Agriculture in the Macdonald-Dorion administration, and after Confederation was called to the Dominion Senate (1867). He was Minister of Agriculture (1873–76) in the administration of Alexander Mackenzie (q.v.) and in 1876 was appointed Lieutenant Governor of Quebec. His tenure of that office was made notable by the dismissal of the De Boucherville ministry; in 1879 Letellier de St. Just was himself dismissed by the Governor-General-in-Council. (See QUEBEC, *History.*) He died two years later.

LETH'BRIDGE. A city and the capital of Medicine Hat District, Alberta, Canada, on the Canadian Pacific Railway and on the Belly River, 144 miles by rail southeast of Calgary and about 700 miles west by south (direct) of Winnipeg (Map: Alberta, H 9). Among its public buildings and institutions are the courthouse, the customs, land, inland-revenue, and immigration offices, post office, manual-training school, and Y. M. C. A. building. Lethbridge is one of the posts of the Royal Northwest Mounted Police. It is the centre of an irrigation belt of 125,000 acres and the distributing point of southern Alberta and the southeastern British Columbia mining and lumbering districts. In 1915 there were five large coal mines, employing 2000 persons, with a daily capacity of 4000 tons. Its manufacturing establishments include iron foundries and machine shops, brickyards, sash and door factories, flour mills, cigar factories, and a brewery. It is the seat of a Dominion Experimental Farm. The surrounding district is well adapted for mixed farming. The city owns its electric-lighting plant and water works. Pop., 1901, 2072; 1911, 8050; 1915 (local est.), 11,070.

LETHE, lē'thē (Lat., from Gk. Λήθη). The stream of oblivion in the lower world, from which, according to the ancient Greek belief, the souls of the departed drank, to lose all recollection of earthly existence, before passing into the Elysian Fields (q.v.).

LETH'INGTON, LORD. See MAITLAND, SIR RICHARD.

LE'TO. See LATONA.

LETRONNE, le-trôn', JEAN ANTOINE (1787–1848). A French archæologist and historian. He was born and was educated in Paris; traveled in France, Italy, Switzerland, and Holland (1810–12); and for his *Essai sur la topographie de Syracuse* (1813), intended to throw light on the account given by Thucydides (q.v.) of the Athenian attack on Syracuse, and *Recherches sur les fragments d'Héron d'Alexandrie* (written in 1816 and printed 1851), was elected to the Academy of Inscriptions. He became professor of history in the Collège de France in 1831, head of the Royal Library in the same year, professor of archæology at the Collège de France in 1838, and in 1840 inspector general of the national archives. His most important work was *Recueil des inscriptions grecques et latines de l'Egypte* (2 vols., 1842–48, completed by Brunet de Presle). His other works on archæology, especially inscriptions and numismatics, include: *La peinture murale chez les Grecs et les Romains* (1835–37); *Considérations générales sur l'évaluation des monnaies grecques et romaines, etc.* (1817); *Recherches pour servir à l'histoire d'Egypte pendant la domination des Grecs et des Romains* (1823); *Fragments de Scymnus de Chio et du faux Dicéarque* (1840); and, on history, *Matériaux pour servir à l'histoire du christianisme* (1833). Consult J. E. Sandys, *A History of Classical Scholarship*, vol. iii (Cambridge, 1908).

LETTE, lĕ'te, WILHELM ADOLF (1799–1868). A Prussian politician and economic reformer, born in Kienitz. He studied law and philosophy at the universities of Heidelberg, Göttingen, and Berlin. Participation in "demagogic" disturbances resulted in his imprisonment and exclusion from state employ, but neither was of long duration. In 1835 he was connected with the Court of Appeals at Posen, in 1840 was made director of the Prussian Agricultural Bureau at Frankfort-on-the-Oder, and three years later received the appointment of counselor to the Ministry of Interior for agricultural matters. In 1845 he became president of the Court of Errors for agricultural affairs. His interest in the welfare of the people was shown by his establishing many associations; e.g., the Centralverein für das Wohl der arbeitenden Classen and the Berliner Handwerkerverein. In 1848 he was a member of the Constitutional party. In 1851 he was a member of the first Prussian Chamber and a year afterward took a seat in the other House, which he kept until his death. His more important writings are *Die Landeskulturgesetzgebung des preussischen Staats*, with Rönne (1853–54), and *Die Verteilung des Grundeigentums im zusammenhang mit der Geschichte, der Gesetzgebung und den Volkszuständen* (1858).

LETTENHOVE. See KERVYN DE LETTENHOVE.

LETTER (OF., Fr. *lettre*, from Lat. *littera*, *litera*, letter). In law, an authoritative writing empowering the person to whom it is issued to exercise a certain office, perform a duty, or do any other act which, but for such authorization, could not have been lawfully performed. Letters are issued for many purposes and under a great variety of circumstances. A *letter of attorney*, or power of attorney, is a writing or deed authorizing a person to do any lawful act, as to receive and receipt for money, execute a deed or contract, in the stead of the party executing it. *Letter of exculpation*, in Scots criminal law, is a warrant obtained by a prisoner to summon witnesses on his behalf at his trial. *Letter missive*, in England, is an order from the Lord Chancellor to a peer requesting the latter to enter an appearance to a bill filed in chancery against such peer; in Scotland the word means any written agreement or memorandum relative to some bargain as to mercantile matters, or as to the sale of land or houses or the letting of land. *Letter of request*, in English ecclesiastical law, signifies a writ by which a suit against a clergyman is instituted in the Court of Arches, instead of proceeding, in the first instance, in the consistory court. *Letter of safe-conduct* means a writ, under the great seal, to the subject of a state at war with any country, authorizing and protecting such subject, while dealing or traveling in that country, so that neither he nor his goods may be seized, as they otherwise might be. *Letters testamentary* is an instrument issued by a judge who has jurisdiction of probate matters, declaring that a certain will has been admitted to probate and giving the executor power to administer the estate. Such an instrument granted to the administrator of a person dying intestate is called *letters of administration.* See Letters Patent; Letters Rogatory; Credit, Letter of; Administration; Executor; Attorney, Power of.

LETTER CARRIERS, National Association of. An association organized at Milwaukee in 1899 and subsequently incorporated under the laws of Tennessee, with the object of uniting all the letter carriers of the United States in a fraternal society and establishing the Letter Carriers' Mutual Benefit Association and the Letter Carriers' Retirement Association. Its enrolled membership in 1915 was 32,851, out of a total of 36,000 city letter carriers in the United States. There is a similar and separate organization for rural postal carriers. The Mutual Benefit Association, paying insurance benefits, and the Retirement Association, providing for annuities and weekly disability benefits, are subsidiary societies to the National Association. The number of members holding certificates in the Mutual Benefit Association was (Sept. 1, 1914) 6999. The official organ is *The Postal Record,* published at Washington, D. C. The organization has been active politically in securing more favorable working conditions for postal carriers and clerks, in removing the paid service from the influence of party politics, and in agitating for a national pension for superannuated carriers.

LETTER OF ATTORNEY. See Attorney.

LETTER OF CREDIT. See Credit, Letter of.

LETTERS. The characters of written speech. Letters are therefore the components of the alphabet (q.v.). They are quite inadequate to represent the sounds for which they stand, although there have been repeated attempts to make a system of letters which would answer the requirements of phonetics (q.v.). In these so-called phonetic alphabets, as well as in the transcription of alphabets which differ in a marked degree from the Roman script, as Russian, Armenian, Hebrew, Chinese, and many others, it is both customary and necessary to associate various diacritical marks with the Roman letters to approximate their phonetic value in the foreign alphabets in question.

LETTERS, Proportionate Use of. The following tables represent the conclusions based on the experience of printers, with regard to the relative frequency of use of the letters of the alphabet in English composition. The first table exhibits the general use:

E	1,000	M	272
T	770	F	236
A	728	W	190
I	704	Y	184
S	680	P	168
O	672	G	168
N	670	V	158
H	540	B	120
R	528	K	88
D	392	J	55
L	360	Q	50
U	296	X	46
C	280	Z	22

The proportion of their use as initial letters is as follows:

S	1,194	M	430
C	937	F	388
P	804	I	377
A	574	E	340
T	571	H	308
D	505	L	298
B	463	R	291
W	282	J	69
G	266	Q	58
U	228	K	47
O	206	Y	23
V	172	Z	18
N	153	X	4

LETTERS IN LITERATURE. The letter belongs to the most personal branches of literature, represented also by the journal and the confession. For Greek letter writing, see Papyrus Letters.

Of the Roman letters that have survived from antiquity, those of Cicero to Atticus and other friends make the widest appeal. Covering, as they do, the great civil war between Pompey and Cæsar, they are precious historical documents. Cicero himself is always present in his hopes and perplexities; and withal there is a sane reflection on conduct and the course of public affairs. It is perhaps not too much to say that the letter as a literary species, with its own style and form, dates from Cicero. After Cicero the next most notable collection, in order of time, is the series of 124 letters from Seneca to Lucilius. Seneca's letters are, however, rather moral observations and aphorisms put into epistolary form. The letters of the younger Pliny likewise rank high as literature. Besides details in the life of the rich and genial author, they also contain interesting facts concerning the treatment of Christians. Among later Roman letter writers whose work has great historical if not literary interest, were Symmachus and Cassiodorus. From the Romans comes, too, the verse epistle, in which the poet addresses his patron or friend on private or public events, often with a satirical intent. Of this art Horace was the ancient master.

The early fathers of the Church left a large body of theological correspondence. Particularly prized are the letters of Gregory Nazianzen, Basil, Chrysostom, Ambrose, Augustine, Jerome, Zosimus, Leo I, and Gregory I. In the letters of Héloïse to Abélard (twelfth century) there was displayed an intense love passion, the counterpart in real life of the great romance of *Tristan and Iseult.* All through the Renaissance period, when classical ideals played havoc with mediæval notions, letters in Latin were numerous. For Italy there are the famous epistles of Dante and Petrarch; and for Germany, the theological and controversial epistles of Reuchlin, Melanchthon, Erasmus, and Pipsius. A most remarkable collection is the *Epistolæ Obscurorum Virorum* (2 parts, 1515–17), in which Reuchlin's friends Crotus Rubianus and Ulrich von Hutten satirized in comic Latin the ignorance and stupidity of the monks. Though not a very noble defense of classical learning, this vulgar satire was effective in paving the way to a new age.

English literature is extremely rich in letters. At the very threshold of modern times are the *Paston Letters,* which passed between members of a Norfolk family and their friends from the beginning of the reign of Henry VI on into the reign of Henry VII. The correspondence presents a vivid picture of social life at the dawn of the English Renaissance. The Eton boy writes to his "right and reverent and worshipful brother" for money and clothes; and mingled with public and private incidents detailed by the elders are references to Latin manuscripts and translations passing from hand to hand. Less sincere, but of finer literary quality, are the letters of James Howell, published in installments under the title *Epistolæ Ho-elianæ; Familiar Letters* (1645–47–50–55). The best of them, abounding in shrewd observation and humorous anecdote, are written with a graceful pen. Long considered genuine, it now seems that they were mostly literary exercises put into epistolary form. Howell's success led at once to fictitious collections by Robert Loveday and Margaret, Duchess of Newcastle. By 1740 imaginary letters on a great variety of topics were much sought by publishers. It was at this time that Samuel Richardson, when asked to write such a collection, wove into the correspondence the story *Pamela* and thus transformed a bundle of letters into the novel of manners.

In the meantime letters were passing between real men and women. The correspondence between Sir William Temple and Dorothy Osborne, his future wife, records a tender attachment and has a glow and charm of sentiment that should entitle it to a wider vogue than it has ever found. A little later, Temple's amanuensis, afterward Dean Swift, was sending his charming prattle to Stella; but her letters in reply were destroyed by the great Dean. Swift also kept up a correspondence with Arbuthnot, Bolingbroke, and Pope, and wrote those "masterpieces of dreadful humor" called the *Drapier's Letters*. Pope's own correspondence with his friends, presenting the poet as he wished to appear to the world, is a good example of an autobiography in letter form. One of Pope's correspondents was Lady Mary Wortley Montagu, whose letters, covering nearly 50 years, were published after her death. As vivacious comments upon contemporary life, social and literary, they are among the best that have ever come from women. Individual letters of Dr. Johnson, as the repudiation of Lord Chesterfield, are celebrated. Chesterfield's letters to his natural son, forming a cyclopædia of polite manners, created a great stir in their time and are still read for their natural grace and good breeding. In the *Citizen of the World* Goldsmith turned an imaginary correspondence into a light satire of contemporary manners. Many imitators followed down to the time of Robert Southey. The political satire in letter form attained its greatest popularity in the *Letters of Junius* (q.v.). The finest personal letters of the eighteenth century came from Walpole, who wrote with abandon, giving loose rein to anecdote, gossip, scandal, and playful cynicism. Gray's letters, tender, affectionate, and lit here and there with gleams of exquisite humor, are perfect in tone and temper. In style Cowper stands midway. His letters, written without revision or erasure, are the spontaneous expression of a tender and humorous nature softened by melancholy. Among other names of the eighteenth century that should not be forgotten are Addison, Sterne, Frances Burney, Mary Wollstonecraft, Hannah More, and Burns.

During the last century the literature of letters became vast. The death of any author of repute is now sure to be followed by the publication of his correspondence, which serves as an autobiography for the whole or a part of his career. Particularly interesting was the fairly successful attempt to tell the story of George Eliot's life by a chronological arrangement of her letters with slight connecting links from the pen of her husband. Of genuine letters addressed from friend to friend, the choicest since Cowper are by Byron and Charles Lamb. The letters of Edward FitzGerald, addressed to some of the most eminent men of his time, are also models of ease and frankness. Public curiosity has led to the publication of the love letters of literary men. The two most notable examples are the letters of Keats to Fanny Brawne and the correspondence between Browning and Miss Barrett just before their marriage. Great interest also attaches to the correspondence of Scott, Southey, De Quincey, Leigh Hunt, Sydney Smith, Lockhart Hood, Macaulay, Emerson, Carlyle, Mrs. Carlyle, Thackeray, Ruskin, Matthew Arnold, Stevenson, Lowell, and T. E. Brown.

It has generally been conceded that the French excel all other nations in the art of letter writing. And certainly, if one were called upon to select the most charming letter writer of modern times, the lot would fall to Madame de Sévigné, a member of the celebrated Hôtel de Rambouillet. She was a part of the best Parisian society for more than 40 years. Her daughter married the Count de Grignan and settled in Provence. This separation was the occasion of the famous correspondence, never intended for publication, describing with extraordinary art and *esprit* the life of the capital. To the same period belong the letters of Madame de Maintenon, Guy Patin, and Racine. The theological letter received its highest style from Pascal in the *Lettres à un provincial*. For the eighteenth century may be cited Madame du Deffand; Voltaire, who left many volumes of correspondence, including letters from England and letters to Frederick the Great; and Rousseau, who, besides numerous letters to his friends, wrote a novel in letter form. The classic traditions of the French letter were continued by Madame de Staël, Hugo, Sainte-Beuve, George Sand, Alfred de Musset, the Goncourts, and Prosper Mérimée, whose intimate *Lettres à une inconnue* appeared after his death.

German letters do not impress a foreigner with those prime requisites to a good letter—ease and grace. On the other hand, the German usually has something worth saying. Best known outside of Germany are the letters of Luther to his friends and family, the correspondence between Goethe and Schiller, and the letters of Bismarck to his wife. No letters equal those between Goethe and Schiller for letting one into the secrets of great authorship. Each informs the other of what he is doing and, so far as he can, describes the method of procedure. Schiller's letters to Körner treat in part the same theme. Among other Germans who have left valuable letters are Lessing, Herder, Winckelmann, the brothers Humboldt, Richter, the Schlegels, Heine, the Grimms, and Richard Wagner.

Bibliography. Roberts, *History of Letter-Writing from the Earliest Period to the Fifth Century* (London, 1843); Holcombe, *Literature in Letters* (New York, 1866); Knight, *Half-Hours with the Best Letter-Writers* (London, 1867); some interesting comments on ancient Egyptian letter writing on papyrus in W. Pleyte, *L'Epistolographie égyptienne* (Leyden, 1869); Scoones, *Four Centuries of English Letters* (ib., 1880); *Great English Letter-Writers* (2 vols., New York, 1909), edited by W. J. and C. W. Dawson, an excellent anthology of English letters, introduced by a study of the development of English letter writing.

LETTERS OF JUNIUS. See JUNIUS, LETTERS OF.

LETTERS OF MARQUE. See MARQUE, LETTERS OF.

LETTERS PATENT. An open letter under the seal of the government granting some property, right, privilege, or title. It is in form an open letter addressed to the public and intended to be evidence of the rights of its grantee. The term is usually now applied to (*a*) an instrument issued from the Patent Office in the name of the government, granting and confirming to an inventor the exclusive right and privilege to his invention; (*b*) less specifically, an instrument by which lands are granted by the government to individuals. See PATENT; PATENT LAW.

LETTERS ROGATORY. A written instrument addressed by one court to another in a foreign jurisdiction, requesting the latter to cause to be examined, upon written interrogatories annexed, a witness who is within the jurisdiction of the latter court. Letters rogatory are designed to accomplish the same purpose as a commission to take depositions. Letters rogatory are sent to foreign countries, as there is no "comity of states" to rely on in such cases, and are quite common, especially in Admiralty proceedings. See DEPOSITION.

LETTERS TO DEAD AUTHORS. A series of critical essays by Andrew Lang (1886).

LET′TERWOOD, or SNAKEWOOD. The heartwood of a rather rare British Guiana tree, *Brosimum aubletti*, of the family Moraceæ. It grows from 60 to 70 feet high and acquires a diameter of from 2 to 3 feet. The sapwood is white and hard; the harder and heavier heartwood, which rarely exceeds 7 inches in thickness, is a rich brown, beautifully mottled with deeper shades of brown, almost black, spots, arranged with much greater regularity than is usually the case in the markings of wood and bearing a slight resemblance to the thick letters of some old black-letter printing. In Guiana it is used for small articles of cabinetwork and elsewhere only for fine veneer and inlaying work.

LET′TIC LANGUAGE AND LITERATURE. The language and literature of the Letts (q.v.), living in the Russian Province of Courland, Livonia, Vitebsk, Kovno, and Pskov, and in East Prussia and in the United States and Brazil. The number of Lettic-speaking people is estimated at 2,000,000. With Lithuanian (q.v.) and Old Prussian (q.v.), Lettic forms the Baltic subdivision of the Indo-Germanic languages (q.v.). The mutual relation between Lettic and Lithuanian is approximately the same as between Old High German and Gothic. Only in a few points is Lettic the more archaic. It has preserved unchanged Indo-Germanic *s* and *z* where Lithuanian has modified them into *sz* (*sh*) and *ž*, and it retains the original short vowels where Lithuanian shows long vowels of later development. The imperative is identical with the second person indicative, while Lithuanian has developed a new form with *k* as the characteristic sign. On the other hand, Lettic has lost the pure *o* sound and has lost the nasal *n* (as, Lith. *rankà*, OChurch Slav. *rąka*, Lettic *ruka*, Russ. *růka*, hand; Lith. *linkti*, Lettic *likt*, to bend). Usually the vowels in final syllables are dropped (as, Lettic *růkás*, Lith. *rañkosu*, locative pl. of *rankà*, hand, Lettic *likt*, Lith. *linkti*, to bend). Morphologically Lettic, like the Romance languages, possesses only two genders, the neuter (in pronouns and adjectives) being replaced by the masculine. The dual has disappeared entirely, except in *diwi*, two, and *abbi*, both. Of the eight Indo-Germanic cases, the ablative is lost, and the nominative generally performs the functions of the vocative, while the instrumental is usually identical with the accusative in the singular and with the dative in the plural. The verb, which is divided into 12 classes, has only three simple tenses (present, preterite, and future) and three simple moods (indicative, conditional, and imperative), besides an infinitive stem and a supine in *tu*. It has an active and a reflexive, formed by adding *-s* = *sewi*, self, as well as a passive voice, and six participles, four active (two present, one preterite, and one future) and two passive (present and preterite). The number of periphrastic forms is extremely large. As in Czech, the accent came to be fixed invariably on the first syllable. In its vocabulary Lettic exhibits the influence of German, Russian, Esthonian, Livonian, Finnish, and Scandinavian, and three groups of dialects are distinguished: High Lettic, in the east; Low Lettic, or Tahmian, in northwestern Courland; and Middle Lettic, on which the literary language is based.

The earliest printed literary monuments in Lettic are a translation of Luther's *Catechism* (printed in Königsberg, 1586), *Undeutsche Psalmen*, and *Gesänge* (ib., 1587), a Lettic version of psalms and hymns. A Lettic Bible was printed at Riga (1685–89). A special alphabet based on the German was created by Manzelius (1593–1654). Nearly all the works up to the time of G. F. Stender (1714–96) were of a religious character. Stender compiled an exhaustive dictionary and wrote a grammar which marked an epoch in the history of Lettic. He also composed stories and tales, and a *Book of Wisdom Concerning the Universe and Nature* (*Augstas gudribas grahmata*, 1776), containing elements of astronomy, geography, and history, as well as odes and songs. His son Alexander (1744–1819) wrote the first Lettic comedy. The period 1750–1820 is marked by the birth of national consciousness. The educational efforts of the pastors J. C. Wolter (1799–1856) and Watson were largely instrumental in spreading among the hitherto neglected lower classes the elements of a national culture. To promote it further, periodicals were started, of which the *Latweeschu Awise*, founded by Watson in 1822, was the first, and the *Magazin*, the organ of the Lettic Literary Association of Mitau since 1827, has been the most important. The decades 1860–80 were the culminating years of this nationalism in literature, with Woldemar at the head of the "Young Lettic" group, mostly educated in Russian universities. They endeavored to rid themselves of the all-pervading German influences; they translated the European and Russian classics and published periodicals wherein the whole economic, social, and intellectual life of the Letts was discussed with a view to betterment. The last two decades of the nineteenth century were characterized by striving to gain independence from foreign ideals. The best authors of the period were Jur Allunan, a lyric poet and editor of the almanac *Home, Nature, and Universe;* Kroghen (pseud. Ausaklis); the brothers Kaudsit; the Nationalist Kronwald; Neikens; Pumpurs; the folklore collector Treuland-Brihwsemneeks; and the lyric poet Lautenbach (pseud. Jųsminis, professor at Dorpat). The best-known modern names are the poetess Rosenberg-Aspasia; Ap-sit; Blauman; Steperman, the author of historical dramas; the lyric poet Rainis-Pleekschau, author of an admirable translation of *Faust;* the critics Theodor, Janson, and Zeifert; and the fertile Martin Lap, a ballad writer and translator of great gifts. In 1896 the works existing in Lettic numbered 2027, besides 10 periodicals. The Lettic folk literature is enormous, especially in the line of proverbs, riddles, tales, legends, and songs (*dainas*).

Bibliography. Bielenstein, *Die lettische Sprache* (Berlin, 1863–64); id., *Lettische Grammatik* (Mitau, 1863); id., *Die Elemente der lettischen Sprache* (ib., 1866), popular in treatment; Ulmann and Brasche, *Lettisches Wörterbuch* (Riga, 1872–80); Bielenstein, *Tausend lettische Räthsel, übersetzt und erklärt* (Mittau, 1881); Bezzenberger, *Lettische Dialekt-Studien* (Göttingen, 1885); id., *Ueber die Sprache der preussischen Letten* (ib., 1888); Thomsen, *Beröringer melem de Finske og de Baltiske Sprog* (Copenhagen, 1890); Bielenstein, *Grenzen des lettischen Volksstammes und der lettischen Sprache* (St. Petersburg, 1892); Baron and Wissendorff, *Latwju dainas* (Lettic Folksongs, Mitau, 1894); Andreianov, *Lettische Volkslieder und Mythen* (Halle, 1896); Bielenstein, *Ein glückliches Leben* (Riga, 1904); Brentano, *Lehrbuch der lettischen Sprache* (Vienna, c.1907); Wolter, "Die lettische Literatur," in *Die ost-europäische Literaturen* (Berlin, 1908); Kalning, *Kurzer Lettischer Sprachführer* (Riga, 1910). Among the latest literary histories in Lettic may be mentioned: Klaushush, *Latweeschu vakstneezibas wehsture* (Riga, 1907); Pludons, *Latwiju literaturas vēsture* (Jelgava, 1908–09); Lehgolnis, *Latweeschu literaturas wehsture* (Riga, 1908).

LETTRES DE CACHET, lĕ'tr' de kȧ'shȧ' (Fr., letters of seal). The name given to the warrants of imprisonment issued by the kings of France before the Revolution and used to imprison people of high birth for political and social reasons often of a private nature. They were written on ordinary paper, signed by the King and countersigned by one of the secretaries of state and sealed with the King's little seal (cachet). They differed from the lettres patentes, or formal letters of authorization, which were open, signed by the King, countersigned by a minister, and bore the great seal of state. Lettres patentes required to be registered by the parlements; but lettres de cachet, as the expression of the King's will in matters presumably private, were exempt from the jurisdiction of the parlements. By the lettres de cachet the royal pleasure was made known to individuals or to corporations, and the administration of justice was often interfered with. The use of lettres de cachet began in the fourteenth century, but became especially frequent after the accession of Louis XIV. It was very common for persons to be arrested upon such warrants and confined in the Bastille (q.v.), or some other state prison, where many of them remained for a very long time, and some for life, either because it was so intended or in other cases because they were forgotten. These warrants were used by the King and those who had sufficient influence at court to obtain them for the purpose of getting rid of personal enemies and often of relatives whose actions were embarrassing or unpleasant. The lieutenant general of police kept forms of lettres de cachet ready, in which it was only necessary to insert the name of the individual to be arrested. Sometimes an arrest by lettres de cachet was resorted to in order to shield criminals from justice. Lettres de cachet were issued in great numbers after the revocation of the Edict of Nantes (1685) for the purpose of breaking up Protestant households. Their use declined under the Regency, but during the early part of the reign of Louis XV they were employed by the Jesuits as a powerful weapon of persuasion —80,000 lettres de cachet being issued, it is stated, during the ministry of Cardinal Fleury. In the course of time the abuse of the lettres de cachet became notorious. A regular traffic in them was carried on by the King's mistresses, and for the sum of 25 louis d'or any man might rid himself of his enemy with secrecy and expedition. The lettres were often issued *en bloc* without the name of the person to be arrested, the recipient entering names at will. The Parlement frequently protested against the criminal misuse of the lettres de cachet, and their suppression was universally demanded on the eve of the Revolution. They were abolished by the National Assembly, Jan. 15, 1790. Consult: Honoré Mirabeau, *Les lettres de cachet et des prisons d'état* (Hamburg, 1782); Funck-Brentano, *Les lettres de cachet en blanc* (Paris, 1897); André Cassaigne, *Les lettres de cachet sous l'ancien régime* (ib., 1903); Funck-Brentano, *Les lettres de cachet à Paris* (ib., 1904).

LETTRES DE FEMMES, de fȧm (Fr., letters of women). A collection of graceful but often indecent tales by Marcel Prévost (1892), followed in 1894 by *Nouvelles lettres de femmes* and in 1897 by *Dernières lettres de femmes*.

LETTRES DE MON MOULIN, de môɴ mōō'lăɴ' (Fr., Stories from my Mill). A series of stories by Alphonse Daudet (1869), which first appeared in *L'Evénement*.

LETTRES PERSANES, pĕr'sȧn' (Fr., Persian Letters). A criticism and satire on French affairs by Montesquieu, published anonymously at Amsterdam in 1721.

LETTRES PROVINCIALES, prȯ'văɴ'syȧl'. See Pascal, Blaise.

LETTS. A branch of the Letto-Lithuanian group of the Aryan family, living in the Russian governments of Courland, Livonia, Vitebsk, Kovno, and Pskov, and in East Prussia. A number have migrated to the United States and Brazil. They differ little in physical appearance from the Lithuanians, but are less modified by German, Finnish, and other peoples, and they retained some of their pagan customs down into the eighteenth century. The Letts are estimated to number about 1,350,000 to 2,000,000. They are mostly Protestants. See Lettic Language and Literature.

LETTUCE, lĕt'ĭs (OF. *letuce, laitue, letue,* Fr. *laitue,* from Lat. *lactuca,* lettuce, from *lac,* milk), *Lactuca.* A genus of plants belonging to the family Compositæ. The garden lettuce (*Lactuca scariola,* or *Lactuca sativa*) is supposed to be a native of the East Indies, but is not known to exist anywhere in a wild state. From remote antiquity it has been cultivated in Europe as an esculent and particularly as a salad. It has a leafy stem, oblong leaves, a spreading, flat-topped panicle, somewhat resembling a corymb, with yellow flowers, and a fruit without margin. It is now generally cultivated in all parts of the world where the climate admits of it. The many varieties are divided into two groups: cos (or romaine) and cabbage lettuce—the former having the leaves more oblong and upright, requiring to be tied together for blanching; the latter with rounded leaves, which spread out near the ground. Lettuce is generally eaten raw, with vinegar and oil, more rarely as a boiled vegetable. When grown in gardens, the seed is planted in rich, loose soil as early in the spring as the ground can be worked. Market gardeners grow the seedling plants in the greenhouse or hotbed and transplant 8–12 inches apart in the open field after the plants have been well hardened off. The forcing of lettuce in greenhouses has been an important industry in the vicinity of large cities in the northern and eastern United States. In recent years these cities have been partially supplied from the crop grown in Florida and other southern regions during the winter. The other species of this genus exhibit nothing of the bland quality of the garden lettuce. The strong-scented lettuce (*Lactuca virosa*) is distinguished by the prickly keel of the leaves and by a black, smooth seed, with a rather broad margin. The dried milky juice of this species yields lactucarium, used in medicine as a mild anodyne and narcotic.

Lettuce Diseases. Lettuce, especially when forced or grown under glass, is liable to one or two serious fungous troubles. The most serious is known as wilt, rot, or drop, which is due to attacks of *Sclerotinia libertiana.* The presence of the fungus may be noted by a dark-colored decayed spot on the stem near the ground, or the appearance of water-soaked areas on the leaves, which spread, and the whole plant collapses. Since the fungus is a soil growth, steaming the soil before planting in the benches is recommended. A temperature of 175° to 200° is deemed sufficient if continued for an hour or more. Lettuce will grow at a temperature below that required for the development of the fungus—a fact of which advantage may be taken. A gray mold due to *Botrytis cinerea* attacks the leaves, causing wilted patches soon covered by the fruiting bodies of the fungus. Weak plants succumb to the attack. Ventilation, reduction of temperature, and generally better management will reduce losses from this disease. Lettuce is also subject to damping off due to *Corticium vagum solani.* A mildew (*Bremia lactucæ*) attacks lettuce in the same condition as the rot. Care in ventilation will to a great degree control this disease. A rust due to *Puccinia prenanthis* and a leaf spot caused by *Septoria consimilis* sometimes attack lettuce, but aside from temporary disfigurement seldom occasion much loss. See Plate of SALAD PLANTS.

LETTUCE BIRD. The American goldfinch (q.v.).

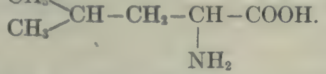
LEUBE, loi′be, WILHELM (1842–). A German physician, specialist in diseases of the digestive organs. He was born at Ulm and studied medicine and chemistry at Tübingen, Zurich, Berlin, and Munich. In 1868 he became clinical assistant at Erlangen, in 1872 professor of pathology and therapeutics and director of the medical clinic at Jena, and in 1885 professor and director of clinic at Würzburg. He retired in 1911. Leube specialized in physiological chemistry; with Rosenthal prepared a "digested food" ("Leubes Fleischsolution"); and wrote: *Ueber die Wirkung des Dünndarmsaftes* (1868); *Ueber die Ernährung vom Mastdarm aus* (1872); *Die Krankheiten des Magens und Darms* (2d ed., 1878); *Behandlung der Urämie* (1883); *Chemie in der Medizin* (1884); *Spezielle Diagnose der innern Krankheiten* (8th ed., 1894–98).

LEUCA′DIA. One of the Ionian Islands. See SANTA MAURA.

LEUCHSENRING, loiK′sen-rĭng, FRANZ MICHAEL (1746–1827). A German man of letters, born at Langenkandel in Alsace. Leuchsenring was a friend of Jacobi, Herder, Goethe, and Wieland for a time, but they all broke with him, and Goethe portrayed him in no flattering colors in his farce *Pater Brey.* He also describes him in *Dichtung und Wahrheit.* He was a sentimentalist, a member of the Illuminatenorden, and continually suggested among his friends the foundation of a secret order of sentimentality. Consult J. W. von Goethe, *Dichtung und Wahrheit,* book xiii; also *Briefe an und von Merck;* Varnhagen von Ense, *Vermischte Schriften,* vol. iv (Mannheim, 1838).

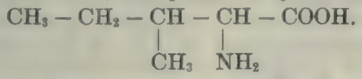
LEUCHTENBERG, loiK′ten-bĕrK. See BEAUHARNAIS.

LEUCINE, lū′sĭn (from Gk. λευκός, *leukos,* white; connected with Lat. *lux,* light, OIr. *lóche,* lightning, OChurch Slav. *luča,* ray, Skt. *ruc,* to shine, OHG. *lioht,* Ger. *Licht,* AS. *lēoht,* Eng. *light*), or AMINO-CAPROIC ACID, $C_6H_{13}NO_2$. A name applied to four isomeric acids, of which three, viz., levo-leucine, dextro-iso-leucine, and normal leucine, exist chemically combined in the proteins and are, therefore, substances of importance. The most commonly found of these isomers is levo-leucine, which also occurs in the uncombined state in the animal body. It crystallizes in white (whence the name leucine) leaflike crystals that melt at 280° and are moderately soluble in water. Its aqueous solution (in the absence of alkalies) turns the plane of polarized light to the left (whence the prefix "levo"). Prolonged heating in barium hydroxide solution transforms half of the levorotatory into the dextrorotatory modification, the resulting mixture, of course, being optically inactive. This inactive, or racemic, mixture is attacked by green mold (*Penicillium glaucum*), the levo-modification being destroyed much more rapidly than the dextro, so that it is possible to obtain the dextro-modification (which does not occur in nature) practically free from the antipodal modification. The constitution of either levo- or dextro-leucine is represented by the formula:



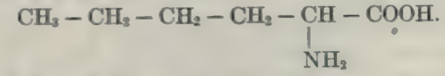
Inactive or racemic leucine (i.e., a mixture of the dextro- and levo-modifications) has also been obtained by several different synthetic methods.

Dextro-iso-leucine, as shown by Ehrlich and Wendell in 1908, probably always accompanies levo-leucine among the degradation products of the proteins. It is fairly soluble in cold water and the solution rotates the plane of polarized light to the right. Prolonged heating with barium hydroxide turns it into a racemic mixture, which is optically inactive. The constitution of iso-leucine (whether the dextro- or the levo-modification) is represented by the formula:



$$CH_3 - CH_2 - \underset{\displaystyle CH_3}{\underset{|}{CH}} - \underset{\displaystyle NH_2}{\underset{|}{CH}} - COOH.$$

Normal leucine, the third important modification of leucine, probably occurs chemically combined in casein. Its two optical isomers, the dextrorotatory and the levorotatory, as well as the racemic (inactive) form, are known. The chemical constitution of normal leucine is represented by the formula:



$$CH_3 - CH_2 - CH_2 - CH_2 - \underset{NH_2}{\underset{|}{CH}} - COOH.$$

LEUCIP'PUS (Lat., from Gk. Λεύκιππος, *Leukippos*). The founder of the atomistic school of Greek philosophy and forerunner, by some 40 years, of Democritus (q.v.). Nothing is known of his life. Consult: Lortzing, in Conrad Bursian (ed.), *Biographisches Jahrbuch für Alterthumskunde*, vol. cxvi (Berlin, 1904); Theodor Gomperz, *Greek Thinkers*, vol. i (Eng. trans., New York, 1905); John Burnet, *Early Greek Philosophy* (2d ed., ib., 1908).

LEUCITE, lū'sīt (from Gk. λευκός, *leukos*, white). An aluminium and potassium silicate, dimorphous in crystallization, being isometric only above a temperature of 500° C. It is translucent to opaque, with a vitreous lustre and a smoky-gray color. Leucite occurs chiefly in volcanic formations, and the best-known localities are Vesuvius and Mount Somma in Italy, where it is disseminated in grains through the lava: also in the United States at various localities in Wyoming. Millstones of this leucite lava have been found in the excavations at Pompeii. The white varieties are called *white garnet*, owing to their resemblance to the trapezohedral crystals of garnet.

LEUCKART, loi'kärt, RUDOLF (1822–98). A German zoölogist, born in Helmstedt. He studied at Göttingen and, after teaching a few years there, became, in 1850, professor of zoölogy at Giessen; and at Leipzig in 1870. His earliest contributions to zoölogy were epoch-making in that he divided Cuvier's type Radiata into Echinodermata and Cœlenterata and grouped the remainder of the animal kingdom under the four heads of Vermes, Arthropoda, Mollusca, and Vertebrata—a classification which in the main holds at the present time. He published on a wide variety of subjects, but during the latter half of his life devoted himself almost exclusively to the study of parasitic worms and became the greatest authority of his time on them. Of his numerous publications, the following are important: *Beiträge zur Kenntnis der wirbellosen Thiere* (1847, with H. Frey); *Ueber Morphologie und Verwandtschaftsverhältnisse der wirbellosen Thiere* (1848); *Ueber den Polymorphismus der Individuen oder die Erscheinungen der Arbeitsteilung in der Natur* (1851); *Ueber die Mikropyle und den feineren Bau der Schleimhaut bei den Insecteneiern* (1885); *Die Blasenbandwürmer und ihre Entwickelung* (1856); *Untersuchungen über Trichina Spiralis* (1860; 2d ed., 1866); *Die Parasiten des Menschen* (2 vols., 1863–76; 2d ed., 1879–89; Eng. trans., *The Parasites of Man*, 1886); *Zoologische Wandtafeln* (1877–98).

LEU'COCYTE (from Gk. λευκός, *leukos*, white + κύτος, *kytos*, cell). A lymphoid or amœboid cell. The name is generally applied to lymph cells outside the blood vessels and to the white corpuscles of the blood (q.v.). The source of the white cells of the blood is undoubtedly the lymphatic glands as well as the bone marrow, the spleen, and the gastrointestinal lymph follicles. See BLOOD.

LEU'COCYTHÆ'MIA (Neo-Lat., from Gk. λευκός, *leukos*, white + κύτος, *kytos*, cell + αἷμα, *haima*, blood); also known as leukæmia. A disease characterized by a great increase in the number of white corpuscles in the blood, together with changes in the bone marrow, spleen, and lymphatic glands. The disease was first noted in 1841 by Bennett, of Edinburgh, who considered the affection due to the presence of pus in the blood and gave it its name. In the same year Virchow, of Würzburg, published his observations upon the disease and was the first accurately to recognize and describe it. He gave it the name "leukæmia." Virchow's theory of the pathogenesis has been adopted, viz., that it is primarily a disease of the blood-making organs, and that the conditions of the blood are secondary. The disease is common among the working classes, and the majority of the cases occur between the twentieth and fiftieth years. It is twice as common among men as among women. Malaria syphilis, and traumatism are supposed to have an influence as predisposing causes; but there is great reason to believe that the disease is essentially infectious in its nature. The symptoms of the disease are pallor, or an ashen color; palpitation of the heart; dyspnœa upon exertion; enlargement of the lymphatic glands, in bunches, most frequently in the neck; great enlargement of the spleen, with tenderness in the splenic region; enlargement of the liver; diarrhœa; nervous disturbances, including headache, languor, depression, delirium, or even mania; a tendency to hemorrhage; deafness, and vertigo. Two varieties of the disease were first definitely recognized by Ehrlich in 1883, but there are many atypical cases. An examination of the blood will readily determine the presence of the disease and will decide whether the case in hand is of the myelogenous or the lymphatic variety. In the former, which is the more frequent form, there is an excess of the large mononuclear cells, especially of the myelocytes; and also large numbers of nucleated red corpuscles, notably of megaloblasts. In the lymphatic variety there is an unusual proportion of lymphocytes of the ordinary type, or rather large, with paler nuclei and almost wholly without granules; while myelocytes and nucleated red corpuscles are present in very small numbers. Leucocythæmia is almost invariably fatal. The disease may run a course of from five to eight years, though the average duration is less than three years. An unusually rapid form, called by Von Leube *leukanæmia*, is combined with a severe anæmia and ends in death sometimes in a few days. Amelioration of the symptoms may be secured by treatment in some cases. Freedom from care, change of climate, a diet in which carbohydrates and fats are prominent, arsenic, quinine, bone marrow, bitter tonics, and iron are all serviceable. Cold douches to the splenic region as well as faradization or galvanization of this region have relieved the pain or discomfort experienced there. Anorexia, indigestion, constipation, and diarrhœa demand special remedies. The most promising treatment is the employment of the X rays. By this means patients are improved and often kept alive and in comfort for years. As yet no assurance of permanent cure can be given. The enlarged splenic area, and sometimes the liver, the epiphyses of the long bones, and the thorax, are exposed to the radiations. Benzol taken internally has been extolled by some clinicians, but the evidence as to its value is very conflicting.

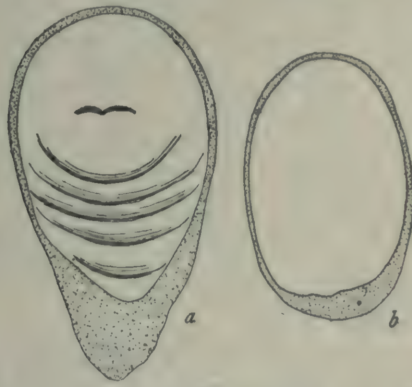
Consult Osler, *On Splenic Anœmia* (New York, 1900); article by Cabot in Osler, *Modern Medicine* (ib., 1914); Naegeli, *Leukaemie und Pseudoleukaemie* (Vienna, 1913).

LEUCO′JUM. See Plate of MOUNTAIN PLANTS.

LEUCOLINE, lū′kō-lĭn. See QUINOLINE.

LEUCO′MA (Neo-Lat., from Gk. λεύκωμα, *leukōma*, white spot in the eye, from λευκοῦν, *leukoun*, to whiten, from λευκός, *leukos*, white). The term applied to a white opacity of the cornea. It is also called albugo. It is the result of acute inflammation or ulceration, giving rise to the deposition of coagulable lymph on the surface or between the layers of the cornea. It is sometimes reabsorbed on the cessation of the inflammation, and the cornea recovers its transparency; but in many cases it is persistent and incurable. It may also be the result of previous ulceration or of injury to the cornea. The mildest degree of opacity is known as nebula, and a grade intermediate between this and leucoma as macula. When perforation of the cornea is followed by adhesion of the iris to the resultant scar, the condition is spoken of as adherent leucoma.

LEU′COPLASTS (from Gk. λευκός, *leukos*, white + πλαστός, *plastos*, formed, from πλάσσειν, *plassein*, to form). Minute colorless bodies (also called *Amyloplasts*), whose special function it is to accumulate starch and sometimes proteids into solid granular form. They are special organs of the protoplasm in active plant cells. Similar to these are the plastids, including chromoplasts and chloroplasts (qq.v.). They may occur in any cell, but are mostly readily observed, because most abundant, in cells devoted to storage of reserve food. The starch-forming leucoplasts absorb the dissolved material (sugar?), convert it into starch, and begin to deposit this starch in their interior (see figure). The mature starch grain is usually oval or roundish, rarely irregular. Structurally it is a sphere crystal, being composed of minute hairlike crystals (trichites), which radiate from a centre. Additions to the starch grain, as it is growing, are made exclusively upon its surface. As the starch grain increases in size in the interior of the leucoplast, the latter is stretched. If the grain originates in the centre of the leucoplast, the stretching may be uniform, in which case nearly equal layers may be added to all sides. More often, however, it arises eccentrically, and then the main portion of the leucoplast lies at one side of the starch grain, the smaller portion being stretched until it forms a very thin, almost invisible membrane. In this case the additions to the starch grain will be more rapid on the side where the larger mass of the leucoplast lies. If the leucoplast is ruptured, remaining in contact with only one side of the starch grain, further additions will be confined to portions in contact with the leucoplast (see figure). If a starch grain begins to develop at more than one point, two or more may arise within a single leucoplast, producing the so-called "compound" starch grains. The leucoplast is visible on the larger grains only after special treatment. In some cases leucoplasts accumulate in their interior masses of solid proteids which may or may not take the crystalline form. Such leucoplasts have recently been distinguished by the name "proteinoplasts."



STARCH GRAINS (WHITE) FORMING INSIDE LEUCOPLASTS.

a, an eccentric grain, with the bulk of the leucoplast on one end; *b*, a younger stage of the same.

LEUCOPY′RITE. A silver-white, metallic, sesquiarsenide of iron related to and frequently merging into the diarsenide (lollingite). It occurs with other arsenic ores in Carinthia, in Gunnison Co., Colo., and in Orange Co., N. Y.

LEU′CORRHŒ′A (Neo-Lat., from Gk. λευκός, *leukos*, white + ῥοία, *rhoia*, a flow, from ῥεῖν, *rhein*, to flow), or THE WHITES. A catarrhal discharge from the female generative organs, consisting of mucus or mucus and pus. Leucorrhœa is a symptom of disease of the mucous membrane lining the vagina, or the uterus, or possibly of the Fallopian tubes. Any pathological state which keeps the uterus in a condition of engorgement or of retarded circulation may result in leucorrhœa. It is a very common condition and may be of trivial character. It may be an indication of endometritis or salpingitis. Astringent or antiseptic douches are ordered by the physician if the trouble is simply vaginal. Diseases of the uterine adnexa must be met by appropriate surgical measures. The congestion brought about by a misplaced uterus is often responsible for the phenomenon. In many cases it has latterly been found that colon-bacillus infection keeps up the flow. This is successfully treated by a vaccine prepared from this microörganism.

LEUCOSTICTE, lū′kō-stĭk′tē (Neo-Lat., from Gk. λευκός, *leukos*, white + στικτός, *stiktos*, pricked, spotted, from στίζειν, *stizein*, to prick). The generic name of a group of large fringilline birds which inhabit the higher parts of the mountains of the western United States and are often called "rosy finches" because of the red mixed with the brown of their plumage. Consult: Elliott Coues, *Birds of the Northwest* (Washington, 1874); L. S. Keyser, *Birds of the Rockies* (Chicago, 1902); Dawson and Bowles, *The Birds of Washington* (Seattle, 1909).

LEUCOTH′EA. See INO.

LEUC′TRA (Lat., from Gk. Λεῦκτρα, *Leuktra*). A village of Bœotia in Greece (Map: Greece, Ancient, C 2), famous for the great victory which the Thebans under Epaminondas (q.v.) won here over the Spartan King Cleombrotus (371 B.C.), in consequence of which the Spartan supremacy in Greece, which had existed since the close of the Peloponnesian War (404 B.C.), was broken forever. See GREECE, *Ancient History;* THEBES; SPARTA.

LEUKÆ′MIA. See CHILDREN, DISEASES OF; LEUCOCYTHÆMIA.

LEUKERBAD, loi′kĕr-bät (Fr. *Loèche-les-*

Bains). A watering place in the Canton of Valais, Switzerland, about 10½ miles, by road, north of Leuk (Loèche Ville) (Map: Switzerland, B 2). It is situated near the head of the Devla valley at the entrance to the Gemmi Pass (q.v.), and at an elevation of 4629 feet above sea level. It has about 22 baths, impregnated with lime and having a temperature varying from 88° F. to 124° F. During the season (July to September) the baths are frequented by large numbers of visitors. The village is exposed to avalanches and was destroyed in 1518, 1719, and 1756. A strong embankment now guards it from a repetition of a similar catastrophe. The resident population is about 700. The visitors during the summer season bring the temporary population to about 1500.

LEU′KODER′MIA. See Vitiligo.

LEUMANN, loi′män, Ernst (1859–). A specialist in the philology and antiquities of India. He was born at Berg, near Weinfelden, Switzerland, and received his first training in comparative philology at the Frauenfeld Gymnasium. He completed his education at the universities of Geneva, Zurich, Leipzig, and Berlin, and after a two years' stay at Oxford went to Strassburg, where he taught Sanskrit after 1884, becoming professor in 1897. His works include editions of the *Aupapātika Sūtra*, a Jaina treatise (1883), and *Avaśyaka-Erzählungen* (1897); a translation of *Kathakoça, or Treasury of Stories* (1897); an excellent *Sanskrit-English Dictionary* (1899), in collaboration with Monier-Williams and Cappeler, which was followed by the *Etymologisches Wörterbuch der Sanskrit Sprache,* part i (1907); *Zur Nord-Arischen Sprache und Literatur* (1912); and several papers published in *Zeitschrift der deutschen morgenländischer Gesellschaft.*

LEURET, lẽ′rȧ′, François (1797–1851). A French alienist, born in Nancy. He made a special study of the treatment of the insane and ultimately became director of the asylum at Bicêtre (1829). His works include: *De la fréquence du pouls chez les aliénés* (1832), with Mitivié; *Fragments psychologiques sur la folie* (1834); *Anatomie comparée du système nerveux* (1839–58), completed by Gratiolet; *Du traitement moral de la folie* (1840).

LEUTHEN, loi′ten. A village of Lower Silesia, Prussia, 9 miles west of Breslau, celebrated for the victory won there Dec. 5, 1757, by Frederick the Great, with 34,000 men, over an Austrian army of about 90,000 under Prince Charles of Lorraine. The loss of the Austrians was 10,000 in killed and wounded, 12,000 in prisoners, besides 51 standards and 116 pieces of artillery. The victorious army lost 6500 in killed and wounded. The result was the reconquest of the greater part of Silesia by the Prussians. A monument was erected in 1854. Pop., about 800.

LEUTHOLD, loit′hōlt, Heinrich (1827–79). A German poet, born near Zurich and educated in that city and in Basel. His brief literary activity, mostly in Munich and Frankfort, was brought to an end by insanity, and he died in an asylum near Zurich. He was one of the most gifted members of the Munich group of poets. In collaboration with Geibel, Leuthold translated selected French lyrics (1862). He showed great beauty of form and much depth of thought in his lyrics and the (practically lyric) epic *Penthesilea,* posthumously published (1879). Consult: L. Ganghofer's novel *Die Sünden der Väter* (Stuttgart, 1886); A. W. Ernst, *H. Leuthold, ein Dichterporträt* (2d ed., Hamburg, 1893); id., *Neue Beiträge zu H. Leutholds Dichterporträt* (ib., 1897); Paul Heyse, *Jugenderinnerungen und Bekenntnisse* (5th ed., Berlin, 1912).

LEUTZE, loit′se, Emanuel (1816–68). A German-American historical painter of the Düsseldorf school. He was born in Gemünd, Württemburg, May 24, 1816. His parents came to the United States, settling first in Philadelphia, then at Fredericksburg, Va. He received his first instruction in art from J. A. Smith, a portrait painter, in Philadelphia. In 1840 one of his pictures attracted attention and procured him several orders, which enabled him to go to Düsseldorf, where he studied with Lessing. In 1842 he went to Munich, studying the works of Cornelius and Kaulbach, and the following year he visited Venice and Rome. In 1845 he returned to Düsseldorf and was married, making his home there for 14 years. He devoted himself to American, Spanish, and English historical subjects, especially to the famous series of pictures of the Revolution, of which "Washington Crossing the Delaware" (1851–52, in the Bremen Gallery, with a replica in the Metropolitan Museum, New York) is the finest. In 1859 he returned to the United States; in 1860 he received the commission for the fresco on the staircase of the Capitol at Washington, entitled "Westward the Star of Empire Takes its Way." In 1860 he was elected a member of the National Academy. He died in Washington, D. C., July 18, 1868, leaving several large cartoons for the decoration of the Senate Chamber.

Leutze is more famous for the subjects than for the technical qualities of his paintings. His color is often crude and his drawing academic, yet his composition is good, and his figures show a high power of individualization. The most important works are: "Columbus before the Council of Salamanca" (1841, purchased by the Düsseldorf Art Union); "Columbus in Chains" (1842); "Columbus before the Queen"; "Landing of the Norsemen in America" (Pennsylvania Academy, Philadelphia); "Cromwell's visit to Milton" (Corcoran Gallery, Washington); "The Amazon and her children" (ib.); "The Court of Queen Elizabeth"; "Henry VIII and Anne Boleyn" (1858); "The Iconoclast"; "Washington at Monmouth"; "Washington at the Battle of Monongahela"; "News from Lexington"; "Washington at Princeton"; "Lafayette in Prison at Olmütz Visited by his Relatives" (1861); "Westward Ho"; portraits of Lincoln, Grant, General Burnside, and Worthington Whittredge (Metropolitan Museum).

LEUTZE, Eugene Henry Cozzens (1847–). An American naval officer, born at Düsseldorf, Prussia. He graduated from the United States Naval Academy in 1867 and was promoted through the various grades to captain in 1901 and rear admiral in 1907. He commanded the *Michigan* (1896–97), the *Alert* (1897–98), and the *Monterey* (1898–99); participated in the capture of the city of Manila; had charge of the Navy Yard, Cavite, P. I. (1898–1900); superintended the naval-gun factory at Washington, D. C. (1900–02); and was captain of the new *Maine* (1902–04). He served on the Board of Inspection and Survey (1904–05) and was commandant of the Washington Navy Yard and superintendent of the naval-gun factory (1905–10). Retired by operation of the law in 1909, he continued in active service, being commandant of the New York Navy Yard and station in 1910.

LEVAILLANT, le-vȧ′yäɴ′, FRANÇOIS (1753–1824). A French ornithologist and traveler, born at Paramaribo, Dutch Guiana. From 1781 to 1785 he traveled in South Africa, studying the natives and making collections of the birds and large mammals. His works include: *Voyage dans l'intérieur de l'Afrique* (1790; 2d ed., 1803); *Second voyage dans l'intérieur de l'Afrique* (1796; 2d ed., 1803); *Histoire naturelle des oiseaux d'Afrique* (1796–1812).

LEVANT′ (OF., Fr. *levant*, ML. *levans*, Orient, sunrise, from Lat. *levare*, to raise, from *levis*, light), THE. A name employed throughout the whole of Europe to designate the eastern parts of the Mediterranean Sea and adjacent countries. In a wider sense, it is applied vaguely to the regions eastward from Italy, as far as the Euphrates and the Nile; but more generally is used in a more restricted sense, as including only the coasts of Asia Minor, Syria, and Egypt.

LEVA′RI FA′CIAS (Lat., Do thou cause to be levied). An old common-law writ of execution directed to the sheriff of the county, requiring him to levy on the chattels and the profits of the land of a judgment debtor till satisfaction should be made to the judgment creditor. In England the writ had, by the middle of the eighteenth century, been superseded by the writ of elegit and in 1883, by the Bankruptcy Act, it was abolished as a process for enforcing civil judgments, though it is still employed under certain circumstances to enforce payment of a fine imposed in criminal proceedings. In the United States the process lasted longer, but has now generally been displaced by the ordinary writ of execution. See EXECUTION.

LEVASSEUR, le-vȧ′sẽr′, EMILE (1828–1911). A French political economist and statistician, born Dec. 8, 1828, in Paris. After studying at the Lycée Bonaparte, the Collège Bourbon, and the Ecole Normale Supérieure, he was professor in various lycées until 1868, when he was put in charge of a course at the Collège de France. There he became professor in 1872. He had previously (1868) been elected member of the Academy of Moral and Political Science, of which he was thrice laureate. He was active in promoting international congresses for the discussion of statistical and geographical topics, was one of the founders of the French Society of Commercial Geography, served on many commissions, and was president of various economic societies. His works include: *Le question d'or* (1858); *L'Histoire des classes ouvrières en France* (*avant 1789*, 2 vols., 1859, 2d ed., 1901; *de 1789 à 1870*, 2 vols., 1867, 2d ed., 1904); *Précis d'économie politique* (2 vols., 1863–77; Eng. trans., *Elements of Political Economy*, 1905); *La population française* (3 vols., 1889–92); *La France et ses colonies* (3 vols., 1890–92); *L'Enseignement primaire dans les pays colonises* (1897). Levasseur visited the United States in 1893 for the Columbian Exposition. The fruits of his study of the economic conditions of the United States are embodied in *L'Agriculture aux Etats-Unis* (1894) and *L'Ouvrier americain* (2 vols., 1898; Eng. trans., *The American Workman*, 1900). Later writings include: *Les études sociale sous la Restauration* (1902); *Précis d'économie politique* (1905); *Questions ouvrières et industrielles sous la troisième république* (1907); *Histoire du commerce de la France* (part i, 1911; part ii, 1912). Consult the address delivered on Levasseur's jubilee, *Emile Levasseur, 1828, 1868, 1908* (Paris, 1909).

LEVEE, lĕv′ē̇ *or* lĕ-vē′ (Fr. *levée*, a raising, embankment, from *lever*, to raise, from Lat. *levare*, to raise). The name applied to an embankment constructed along the margin of a river to restrain its waters within the natural channel during floods, and particularly the name given to the flood embankments of the Mississippi River. The so-called dikes of Holland and of various European rivers and the flood embankments of the rivers Danube, Vistula, and Po are examples of levees according to the American usage of that term. The levees of the Mississippi River aggregate over 1200 miles in length and are strung along a stretch of about 1000 miles of river from Cairo to the Mexican Gulf. The construction and maintenance of these levees are in charge of commissions maintained by the various States bordering on the river, and of a similar organization maintained by the United States government and known as the Mississippi River Commission. The Mississippi River Commission did its first work of levee building in 1882, but the various State commissions had begun construction long before that time. As early as 1717 De la Tour, who laid out the city of New Orleans, provided for a levee in front of the city which, however, was not completed until some 10 years later. The government levees are built to standard forms and dimensions varying with the height of the embankment required; roughly described, they are embankments of earth having a broad bottom and narrower top and sloping sides. They are constructed by depositing earth in layers on a foundation cleared of all roots and stumps and thoroughly plowed, and then sodding the top and sides with Bermuda grass at two-foot intervals. After the floods of 1912 and 1913, during which there were numerous failures of levees due to various defects, the Mississippi River Commission undertook the construction of experimental levees in order to determine whether a smaller section levee whose face was protected with concrete deposited from a cement gun and with interlocking sheet piling at the foot of the levee would decrease the protection so as to keep the levee dry during the period of highest flood. Such protection was found most serviceable in the experimental installation and the smaller section was found more economical than the large unprotected levee. For a description of the Mississippi River levees, consult Starling, "The Levees of the Mississippi River," *Engineering News*, vol. xxv, and Copee, "Standard Levee Sections," *Transactions of the American Society of Civil Engineers*, vol. xxxix. An excellent discussion of the levees and other features of flood protection along the Mississippi by engineers familiar with local conditions may be found in vol. xlix, *Journal of the Association of Engineering Societies* (Boston, 1912), while a valuable collection of papers, reports, hearings, and general consideration of the subject, *Floods and Levees of the Mississippi River*, by B. G. Humphreys, member of Congress from Mississippi, was published by the Mississippi River Levee Association of Memphis, Tenn. (Washington, 1914). Consult also current files of leading engineering journals, annual reports of the United States army chief of engineers and of the Mississippi River Commission; and for a concise summary of levee construction, *American*

Civil Engineers Pocket Book (2d ed., New York, 1913). (See Drainage; Embankments.) The article Mississippi River contains a full account of the history and construction of the various improvements on that river, including the system of levees.

LEVEE, lĕ-vē′; Brit. lĕv′ē. In its most general sense, a miscellaneous assemblage of guests, a reception, and often a morning reception; more specifically, the state ceremonial of any sovereign receiving visits from those subjects whose position entitles them to that honor. By the usage of the court of Great Britain, a levee differs from a drawing-room in this respect, that gentlemen only are present (excepting the chief ladies of the court), while at a drawing-room both ladies and gentlemen appear. The name arises from the ceremonial attending the rising of the King of France under Louis XIV and his successors. The *grand lever* was the more public, after the King had been shaved and invested with his wig; the *petit lever*, more intimate, was held immediately after he had been awakened and had said his prayers. Even to this a large number of privileged people were admitted, successively in five classes, comprising not only the royal family, but all kinds of officials, domestic, civil, and military. Under Louis XVI, whose tastes were simple and who rose at seven or eight o'clock, the ceremonial *lever* was usually postponed until half past eleven, thus approximating more nearly to the modern levee.

LEV′EL (OF. *livel*, *liveau*, *liveal*, *nivel*, *niveau*, Fr. *niveau*, Sp. *nivel*, *nivello*, Port. *livel*, *nivel*, It. *livello*, from Lat. *libella*, level, balance, diminutive of *libra*, balance, pound). A name especially used in ore mining and referring to the horizontal excavations made at regular intervals from the shaft (q.v.), and used as a traveling way and for transporting the broken ore to the shaft for hoisting. Levels are usually driven in the ore body or in the footwall parallel with the strike of the ore body and a few feet from it. The distance between levels depends on the mining methods adopted and the size and inclination of the ore body. They are commonly 50 to 150 feet apart, but in some of the very deep mines in South Africa this distance has been increased to 400 feet. When the levels are driven in the footwall crosscuts are driven connecting the level with the ore body. In some regions, such as the anthracite region of Pennsylvania, the term "gangway" is used instead of level, and the main gangway is called the entry.

LEV′ELERS. An ultra-reform party which, under the leadership of John Lilburne, became strong in the army of the Long Parliament, when the army overawed that body, and sent Charles I to Hampton Court in 1647. They determined to level all ranks and establish an equality of titles and estates throughout the Kingdom. Several of the officers belonging to this party were cashiered in 1649; and on the departure of Cromwell for Ireland, at the close of that year, they raised mutinies in various quarters, which were suppressed by Fairfax with bloodshed. One of their works, *The Leveler, or the Principles and Maxims Concerning Government and Religion of those Commonly Called Levelers*, shows that in politics their fundamental principles included: (1) the impartial authority of the law; (2) the legislative power of Parliament; (3) absolute equality before the law; (4) the arming of the people for securing the enforcement of the laws and the protection of their liberties. In religion they claimed: (1) absolute liberty of conscience; (2) freedom for every one to act according to his knowledge, even if this knowledge should be false; (3) the consideration of religion in two aspects—one as the correct understanding of revelation, which is a private affair, the other as its effects manifested in actions, which are subject to the authorities. They condemned all strife on matters of faith and forms of worship. This sect disappeared at the time of the Restoration. Consult S. R. Gardiner, *History of the Great Civil War* (London, 1898). See Agreement of the People.

LEV′ELING. The operation of ascertaining the difference of elevation between any two points on the surface of the earth. Leveling is employed to find the relative elevation of points a considerable distance apart, to obtain the profile of a line to establish a grade, or to determine absolute elevations above any particular point of reference. These points may be more or less intermingled in any piece of work. For convenience of discussion, leveling operations, which play a most important part in surveying, may be broadly classed into common spirit leveling, trigonometrical leveling, and precise spirit leveling. The difference between the first and the third classes lies chiefly in the degree of accuracy with which the work is performed.

Spirit-leveling operations are essentially the same whatever their object may be. For example, suppose it is required to determine the difference in elevation between two distant points. The instruments are the Y level and the level rod, forms of which are described and illustrated in the article Surveying Instruments (q.v.). The rod is set up on the starting point, whose elevation should be known, and the level is placed on its tripod a convenient distance away in the direction of the other point, and where a plain view may be had of the level rod. When the level is adjusted, the levelman takes a reading on the graduated level rod at the starting point and records it in his notebook. The rodman then moves his rod to a point ahead of the level, and the levelman, swinging his telescope with its level around in a horizontal plane, takes another reading, which he likewise records. This reading is called a foresight, in contradistinction to the first reading, which is called a backsight. The levelman then removes his level to a point ahead of the second position of the rod, sets it up, adjusts it, and takes a backsight reading on the rod. This being recorded, the rodman moves to a new position ahead of the level, where he sets up the rod on which the levelman takes a foresight reading, and then moves again to a new position ahead of the rodman. By means of sufficient repetitions of these operations the distance between the two points whose differences in elevation are to be determined is traversed, the last reading being taken with the rod set up on the finishing point.

When the final reading has been taken, a simple calculation in addition and subtraction performed on the recorded readings gives the levelman the result he desires, which is the difference in elevation between the starting and the finishing points.

The starting point is referred to some position whose altitude is definitely known and marked, which is termed a bench mark (q.v.), this in turn being referred to some precise bench or to the seacoast where mean sea level has been fixed after many tidal observations and a datum plane established.

In conducting such a series of readings as has been described, the attempt is always made to make the lengths of the backsight and foresight for each setting of the level as nearly equal as possible, and also to make them as long as possible consistent with clearness of sight.

It is in this way that the profile of the route of a railway line, canal, or highway is determined. Having obtained the natural profile, the engineer in railway or road building has to cut down the irregularities by means of one or more uniform gradients. These he determines first on paper, figuring out the rate of ascent or descent. Supposing that he has determined a grade of 1 foot in 100 feet, then each succeeding intervening point is 1 foot higher or lower, according to direction, than the preceding point. The levelman then reruns his line of levels according to this adopted gradient, and marks on the stake at each intervening point the elevation at which its top is above or below the adopted grade line.

Precise spirit leveling is performed in exactly the same way except that larger and more perfect instruments are employed and more care is taken in making the observations and performing other necessary operations. Furthermore, certain corrections must be applied to the field results, the most important of which are the rod length and rod temperature. As carried on by the United States Coast and Geodetic Survey the method of running a line of precise levels is essentially as follows: The line is always run twice in opposite directions, to furnish a check on the work, and in case of disagreement of the results beyond prescribed limits between additional bench marks, additional runnings may be made. Part of this work consists in the establishment of accurate bench marks for the use of local land surveyors and engineers, and it is stated that for the Coast Survey leveling done since 1899 a maximum discrepancy allowed between two measurements on a section 1.6 kilometers (1 mile) long is 5 millimeters or ⅕ of an inch. For sections of other lengths the discrepancy allowed is made proportional to the square root of the length. A test of the accuracy of this form of leveling is found in the closure of large circuits, 50, 100 or 1000 miles in circumference, where the elevations have been carried from one point continuously in one direction around the circuit, and where the computed elevation for the starting point on closing the circuit should agree with that assumed for it at the start, if there are no errors in the leveling.

By the year 1914 precise leveling had been carried on in the United States, so that there were 85 such circuits varying in circumference from 100 to 4700 miles and extending across the continent. The lines were so interlaced that each line forms a part of two circuits. The greatest error indicated by the closure of the circuit in any one line of the system was 2 millimeters per kilometer, or about ⅛ of an inch per mile, while the average error was .3 millimeter per kilometer, or about $\frac{1}{50}$ of an inch per mile. This was shown in a system which involved nearly 31,000 miles of leveling, participated in by various government engineers, including the corps of engineers of the United States army and other organizations, as well as the Coast and Geodetic Survey. The average closing error of less than 2 millimeters per kilometer has been claimed for the leveling done in recent years by the Coast and Geodetic Survey, which in 1914 had completed over 11,000 miles of precise leveling since its adoption of improved and highly accurate instruments. In this work the average rate of progress was 71 miles per month, each mile being leveled at least twice, once in a forward and once in a backward direction. This work of precise leveling was planned to extend over the United States, so that there would be few points which were not within 100 miles of an accurately determined bench mark.

Trigonometric levelings consist in the determination of the difference of level by vertical angles, measuring the angle of elevation or depression of a distant station, and is usually carried on in connection with triangulation, making use of the theodolite. A sight with the telescope of this instrument may be of very great length in mountainous countries, sometimes exceeding 100 miles. As the distance is known between the object sighted and the station, the difference of elevation between the observer's station and the distant points can readily be computed from the angular measurements made. In trigonometric leveling it is necessary to apply large corrections on account of the refraction of the rays of light coming from the distant point to the observer, an amount that is very variable, being different at different hours of the day, and on different days and in different seasons. As little is known of the laws controlling these changes in refraction, the accuracy of trigonometric leveling is considerably less than that of precise spirit leveling, but by connecting the elevations determined from angular measurements at various points with precise level bench marks it is possible to prevent accumulation of errors and secure greater accuracy for the results of the triangular leveling. Such results are often sufficiently accurate for all purposes except very detailed topography. Several thousand points have thus been determined in various parts of the United States. In fact the officials of the Coast Survey believe that the difference of elevation of two points determined by trigonometric leveling may be correct within 1 or 2 inches to the mile when observations for vertical angles have been made in both directions over the line.

Elevations of different points, as the tops of mountains, are often measured by barometer or by noting the temperature at which water boils. These are not exact methods, and are used only in exploration work. See HYPSOMETRY; ANEROID; BAROMETER.

Bibliography. Breed and Hosmer, *Principles and Practice of Surveying*, vol. ii (New York, 1908); J. B. Johnson, *Theory and Practice of Surveying* (17th ed., ib., 1910); Ingram, *Geodetic Surveying and Adjustment of Observations* (ib., 1911); M. Merriam, *American Civil Engineers' Pocket Book* (2d ed., ib., 1913); United States Coast and Geodetic Survey, *Precise Leveling in the United States* (Washington, 1903, 1907); id., *Hypsometry: Fourth General Adjustment of the Precise Level Net in the United States, and the Resultant Standard Elevations* (ib., 1914); also other publications of the Survey, especially *Annual Reports* (1899, app. 8; 1903, app. 3).

LEVEN, lĕv′′n *or* lē′v′n, LOCH. A picturesque lake in the east of Kinross-shire, Scotland (Map: Scotland, E 3). It is oval in shape, about four miles long and two wide and is 350 feet above sea level. It receives several streams and its waters empty through the Leslie River into the Firth of Forth. It is a famous fishing ground, celebrated for trout. Loch Leven Castle, in which, in 1567, Queen Mary was imprisoned and forced formally to abdicate the throne, and whence she escaped in 1568, is on one of the islets in the lake. Consult Burns-Begg, *History of Lochleven Castle* (Kinross, 1877).

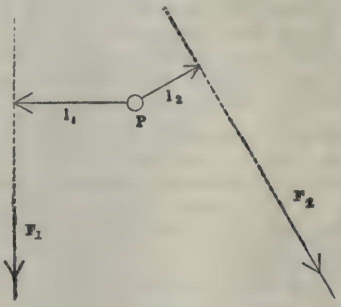
LEVEN, lĕv′en, ALEXANDER LESLIE, first EARL OF (c.1580–1661). A Scottish soldier. He served with Sir Horatio Vere in the Netherlands, and after 1605 under Charles IX and Gustavus Adolphus, kings of Sweden. By 1626 he had attained the rank of lieutenant general under Gustavus, whose fortunes he followed throughout the Thirty Years' War, being present at the battle of Lützen (1632), where Gustavus was killed. In 1636 he succeeded Kniphausen as field marshal in the Swedish army. In 1638–41 Leven was lord general of the Scottish Covenanters in their struggles with Charles I. He was created Earl of Leven in 1641. When the Great Rebellion broke out in England, he commanded the Scottish troops that coöperated with the parliamentarian forces at the siege of York and at Marston Moor. Later when the Scots adopted the cause of Charles II, Leven was placed in chief command; but was defeated by Cromwell at Dunbar in 1650. He was captured by the English in 1651; was imprisoned in the Tower for a short time; was then paroled; and subsequently (1654) he regained full liberty.

LEVENE, le-vēn′, PHŒBUS AARON (THEODOR) (1869–). An American chemist. Born in Russia, he graduated M.D. in 1891 from the Imperial Military Medical Academy, St. Petersburg (now Petrograd), and thereafter studied at the universities of Bern, Marburg, Berlin, and Munich. In 1893 he came to the United States and was a special student at Columbia University. From 1896 to 1905 he served as associate chemist in the New York Pathological Institute, lectured on pathological chemistry at New York University in 1905–06, and was assistant in 1906–07 and chief after 1908 of the department of biological chemistry in the Rockefeller Institute. Levene is author of some 150 monographs, dealing especially with the subject of nutrition, and he contributed to the NEW INTERNATIONAL ENCYCLOPÆDIA.

LEVENSHULME, lēv″nz-hūlm. A manufacturing town in Lancashire, England, 3½ miles southeast of Manchester. Pop., 1901, 11,500; 1911, 19,527.

LÉVÊQUE, lā′vâk′, JEAN CHARLES (1818–1900). A French philosopher, born at Bordeaux. He was a pupil of the Normal School, taught at Besançon, and studied in Athens (1847–48). After his return to France he taught at Toulouse, Besançon, and Nancy. He was appointed to the chair of Latin and Greek philosophy at the Collège de France in 1856 and in 1865 became a member of the Académie des Sciences Morales et Politiques, of which he was vice president in 1873. In philosophy he was a pupil of Cousin. His works include: *Le physique d'Aristote et la science contemporaine* (1860); *La science du beau, ses principes, ses applications, son histoire* (1872); *Études de philosophie grecque et latine* (1864); *Le spiritualisme dans l'art* (1864); *La science de l'invisible* (1865); *Les harmonies providentielles* (1872; 4th ed., 1885).

LEVER, lē′vẽr or lĕv′ẽr (OF. *leveor, leveur,* Fr. *leveur,* lever, from Lat. *levator,* lifter, from *levare,* to raise). A form of machine much used in simple physical instruments. It consists essentially of a rigid body pivoted at one point. If the body is acted on by two forces (F_1 and F_2) in different directions, which hold it in equilibrium, the formula for the mechanical advantage can be deduced at once; the general principle being that since there is equilibrium the moment of one force around the pivot at P, i. e., F_1l_1, must equal the moment of the second force around the same axis, i.e., F_2l_2. The fixed point is called the fulcrum, and l_1 and l_2 the lever arms. Thus, to balance a force F_1 a force F_2 is necessary, where $F_1l_1 = F_2l_2$. The "mechanical advantage" is, therefore, l_1/l_2.



LEVER.

Another mode of deducing the same formula is to consider the system displaced slightly when in equilibrium under the forces F_1 and F_2. The point of application of F_1 will move a distance x_1; that of F_2, a distance x_2. By the principle of energy $F_1x_1 = F_2x_2$; but by geometry, if the displacement is small, $\frac{x_1}{l_1} = \frac{x_2}{l_2}$, and hence $F_1l_1 = F_2l_2$, as before.

In some levers the fulcrum lies between the two balancing forces, e.g., pump handle, crowbar, scissors. In other cases it lies beyond the forces, e.g., sugar tongs, nutcracker, claw hammer, a wheelbarrow. The principle of the simplest form of lever was stated by Archimedes, and the more general principle was given by Leonardo da Vinci. See MECHANICS.

LEVER, lē′vẽr or lĕv′ẽr, CHARLES JAMES (1806–72). An Irish novelist, born in Dublin, Aug. 31, 1806. He graduated B.A. from Trinity College, Dublin, in 1827 and then studied medicine at Göttingen, Germany. A visit to Canada in 1829 he subsequently turned to good use in *Arthur O'Leary* (1844) and *Con Cregan* (1849). Returning to Dublin, he took his medical degree at Trinity (1831) and received several appointments from the board of health. In the *Dublin University Magazine* for February, 1837, appeared the first installment of *Harry Lorrequer* (pub. 1839). This was followed by *Charles O'Malley* (1841) and *Jack Hinton* (1843). These first three novels of Irish life, boisterous extravaganzas of fun and youthful spirits, represent their author at his best and are the stories that keep his fame alive. The pictures they afford of the life and characters of their day and country are, however, distorted by Lever's constant tendency towards caricature and exaggeration. This did not, and does not, interfere with their being immensely popular and highly entertaining. The military novel *Tom Burke of Ours* (1844) has also had a wide vogue. Of the long list of his novels the following, in addition to those already named, may be mentioned as perhaps best repaying perusal: *The Knight of Gwynne* (1847); *The Confessions of Con Cregan* (1849); *Sir Jasper Carew* (1855); *The Martins of Cro' Martin* (1856); *Sir Brooke Fosbrooke* (1866). After *Tom Burke* Lever's work showed a quieter humor and spread into a social survey of the Ireland of his time. It is in his Irish stories that he is always most at home, though he was moderately successful in depicting English and continental life and character, as in *The Dodd Family Abroad* (1853–54). After editing the *Dublin University Magazine* from 1842 to 1845, Lever lived mostly abroad and gathered material for his fiction there. In 1857 he was appointed Consul at Spezia and 10 years later at Trieste, where he died June 1, 1872. His *Works* were published by Routledge (33 vols., London, 1876–78; since reprinted), and in the Barrington edition (32 vols., Boston, 1902). Consult his *Life* by Fitzpatrick (London, 1879), and H. S. Krans, *Irish Life in Irish Fiction* (New York and London, 1903).

LEV′ERET (OF. *levret*, dim. of *levre*, Fr. *lièvre*, It. *lepre*, hare, from Lat. *lepus*, hare). The young of the hare during the first year of its age. See Hare.

LEV′ERETT, John (1616–79). An American Colonial official. He came to Boston with his father in 1633 from Boston Parish, England, but went back to serve in the Parliamentary army in 1644. He was a captain under Cromwell, who became his friend. On his return to Boston he was a member of the General Court (1651–52) and was sent to bring Maine under the jurisdiction of Massachusetts. He also took part in the capture of settlements along the St. Lawrence. In 1666 he went to England to represent the Colony and remained six years. On his return he was made Speaker of the General Court and major general of the militia. For six years he was in the Governor's Council and was then made Deputy Governor. When Bellingham died in 1672, he filled out his term. He was regularly elected Governor in 1673 and died in office. Consult the *Report of the New England Genealogical Society* for 1881.

LEVERRIER, le-vĕr′yȧ′, Urbain Jean Joseph (1811–77). A French astronomer, born at Saint-Lô. He was admitted to the Ecole Polytechnique in 1831 and was subsequently employed for some time as an engineer in connection with the government tobacco monopoly. His *Tables de Mercure* and several memoirs on "the secular inequalities" opened to him the door of the Academy in 1846. At the instance of Arago he applied himself to the examination of the disturbances in the motions of the planets, from which the existence of an undiscovered planet could be inferred, and, as the result of his laborious calculations, directed the attention of astronomers to the point in the heavens where, a few days afterward, the planet Neptune was actually discovered. The elements of the orbit of the planet had also been calculated by the English astronomer Adams in 1845, but no search was made for the planet. For this Leverrier was rewarded with the Grand Cross of the Legion of Honor, a professorship of astronomy in the Faculty of Sciences at Paris, and various minor honors. In 1854 Leverrier was appointed to the directorship of the Observatory of Paris, an office which, save during an interval of three years (1870–72), he held till his death. See Adams, John Couch; Neptune.

LEVERTIN, lĕv′ĕr-tēn′, Oscar Ivar (1862–1906). A Swedish critic, novelist, and poet, born near Norrköping, of Hebrew descent. He was educated at Upsala, where he obtained the doctorate (1888), became docent in literature there in 1889, and was appointed professor at Stockholm in 1899. His well-written critical works include: *Teater och drama under Gustaf III* (1889), *Gustaf III som dramatisk författare* (1894), *Från Gustaf III's dagar* (1896), *Svenska gestalter* (1903), and (an art monograph) *Niclas Lafrensen* (1899). At first a Realist, he wrote the novels *Småmynt* (1883) and *Konflikter* (1885); later, turning Romanticist, he published the collections of poems *Legender och visor* (1891), *Nya dikter* (1894), *Dikter* (1902), and *Kung Salomo och Morolf* (1905). Among novels of this period were *Lifvets fiender* (1891), *Rococonoveller* (1899), and *Sista Noveller* (1906). His *Samlade skrifter* were published (1907–14) in 30 volumes.

LE′VERWOOD. A synonym for ironwood. See Hornbeam.

LEVESON-GOWER, lo͞o′son-gōr′, Granville George. See Granville, second Earl.

LEVETZOW, lā′vet-sō, Ulrike, Baroness von (1804–99). A friend of Goethe. She met him at Marienbad and Karlsbad in 1822 and 1823, when she was 18 and he was 73. The poet was so carried away with her wit and beauty that he thought for a time of marrying her and addressed to her the poems which he afterward called *Trilogie der Leidenschaft*. Consult Suphan, *Goethe Jahrbuch*, vol. xxi (Frankfort, 1900), and Kirschoer, *Erinnerungen an Goethes Ulrike und an die Familie von Levetzow-Rauch* (Aussig, 1904).

LE′VI (Heb. *Lēwi*, probably a Gentilic form, possibly connected with *lāwah*, to join; Minæan *lawa*, fem. *lawat*, one attached to a sanctuary, priest, priestess). According to the Book of Genesis, the third son of Jacob and Leah (Gen. xxix. 34), eponymous ancestor of the Levites (q.v.). With his brother Simeon he is reported to have treacherously slaughtered the Shechemites for their outrage on his sister Dinah, an act for which Jacob administered a reproof (Gen. xxxiv) and even on his deathbed cursed Simeon and Levi, saying they should be scattered in Israel (Gen. xlix. 5–7). This curse is probably a reminiscence of tribal quarrels and refers to events which occurred after the entry of the Hebrews into Canaan. That both these tribes were practically wiped out appears to follow from the circumstance that Simeon occupies territory in Judah (Josh. xix. 1–9), while Levi has no territory at all. Neither of them plays any part in the political history of Israel or Judah. The remnant of Levi seems to have devoted itself to priestly functions, for which its special zeal for Yahwe at Kadesh Barnea appears to have fitted its members. (See Levite.) On the early Arabic term *lawa*, *lawat*, for priest, priestess, consult Mordtmann, *Beiträge zur minäischen Epigraphik* (Vienna, 1897); and Ed. Meyer, *Die Israeliten* (Halle, 1906).

LEVI, lā′vė, Hermann (1839–1900). A noted German conductor, one of the first and most influential exponents of Wagner, born at Giessen. From 1852 to 1855 he was a pupil of V. Lachner in Mannheim and then for three years of the Leipzig Conservatory. He began his career in 1859 as conductor in Saarbrücken.

From 1861 to 1864 he conducted the German operas at Rotterdam. Then he became court conductor at Karlsruhe and in 1872 was called to Munich. In 1882 he was chosen by Wagner to direct the first performance of *Parsifal*. An incurable affection of the brain necessitated his resignation in 1896. He died in Munich. As a composer, he became known through a concerto for piano and a number of songs. He also produced excellent translations of several opera librettos (Mozart, Berlioz, Chabrier).

LEVI, Leone (1821–88). An English economist, born in Ancona, Italy, of Jewish parentage. In 1884 he removed to Liverpool, where he was naturalized as a British citizen. A few notes to one of the Liverpool papers upon chambers of commerce and commercial tribunals led to the founding of such organizations in several of the leading cities. Levi became honorary secretary of the Liverpool Chamber of Commerce and was active in efforts for the improvement of the commercial law. His work on Commercial Law (1850–52) led to the creation of a royal commission and many important amendments. In 1852 Levi was appointed professor of commerce at King's College, London. He was an active participant in the work of the Statistical Society, the Law Amendment Society, and kindred organizations. His principal work was his *History of British Commerce and of the Economic Progress of the British Nation 1763–1870* (London, 1872). He died May 7, 1888.

LÉVI, lā'vē', Sylvain (1863–). A distinguished French Orientalist of Jewish descent. His interest in India was developed at an early age, and in 1886 he was appointed instructor in Sanskrit at the Ecole des Hautes Etudes. In 1890 Lévi received the degree of docteur ès lettres, for which his Latin thesis was *Quid de Græcis Veterum Indorum Monumenta Tradiderint*. The same year he published his French thesis on the Sanskrit drama (*Le théâtre indien*), which remains a standard. In 1894 he was appointed full professor in Sanskrit at the Collège de France. He also wrote *La doctrine du sacrifice dans les Brâhmanas* (1898); "Les Jâtakas; étapes du Bouddha sur la voie des transmigrations," in the *Annales du Musée Guimet*, vol. xix (Paris, 1906); "Mahâyâna-Sûtrâlamkâra," in the *Bibliothèque de l'Ecole des Hautes Etudes*, vol. clix (ib., 1907); "Le Népal: étude historique d'un royaume hindou," in the *Annales du Musée Guimet*, vols. xvii–xix (3 vols., ib., 1905–08); "Açvaghosa, le Sûtrâlamkâra et ses sources," in the *Journal asiatique*, vol. xii (ib., 1908); and *L'Apramâda-varga, étude sur les récensions des Dharmapadas* (ib., 1912). On Jan. 29, 1911, his pupils presented to him a volume of *Mélanges d'indianisme* on the anniversary of his twenty-fifth year as a professor in the Ecole des Hautes Etudes.

LE'VI, Son of Alphæus. See Matthew.

LEVI'ATHAN (Heb. *liwyāthān*). A monster mentioned several times in the Old Testament. The word is used both in a specific and a general sense. As a specific term (Ps. lxxiv. 14), it signifies the crocodile; but it is also used in a wider sense, as a kind of cloud snake which darkens the heavens (Isa. xxvii. 1), a large sea monster of uncertain kind (Ps. civ. 26), and as monster, or dragon, in an entirely general sense (Job iii. 8, Hebrew text; cf. Revised Version and Authorized Version, marginal reading); the description in Job xli. 1 also seems to indicate something more than a mere crocodile. (Cf. Schmidt, *Messages of the Poets*, New York, 1911.) As a mythical monster, the Leviathan appears also under various names such as *Rahab* and *Behemoth*, and it has been plausibly demonstrated by Gunkel (*Schöpfung und Chaos*, Göttingen, 1895) that the conception is allied to that of Tiamat, the dragon who in the Babylonian creation story is overcome by the god Marduk. Gunkel has proposed the theory that the Leviathan represented originally a mythological monster, fought with and overcome by Yahwe. The dragon which plays so prominent a part in the Apocalyptic literature of the New Testament and also appears in "Bel and the Dragon," a deuterocanonical addition to the Book of Daniel, reverts to the conceptions connected with Leviathan and Tiamat.

LEVIATHAN, The, or The Matter, Form, and Power of a Commonwealth, Ecclesiastical and Civil. A philosophical treatise by Thomas Hobbes (1651). It embodies Hobbes's views of politics, which he claimed emerged from primitive anarchy to their complete form in monarchy The idea of absolutism here advocated is Hobbes's most celebrated speculation.

LEVIATHAN OF LITERATURE, The. A title given to Dr. Samuel Johnson.

LEVIEN, lā'vēn', Ilse (1852–1908). A German novelist and lyric poet, whose pseudonym was Ilse Frapan. She was born at Hamburg and was for many years a teacher. In 1884 she went to Stuttgart to study æsthetics and was an intimate friend of Vischer for the last four years of his life. She wrote *Vischer-Erinnerungen* in 1889. Then she spent two years (1889–90) at Munich and was a member of Paul Heyse's literary circle. She married an Armenian by the name of Okuniam. Incurably ill, she was shot by her friend Emma Mandelbaum, who then shot herself. Her publications include: *Hamburger Novellen* (1886); *Zwischen Elbe und Alster* (1890); *Bittersüss* (1891); *Querköpfe* (1895); *Vom ewig Neuen* (1896); *In der Stille* (1897); the volume of poems, *Gedichte* (1891); *Die Betrogenen* (1898); *Phibje Ohrtens Glück* (1902), a comedy; *Arbeit* (1903), a novel; *Jugendzeit* (1904), a tale; *Die Retter der Moral* (1905), a drama; *Erich Hetebrink* (1907), a novel. Consult H. Spiero, in *Deutsche Geister* (Leipzig, 1910).

LEVIN, lā-vēn', Rahel. See Varnhagen von Ense, Rahel Levin.

LEV'IRATE MARRIAGE (from Lat. *levir*, Gk. *δαήρ*, *daēr*, Skt. *dēvara*, AS. *tācor*, OHG. *zeihhur*, husband's brother). The marriage of a man to the widow of his deceased brother. This was an ancient usage widely prevalent at certain stages of civilization and rests ultimately upon the circumstance that the wife as the property of a man passed at his death with his estate to his heir, upon whom the obligation rested to provide for the widow and her children, or, if there were no children, to secure issue. Gen. xxxviii is an example of this usage. The ancient custom is carried over into the Deuteronomic Code (Deut. xxv. 5–10), where provision is made that a man must marry his deceased brother's widow in case no son is born of the first marriage. However, certain modifications are introduced which indicate a departure from the earlier custom. The obligation rested on a surviving brother only in case he "dwelled together" (i.e., on the family estate) with the deceased; and while formerly all the male offspring of the second marriage were regarded as the issue of the deceased, according to Deuteronomy only the eldest son of the new marriage was to be so considered. It appears also that, even with these modifications, the custom was falling into disuse, for the Deuteronomic Code provides a ceremony whereby a surviving brother can evade the obligation, though in doing so he is subjected to an insult by the widow, who draws off her brother-in-law's sandal and spits in his face. The situation in the postexilic Book of Ruth implies this custom, though still further modified. The brother of Elimelech upon whom rested the obligation to marry Naomi forfeits the privilege and also the duty to redeem the field which Naomi was forced to sell, but there is no longer connected with the formal repudiation any such ceremony of public obloquy as is prescribed in Deuteronomy. In Lev. xviii. 16; xx. 21, marriage with a deceased brother's wife is forbidden without qualification and evidently because of economic abuses to which the ancient custom led with advancing social culture. The contradiction between Deuteronomy and Leviticus was embarrassing to the Jewish rabbis. In the days of Jesus the levirate law was still observed in certain circles, but the Talmud effects a compromise by recognizing the validity of the prohibition in Leviticus, but insisting upon the performance of the ceremony prescribed in Deuteronomy, which is still observed among orthodox Jews. Consult Nowack, *Hebräische Archäologie* (Freiburg, 1894), and Benzinger, *Hebräische Archäologie* (2d ed., Tübingen, 1907).

LEVIS, lē'vĭs; *Fr. pron.* lå'vē', or Point Levi. A town and the capital of Levis Co., Quebec, Canada, on the south bank of the St. Lawrence River, opposite the city of Quebec, and on the Quebec Central, the Grand Trunk, and the Intercolonial railroads (Map: Quebec, G 4). Steam ferries run to the city of Quebec. It has excellent docking facilities. Among the public buildings and institutions are a classical college, Roman Catholic convents, and hospitals. Manufacturing establishments include a shipyard, tanning, knitting, boot and shoe, wax-taper, and cigar factories, a saw mill, a foundry, and machine shops. Levis is protected by fortifications crowning the heights from which General Monckton bombarded Quebec in 1759. Pop., 1901, 7783; 1911, 7452.

LÉVIS, lå'vē', François Gaston, Duke of (1720–87). A French soldier, born at Château d'Ajac, Languedoc. After serving with distinction in the army in Bohemia, Germany, and Italy during the War of the Austrian Succession, he was sent to Canada (1756), where he was second to Montcalm in the campaigns against the British. He was promoted major general for his leading share in the successful defense of Carillon (1758) against a far superior force of English. He repulsed General Wolfe at Montmorency (1759) and after the death of Montcalm took command of the remnants of the French army. He kept up a hopeless but gallant fight against the conquering British for two years. In the battle of Sainte Foy (1760) he won a victory over them that would have resulted in Quebec changing hands once more had the French instead of the English ships arrived with the opening of navigation. After his return to France Lévis was made lieutenant general in 1761, served in the Rhine campaigns, was with Condé at the victory of Johannisburg, and became Governor of Artois in 1765, a marshal of France in 1783, and Duke in 1784.

LEVI'TA, Elias, or Elia Levi ben Asher, surnamed Ashkenazi, the German; Ha-bachur, the Master; and Ha-medakdek, the Grammarian (c.1468–1549). A Jewish grammarian and exegete. He was born at Neustadt-on-the-Aisch, near Nuremberg, about 1468. In 1496 he went to Italy, where he taught Hebrew mainly, if not solely, to Christians. He first taught in Venice, then in Padua, and next in Rome, where he had Cardinal Egidio as a pupil. From Rome he returned to Venice, and here he gave lessons to the French Ambassador, George de Silve; then he went to Isny, in Swabia, and finally returned to Venice. No Jews were allowed to live in France at this time, but Elias Levita received the unique honor of an invitation—which he declined—from King Francis I to come to France and teach the Hebrew language. He died in Venice in 1549. His principal works are a Hebrew grammar, entitled *Bahur* (1518); a treatise on the Masora, *Masoreth ha-Masoreth* (1538), important for the study of the Hebrew text of the Old Testament; and a dictionary of the Targum, *Meturgeman* (1541). His book, *Tishbi* (1541), a compilation of 712 articles treating chiefly of Rabbinic Hebrew, and his *Tub Taam*, a treatise on accents in biblical Hebrew, also deserve mention. Elias Levita's Hebrew knowledge was derived mainly from the works of the *Kimchis* (q.v.).

LE'VITE (Lat. *Levites*, Gk. Λευίτης, *Leuites*, from Heb. *Lēwi*, possibly connected with the S. Ar. *lawa'*, priest or temple attendant, fem. *lawa't*, priestess). The designation in the Pentateuch for servitors attached to the sanctuary of Yahwe. The usage of the term Levite in different parts of the Pentateuch differs in an important particular. In Deuteronomy the priests are referred to as "the Levite priests," a distinction between priest and Levite being apparently unknown at the time of the introduction of this code (c.620 B.C.). Ezekiel, however, makes a distinction between priests of the family of Zadok, who presided over the temple from the days of Solomon, and Levites (chaps. xliii–xlv). By Levites are meant the former priests of the sanctuaries (or high places) in Israel and Judah, which by the Deuteronomic Code had been abrogated in order to make possible the centralization of the cult in the temple at Jerusalem. These Levites, as a punishment for maintaining a cult that to the later writers appeared idolatrous, were to be degraded to the position of temple servants, subordinate to the Zadokites. This distinction seems to be fully carried out in Leviticus and Numbers. A compromise is effected between the priests of Jerusalem and those who served in the other sanctuaries by recognizing the descent of all from an eponymous ancestor, Levi; but, on the other hand, within this tribe special prerogatives are accorded to a particular family—that of Aaron, to whose hands the priesthood proper is intrusted. This did not involve the setting aside of the privileges of the Zadokites, whose descent was reckoned from Aaron through the latter's son Eleazar (1 Chron. xxiv. 3), while removing any opprobrium attached to the Levites by emphasizing a common origin with the priests. It is evident, from a consideration of this development in the use of the term Levite, that it originally designated a priest. (See Levi.) This seems to be the meaning also of the Minæan word *lawa'* (fem. *lawa't*) found in three inscriptions from El Oela. The connection of Levite as priest with the tribe of Levi goes back to very early times. A Levite is engaged as priest by Micah in his sanctuary on Mount Ephraim (Judg. xix–xxi). The ancient tribe of Levi, as we see from Gen. xlix. 5, was warlike, and the story of the treacherous attack of Simeon and Levi upon Shechem (Gen. xxxiv) is thought by some scholars to be an illustration of the secular character of this tribe and also an indication of its having been practically annihilated. But a violent zeal for Yahwe is not inconsistent with the essentially priestly character of the clan, and the destruction is likely to be only partial. Some historians think that the Levites were originally settled in and around Kadesh Barnea (q.v.). (See MOSES.) The Levites and their neighbors, the Simeonites, seem to have been driven out of their home in the Negeb by the Jerahmeelites. (See JERAHMEEL.) An attempt to settle farther north, similar to that of the Danites, appears to have failed. Simeon was in part absorbed in Judah (q.v.). Some remnants of Levi became attached to sanctuaries as guardians or priests. Gradually all priests were traced back to Levi, and the tribe as a whole was regarded as consecrated to the service of Yahwe as a substitute for the offering of the first-born in each Israelitish family, who rightfully belonged to the deity (Num. iii. 12). As servants of the sanctuary, supported by the temple income, the Levites were not obliged to cultivate the land and hence owned no territory. An exemption was made in respect to the cities of refuge, which were assigned to the priests, but which were merely old sanctuaries recognized as sacred asylums to which murderers fled from the avenger of blood (q.v.).

The duties of the Levites are specified in various parts of the Pentateuch (q.v.) and elaborated in the books of Chronicles. They were not properly servants of Yahwe, but servants to the Aaronite priests to whom they were "given." They were not permitted to approach the inner sanctuary. They had charge of the sacred vessels and prepared the animal for the sacrifice. Menial duties, such as the cleaning of the vessels and of the temple halls, were also imposed on them, as well as "watch" duties. According to Leviticus, one-tenth of the tithes only belonged to the Levites; but it would appear from the Book of Nehemiah that their income in fact was larger. Not all of the provisions, it must be borne in mind, were carried out; and, on the whole, the position of the Levites, who so far outnumbered the priests proper, was evidently better than the Pentateuch would lead us to suppose.

LEVIT'ICUS (Lat. Leviticus, Gk. *Λευιτικόν*, *Leuiticon*, pertaining to the Levites, from *Λευίτης*, *Leuites*). The name of the third book of the Pentateuch, derived from the title given to it in the Greek translation, "the Levitical book," as treating chiefly of the functions of the Levites, the term Levitical being used as synonymous with "sacerdotal." Like Exodus and Numbers, however, it contains also historical material and is viewed by many critics as part of a great historical compilation in which the legal codes have been inserted at the point at which, according to the historical theory underlying the Pentateuch (q.v.), they were promulgated. Leviticus may be divided into the following sections: (1) the Sacrificial Code, i–vii; (2) the story of the consecration of priests, viii–x; (3) the Purification Code, xi–xv; (4) the ritual for the Day of Atonement, xvi; (5) the Holiness Code, xvii–xxvi; (6) the Commutation Code, xxvii. Of these section (1) contains the laws concerning sacrifices systematically arranged with reference to (*a*) burnt offerings, (*b*) meal offerings, (*c*) peace offerings, (*d*) sin offerings, and (*e*) trespass offerings. To these are added a series of rules chiefly for the guidance of the priests, and some further specifications with regard to the various kinds of offerings. To the account of the consecration of priests in section (2) there have been added (chap. x) the stories of Nadab and Abihu, two sons of Aaron who incurred the wrath of Yahwe by carrying unhallowed fire in their censers, and of Eleazar and Ithamar, the sons of Aaron that were left, after their older brothers had been devoured by fire because of their ceremonial error, who likewise angered Yahwe by burning the goat of the sin offering instead of bringing the blood into the sanctuary and eating the flesh, but whose error was forgiven as a sin of ignorance. Section (3) deals with cleanness and uncleanness in general. The beginning is made with clean and unclean animals, which are enumerated in detail, with their distinguishing signs, and the consequences of defilement by contact with unclean animals and the carcasses of clean animals (chap. xi). In chap. xii uncleanness connected with childbirth is defined, and regulations for purification are given. Chap. xiii treats of skin diseases as causes of uncleanness, examination of signs pointing to leprosy, and discrimination between innocent eruptions and genuinely "unclean" symptoms. Chap. xiv makes application of the method to stuffs, cloth, leather, and to spots on the wall, and indicates methods of purification. Chap. xv deals with uncleanness resulting from sexual secretions and discharges in men and women. In section (4) the precautions are set forth which must be observed by the priests to prevent a misfortune like that related in chap. x. Incidentally to these prescriptions an old piacular ritual is introduced which involves the sending away of a scapegoat into the wilderness. This rite is carried over into the solemn celebration of the Atonement Day. Section (5), which has been called since Klostermann "the Holiness Code" because of the prominence attached in it to the "holy" character of the Jewish people, deals with the following topics: the slaughtering of domestic animals for offerings to Yahwe and prohibition against the eating of blood (xvii); laws against incest set forth in detail (xviii); miscellaneous commandments of a moral and social character (xix); prohibition of the Moloch cult and another law of incest (xx); regulations for priests, restrictions in regard to mourning and marriage, priests to be without physical blemish, ordinances with regard to the eating of sacrificial animals, which must also be without blemish (xxi–xxii); order and nature of festivals (xxiii); ordinances regarding oil for lamps in the tabernacle, shewbread, blasphemy, manslaughter, and torts (xxiv); Sabbatical year and Jubilee (xxv); the whole concluding with remarks of a hortatory character (xxvi). Section (6) deals with vows, estimations, and commutations on account of poverty.

It is evident that minor compendia of law have been united in this book. The Sacrificial Code (i–vii), the Purification Code (xi–xv), and the Holiness Code (xvii–xxvi) stand out prominently. But even these seem to represent a gradual growth. There are elements that are manifestly old, and others that have the appearance of being later accretions. Thus, in i–vii we find a group of instructions to priests which appear to embody relatively ancient practices with additions (vi. 8–vii. 2), while i. 1–vi. 7 seem to be supplements to the subject dealt with in this group of regulations. In general the distinctions between the different kinds of sacrifices and the manner of offering them are likely to go back to preëxilic times, though later additions may have been made. Again the regulations for taboos of food, persons, and objects clearly rest upon ancient customs which the Jews shared with surrounding nations, and even the formulation of the ordinances may be relatively old, though in their present form they seem to betray evidences of having passed through several editing stages. Many of the ordinances in the Holiness Code, particularly those in reference to the slaughter of animals, the lamps, and the shewbread, are unquestionably based on older customs and decisions, which, however, may have been elaborated and revised. This juxtaposition of old and new is especially noticeable in chap. xvi, where the ritual of the scapegoat, a survival of demon worship bearing on its face the mark of primitive conceptions of sin, is connected with the Atonement Day, of which no mention is made in codes that seem to be earlier than the exile, and which has the appearance of being distinctly a feature of postexilic Judaism. Editorial activity seems to be indicated by the separation of this chapter from chap. x, to which it alludes, by the Purification Code; by the introduction, after the Sacrificial Code, of a narrative recording how the priests were solemnly consecrated to offer them; and by the last chapter, which looks like a later addition. Chap. viii appears to belong to Exodus xl, while chap. ix is directly connected with Exodus xxv–xxix. A certain rearrangement seems to have taken place, involving the tearing apart of component pieces, and the desire to give an historical setting to the codes is manifest.

Modern critics were at first inclined to regard all the legislative material of this book as a part of a great corpus, embodying both legislation and narrative, which they called the Priests' Code. A distinction between the Holiness Code and the other ritual compendia was clearly seen by Klostermann and is now generally recognized. From a comparison of the Holiness Code with Ezekiel xl–xlviii (see EZEKIEL) and other sections of the Pentateuch, many scholars inferred that the former was written in the Exile, after the time of Ezekiel, but earlier than other parts of the Levitical legislation. Other students, however, maintained that it was wholly or substantially earlier than the exile. There is as yet no consensus of opinion in regard to this subject, but there is a tendency to admit that many parts of this code belong to the period of the Kingdom of Judah. Gradually the higher age of much of the material embodied in the other codes found in the Book of Leviticus is becoming recognized. The so-called Priests' Code is dissolving itself into fragments of different nature which cannot all be assigned to the same time, and there is a growing number of independent scholars who are no longer able to maintain the separate existence of such a code. Like the other books of the Pentateuch, Leviticus seems to have preserved to us many regulations that are much earlier than the estimate until recently prevalent among scholars would allow, while it also contains many late editions. See PENTATEUCH.

Bibliography. Commentaries of Kalisch (2d ed., 1872), Keil (2d ed., 1872), Dillmann (1880; 2d ed., by Ryssel, 1897), Strack (1894), Baentsch (1900), Bertholet (1901); Klostermann, *Der Pentateuch* (Leipzig, 1893); Baentsch, *Das Heiligkeitsgesetz, Lev. xvii–xxvi* (Erfurt, 1893); Driver and White, "Leviticus," in Haupt, *Sacred Books of the Old Testament* (ib., 1894; Eng. trans., New York, 1898); Addis, *Documents of the Hexateuch*, vol. ii (London, 1898); Carpenter and Battersby, *The Hexateuch* (ib., 1900); Erdmans, *Alttestamentliche Studien*, vol. iv (Giessen, 1912).

LEVITOV, lĕ-vē′tôf, ALEXANDER IVANOVITCH (1835–77). A Russian writer of folk tales. He was born in the Government of Tombov and at eight helped his father, a country priest, conduct a parish school. Frequent jaunts in the adjacent steppes early gave him that love and knowledge of nature which characterize his tales. After an elementary education in a clerical school he went afoot to Moscow to enter the university, but harsh treatment at the hands of its officials caused him to leave. Going to St. Petersburg (also on foot), he entered a medical school in 1855. From there he was expelled for some indiscretion and exiled in the Far North, where, friendless and penniless, he took to drink—a habit which was never to be broken and which, after years of untold misery, brought on his untimely end.

Levitov's work largely reflects his own sad life. His themes are almost invariably the misery of poor folk in village, city, and town, prosaic, everyday adventures, with hardly any plots or intrigues. But there is such a note of sympathy and such an abundance of poetic color in his descriptions that his plotless tales make fascinating reading. Nor is there any trend or tendency about his characters—he has no heroes—to remind one of other writers of the underworld (Gorky, e.g.); his are purely impressionist sketches, in which what is told matters less than how it is told. Into the spiritual struggles of men and women this writer does not enter. Levitov's best-known collections of stories are *Sketches of the Steppe* (1865), written in exile and charmingly reminiscent of his childhood; *Moscow Dens and Slums* (1868), *The Sorrows of Country, Highway, and Town* (1874), a mixed collection of tales faithfully and lovingly depicting low life as the author knew it. The latest complete edition of his works (8 vols., St. Petersburg, 1911) contains a good biographical study and a complete bibliography.

LEVKAS, lĕf-kȧs′. See Amaxichi.

LEVKOSIA, lĕf-kō′sē-ȧ. Another name for Nicosia (q.v.).

LEV′ULOSE. See Sugars.

LEVY (Fr. *lever*, to raise). A body of men raised or collected for military purposes, usually by authority of the state. A *levy in mass* (Fr. *levée en masse*) is the assemblage of all citizens fit for military service. See Armies; Conscription; Recruitment.

LEVY (OF. *levee*, Fr. *levée*, a raising, embankment). In its legal sense, the seizure and taking possession of the property of a person, by a proper officer, under a writ or other process of law directing such action. It was formerly specifically used to designate the proceedings in connection with a fine (q.v.) of lands, but this has fallen into disuse. The most common employment of the term is to describe the act of a sheriff, marshal, or other officer, whereby he seizes the property of a judgment debtor under an execution (q.v.), or writ of fieri facias (q.v.), for the satisfaction of the judgment.

To constitute a valid levy the officer must take actual possession of the property. In case of personal property he should retain actual custody of it, either by locking it up or putting a deputy in charge of it; in case of real property he should enter and show by open and unequivocal acts that he has taken legal possession under his process, but in most states the judgment debtor is not ejected from the property, as his possession is subject to the levy and subsequent sale. In making a levy the officer does not act as the agent of the person in whose behalf it is made, but acquires an independent possession, as bailee, of the goods so levied on by him, and as such he is liable for any misuse thereof or for negligence resulting in its loss or injury.

The term "levy" is also applied to the seizure of property under a writ of attachment. The rules as to taking possession of the property of the person against whom such a writ is issued are similar to those under an execution against property. See Attachment; Execution; Sale; Sheriff; and consult the authorities there referred to.

LÉVY, Auguste Michel (1844–1911). A French geologist. He was born in Paris and was educated at the Ecole Polytechnique and at the Ecole des Mines. Attached after 1876 to the Geological Survey of France, he had a very important part in the development of this service. In 1896 he was elected a member of the Academy of Sciences. His publications include: *Structure des roches éruptives étudiées au microscope* (1876) and *L'Explication de la carte géologique de la France* (1879), with F. Fouqué; *Synthèse des minéraux et des roches* (1888) and *Tableaux des minéraux des roches* (1889), with A. Lacroix; *Structures et classification des roches éruptives* (1889).

LEVY, lā′vē, Jakob (1819–92). A Jewish Orientalist, born at Dobrzyze in Posen. He was educated at Breslau, in 1845 became rabbi at Rosenberg and in 1850 went to Breslau, where he taught (1871–75) in a Jewish school. In 1875 he was appointed professor in Breslau University. His principal works are *Chaldäisches Wörterbuch über die Targumim* (1867–68) and a *Neuhebräisches und chaldäisches Wörterbuch über die Talmudim und Midraschim* (1876–89).

LEVY, Louis Edward (1846–1919). An American photochemist, born at Stenowitz, Bohemia. Having come to the United States in childhood, in 1866 he made special studies at the University of Michigan. He investigated microscopic photography in 1869–70, invented photochemical engraving ("Levytype") in 1875, and founded the Levytype Company. In 1896, with his brother, Max Levy, he received the John Scott Legacy medal (Franklin Institute) for inventing the Levy line screen; and he was awarded the Elliott Cresson gold medal in 1900 for the invention of the acid blast and again in 1907 for his etch-powdering machine, and gold medals at the Paris Exposition (1900) and the St. Louis Exposition (1904). He is author of *The Jewish Year* (1895); *The Russian Jewish Refugees in America* (1895); *Business, Money, and Credit* (1896); *Cause of Business Depressions* (1914), with Hugo Bilgram.

LÉVY, Raphaël Georges (1853–). A French economist, born in Paris, where he was educated at the Lycée Louis-le-Grand and at the Ecole de Droit. After 1886 he turned his attention to the study of political economy and wrote widely for periodicals on laws of exchange, variations of national credits, economic crises, and like topics. He became professor of political economy at the Ecole Libre des Sciences Politiques and was elected in 1913 a member of the Académie des Sciences Morales et Politiques. His writings include: *Le péril financier* (1888); *La spéculation et la banque* (1893); *La vraie Amérique* (1894); *Les chemins de fer français* (1894); *Le monopole de l'alcool* (1897); *Les finances des Etats-Unis* (1898); *La dette anglais* (1898); *Le mouvement industriel* (1899); *Les finances égyptiennes* (1899); *Allemagne industrielle* (1901); *Finances de guerre: Russie et Japon* (1904); *Principes de monnaie de banque* (1905); *Banques d'émission et trésors publics* (1911).

LEWAL, le-vȧl′, Jules Louis (1823–1908). A French general. He was born in Paris, entered the army in 1846, participated in the Crimean War, served in the Italian campaign of 1859, with the French troops in Mexico (1862), and, after coöperation with Niel in the army reforms, in the Franco-Prussian War. He was promoted to brigadier in 1874, was head of the Military Academy (1877–80), in 1885 was Minister of War in Ferry's cabinet, and in 1888 was appointed inspector general. He wrote: *La réforme de l'armée* (1871); *Etudes de guerre* (1872, 1890); *Tactique* (1875–90); *Stratégie de marche* (1893); *Stratégie de combat* (1895 et seq.).

LEWALD, lā′vȧlt, August (1792–1871). A German author and theatre manager, born at Königsberg. He entered the Russian service at Warsaw, as Secretary, during the War of Liberation. He became an actor, and after 1818 he was manager and director of theatres at Hamburg, Stuttgart, and elsewhere. In 1835 he founded at Stuttgart the periodical *Europa*, which he conducted till 1846, and afterward became editor of the conservative *Deutsche Chronik*. A collection of his works, made by himself, was published in 12 volumes (1843–45), including the autobiographical *Aquarelle aus dem Leben* (1836–37 and 1840). Consult K. Gutzkow, in *Oeffentliche Charaktere* (Hamburg, 1835).

LEWALD, Fanny (1811–89). A German novelist and essayist, a cousin of August Lewald. She was born in Königsberg, of Jewish parents, but joined the Protestant church when she was sixteen. Travel developed her powers of composition, and in 1841 she published her first novel in *Europa*, under the title *Der Stellvertreter.* Four years later, after travels in Italy, she settled in Berlin, where she married Adolph Stahr (q.v.) in 1855. She wrote many novels and stories, among which may be mentioned: *Klementine* (1842); *Jenny* (1843); *Nella* (1870); *Die Erlöserin* (1873); *Neue Novellen* (1877); *Stella*, which has been translated into English (1884); *Die Familie Darner* (Berlin, 1888); *12 Bilder aus dem Leben* (Berlin, 1888). Her novels are characterized by close observation and hard realism. She also wrote sketches of travel and the autobiographical *Meine Lebensgeschichte* (1861–63); and, treating the question of woman's rights, of which she was an ardent supporter, *Osterbriefe für die Frauen* (1863) and *Für und wider die Frauen* (2d ed., 1875). Consult Frenzel, *Erinnerungen und Strömungen* (Leipzig, 1890), and G. Jansen, *Karl Alex. von Sachsen-Weimar in seinen Briefen an Fanny Lewald* (Berlin, 1904).

LEWCHEW, LEWKEW. See LUCHU.

LEWENHAUPT, lā′ven-houpt, ADAM LUDVIG (1659–1719). A Swedish general. He was born in a Swedish military camp near Copenhagen; studied at Upsala, Lund, Rostock, and Wittenberg; served in the Austrian army against the Turks, and under William III in Holland against the French; and in 1697 returned to Sweden. In the war waged by Charles XII against Peter the Great and his allies he was intrusted with the defense of Courland, and defeated the enemy in several engagements (1703–05). Lewenhaupt fought bravely at Poltava in 1709, and after that disastrous battle was forced to surrender the remnant of the Swedish forces to the Russians. He was for some time kept a prisoner in Russia, and during this period, after the death of Charles XII, he was made Swedish Councilor of State, but died before he could reach home to accept the office. His memoirs, edited by his son-in-law, were published at Stockholm in 1757.

LEWES, lū′ĭs. The capital of Sussex, England, on the Ouse, 50 miles south of London, and 7 miles from Newhaven, its port (Map: England, F 6). It contains the ruins of a Cluniac priory founded in 1078 by Gundrada, stepdaughter of William the Conqueror, whose body is still preserved in a chapel of the old Norman church of St. John's Southover. A free grammar school was founded and endowed in 1512. It has also a school of science and art, a free library, a county hall, and a town hall. There are large annual sheep fairs. The Norman castle still stands and the well-preserved keep houses a small museum. The finest modern building is the Fitzroy Memorial Library, designed by Sir Gilbert Scott. Near Mount Harry-on-the-Downs occurred the battle of Lewes, in which Henry III was defeated (May 14, 1264) by the insurgent barons under Simon de Montfort. Lewes is of remote origin. Roman coins have been discovered in the neighborhood, and there are traces of ancient mounds. It was a royal demesne of the South Saxon rulers, and mints were established there by Athelstan. Pop., 1901, 11,249; 1911, 10,972. Consult: Horsfield, *History of Lewes* (2 vols., Lewes, 1824–27); Mantell, *The Ancient Town of Lewes* (London, 1846); *Victoria History of the County of Sussex*, vol. ii (ib., 1907).

LEWES. A city in Sussex Co., Del., on Delaware Bay, 42 miles southeast of Dover, on the Maryland, Delaware, and Virginia and the Pennsylvania railroads, and on the Lewes on Assowoman Canal (Map: Delaware, J 3). It has a good harbor, artificially secured by a stone breakwater; is the headquarters of the Delaware Bay pilots; and exports large quantities of vegetables, fish oils, and fruit to Northern markets. There are tin-box factories, a shirt factory, and several tomato canneries. Among the interesting features of the place are the Cape Henlopen Lighthouse, built in 1800, the Federal building, and the sand dunes, 3 miles long. The water works are owned by the city. Pop., 1910, 2158.

LEWES, GEORGE HENRY (1817–78). An English author. He was born in London, April 18, 1817, was educated at various schools, entered upon a commercial career, studied medicine, and finally resolved to devote himself to authorship. In his twenty-first year he proceeded to Germany, where he remained for two years, studying the life, language, literature, and philosophy of that country. On his return to England he took up his residence in London and began to write for the newspapers and magazines, till finally he became one of the most successful of littérateurs. Lewes edited with admirable talent the *Leader*, from 1850 to 1854; composed novels, comedies, and tragedies, and ultimately turned his active mind to the study of physiology and cognate branches of science, in which he won considerable repute. He married Agnes Jervis in 1840, but the union was unhappy and he separated from her in 1854 to live with Marian Evans (George Eliot) as man and wife. His principal works are: his *Biographical History of Philosophy from Thales to Comte* (1845), a new edition of which, much enlarged, was afterward published; *The Spanish Drama, Lope de Vega and Calderon* (1846); *Comte's Philosophy of the Sciences* (1853), a work which is not a mere translation of the French savant, but in several parts a complete remodeling; *Life and Works of Goethe* (1855); *Seaside Studies at Ilfracombe* (1858); *Physiology of Common Life* (1859); *Problems of Life and Mind* (1874–79); *On Actors and the Art of Acting* (1875). In 1865 Lewes founded the *Fortnightly Review*, and for a time was its editor. He died Nov. 30, 1878. In philosophy he leaned towards positivism (q.v.), but he developed his views with considerable originality. His *History* was written to prove the unattainability of metaphysical truth, although in his later writings he admitted the possibility of an empirical metaphysics. Consult the *New Quarterly* (London, October, 1879), and J. W. Cross, *George Eliot's Life as Related in her Letters and Journals* (3 vols., New York, 1885).

LEWES, MISE OF. See MISE OF LEWES.

LEWIN, lȧ-vēn′, GEORG RICHARD (1820–96). A German physician, born at Sondershausen. He studied medicine in Berlin, Halle, Leipzig, Heidelberg, Vienna, and Paris. After several years of charitable work he was made professor of dermatology at Berlin in 1868. He was best known for his novel treatment of laryngitis and of syphilis, as set forth in *Die Inhalationstherapie in Krankheiten der Respirationsorgane* (2d ed., 1865) and *Die Behandlung der Syphilis durch subkutane Sublimatinjektion* (1869).

LEWIN, lū′ĭn, THOMAS (1805–77). An English lawyer and biblical scholar. He was educated at Trinity College, Oxford; admitted to the bar in 1833, and in 1852 became conveyancing counsel to the Court of Chancery, and held the office the rest of his life. He wrote a standard treatise on *The Law of Trusts* (1837; 8th ed., 1885), but most of his works are of a religious character. Among them are: *The Life and Epistles of Saint Paul* (1851; 5th ed., 1890); an *Essay on the Chronology of the New Testament* (1854); *Jerusalem, A Sketch of the City and Temple from the Earliest Times to the Siege by Titus* (1861); *Siege of Jerusalem by Titus* (1863); and *Fasti Sacri, or a Key to the Chronology of the New Testament* (1868). He also published a work on Cæsar's invasion of Britain (1859; 2d ed., 1862).

LEWIS, or Lewis Fork. The old name of Snake River (q.v.).

LEWIS, lū′ĭs, Abram Herbart (1836–1908). An American clergyman of the Seventh-Day Baptist denomination. Born at Scott, N. Y., he studied at Milton College (Wisconsin), Alfred University (New York), and Union Theological Seminary. He held charges in Westerly, R. I. (1864–67); in New York (1868); and in Plainfield, N. J. (1880); became professor of Church history at Alfred University in 1868; and wrote: *Critical History of the Sabbath and the Sunday in the Christian Church* (1886; 2d ed., 1903); *Sunday Legislation* (1888; new ed., 1902); *Paganism Surviving in Christianity* (1890); *Swift Decadence of Sunday* (1899); *Spiritual Sabbathism* (1910).

LEWIS, Agnes Smith (?–). An English Orientalist, daughter of John Smith, a Scottish jurist of Irvine, Ayrshire, where she was born about the middle of the nineteenth century. She was educated at the Irvine school until 12 years of age, then at Birkenhead and London in private schools and by tutors. She became especially proficient in modern Greek, Arabic, and Syriac. Before her marriage in 1887 to the Rev. Samuel Savage Lewis (1836–91), fellow of Corpus Christi College, Cambridge, she wrote a number of novels and accounts of travel, among the latter *Glimpses of Greek Life and Scenery* and *Through Cyprus*. With her twin sister, Mrs. Margaret Dunlop Gibson (q.v.), she discovered, in 1892, in the library of the convent of St. Catherine on Mount Sinai, the palimpsest containing the Four Gospels in Syriac, representing the oldest text yet known of any part of the New Testament, probably as it existed in the second half of the second century A.D. In 1896 the sisters brought back the first leaf of the Hebrew Ecclesiasticus (q.v.). Mrs. Lewis received honorary degrees from Halle, Wittenberg, St. Andrews, Heidelberg, and Dublin. She and Mrs. Gibson gave the site for Westminster Theological College, Cambridge, in 1897. Mrs. Lewis's works include: a biography of her husband (1892); an introduction to the edition by Bensly, Rendel Harris, and Burkitt of *The Four Gospels from the Sinaitic Palimpsest* (1894; revised by her as *The Old Syriac Gospels*, 1910); *In the Shadow of Sinai* (1898); *The Story of Aḥikar*, with Conybeare and Harris (1898, 2d ed., 1913); *A Palestinian Syriac Lectionary of the Gospels*, with Mrs. Gibson (1900); and several volumes in *Studia Sinaitica* and *Horæ Semiticæ*, published by herself and Mrs. Gibson.

LEWIS, Alfred Henry ("Dan Quin") (1858–1914). An American author and journalist, born in Cleveland. At 21 he was city attorney of Cleveland; later a cowboy in the Southwest, a lawyer in Kansas City, and a correspondent at Washington of the Chicago *Times* and then of the Hearst papers. For a time after 1898 he edited *The Verdict*, a political weekly published by Perry Belmont in New York. Lewis became best known by his "Wolfville" stories, the product of his acquaintance with the small frontier town. In the capacity of attorney he advised Harry K. Thaw (q.v.) in 1913 that no crime would be committed if Thaw effected his escape from Matteawan Insane Asylum. His writings include: *Sandburrs* (1900); *Wolfville Days* (1902); *Wolfville Nights* (1902); *The Black Lion Inn* (1903); *Peggy O'Neal* (1903); *The Sunset Trail* (1905); *Confessions of a Detective* (1906); *The Story of Paul Jones* (1906); *The Throwback* (1906); *When Men Grew Tall* (1907); *An American Patrician—Aaron Burr* (1908); *Wolfville Folks* (1908); *The Apaches of New York* (1912); *Faro Nell and her Friends* (1913); *Nation-Famous New York Murders* (1914).

LEWIS, Andrew (c.1720–80). An American soldier. He was born in Donegal, Ireland, but in 1732 his family emigrated to America and became the first white settlers within the limits of the present Augusta Co., Va. Lewis served as a major under Washington in the Ohio expedition of 1754, and under Braddock, with the same rank, in 1755. In 1756 he commanded the Sandy Creek expedition against the Indians, and two years later was captured by the French near Fort Duquesne and taken as a prisoner to Montreal. He was Virginia's commissioner in the treaty negotiations with the Indians at Fort Stanwix (Rome, N. Y.) in 1768, and in 1774 served as brigadier general in Lord Dunmore's War (q.v.), and as such commanded the Virginia troops at the battle of Point Pleasant (q.v.). He was a member for several years of the Virginia House of Burgesses, and in 1776 was appointed by Congress a brigadier general in the Continental army, and took part in the military operations against Lord Dunmore. Ill health compelled him to resign his commission in April, 1777, and he died three years later in Bedford Co., Va. His four brothers, Samuel, Thomas, William, and Charles, were also prominent in the history of Virginia.

LEWIS, Charlton Thomas (1834–1904). An American lawyer and lexicographer, born in West Chester, Pa. He graduated from Yale College in 1853. In 1854–56 he studied for the Methodist ministry; in 1857 he became professor of languages in the State Normal University, Bloomington, Ill.; and later (1860) was appointed professor of mathematics in Troy University (New York) and (1862) professor of Greek in the same institution. Three years afterward he gave up teaching and settled in New York City for the practice of law. He spent the year 1867–68 in Europe on account of ill health; on his return he became editor, with William Cullen Bryant, of the New York *Evening Post*. In 1871 he again resumed his law practice and became counsel for many corporations. In 1898–99 he lectured on insurance before Columbia, Cornell, and Harvard universities. Among the many subjects which engaged his attention was that of prison reform. His principal published works are: *Gnomon of the New Testament*, translated from the German of Bengel (1861); *History of Germany* (1870); *Harper's Latin Dictionary* (1879), in collaboration with Prof. Charles Short; *Latin Dictionary for Schools* (1886); *Elementary Latin Dictionary* (1890).

LEWIS, Dio (1823–86). An American physician, born at Auburn, N. Y. He studied at the Harvard Medical School and practiced for a time successively at Port Byron and Buffalo, N. Y. At Buffalo he published a monthly periodical, in which he advocated the hygienic value of diet and exercise. He introduced a system of light gymnastics for schools and private classes, and in 1863 founded in Boston a school for training teachers of physical culture. He removed to New York City about 1883. His principal publications are: *The New Gymnastics* (1862); *Weak Lungs and How to Make Them Strong* (1863); *Talks about People's Stomachs* (1870); *Our Girls* (1871); *Chats with Young Women* (1871); *Chastity* (1872); *Gypsies* (1881); *In a Nutshell* (1883).

LEWIS, Edmonia (1845–). An American sculptor. She was born in New York, of negro and Indian parentage. She received little instruction in sculpture, but attracted attention by exhibiting a bust of Colonel Shaw at Boston in 1865. In the same year she went to Rome to study, and after 1867 made her residence there. Among her works are the "Freedwoman"; a curious and somewhat repulsively realistic statue, the "Dying Cleopatra," exhibited at the Philadelphia Exposition of 1876; "Asleep"; "Marriage of Hiawatha"; "Madonna with the Infant Christ." Among her portrait busts in terra cotta are those of Longfellow, Charles Sumner, John Brown, and Abraham Lincoln, in the library of San José, Cal. Her work, which shows talent and imagination, is mostly in Europe.

LEWIS, Estelle Anna Blanche (Robinson) (1824–80). An American poet. She was born near Baltimore, Md., and was married to Sidney Lewis of Brooklyn, N. Y., in 1841. From that time she lived chiefly in Europe. Her first verses appeared in New York as *Records of the Heart* (1844). Her later poems include: *The Child of the Sea* (1848); *The Myths of the Minstrel* (1852); *Poems* (1866). She also wrote three tragedies, *Helémah, or the Fall of Montezuma* (1864); *Sappho of Lesbos* (1868); *The King's Stratagem* (1869). Of these *Sappho*, her best work, passed through seven editions, and after being translated into Greek was produced at Athens.

LEWIS, Exum Percival (1863–). An American physicist, born in Washington Co., N. C. He was educated at Columbian (now George Washington) University (B.S., 1888), where he was instructor in physics (1891–95), and at Johns Hopkins University (Ph.D., 1895). At the University of California he served as an instructor in physics (1895–96), assistant professor (1896–1902), associate professor (1902–08), and as professor after 1908. He was a member of the Crocker eclipse expedition to the South Seas in 1908. He edited *The Effect of a Magnetic Field on Radiation* (1900) and contributed the sections on light and wave motion in Duff's *Text-Book of Physics* (1908).

LEWIS, Francis (1713–1803). An American patriot. He was born in Llandaff, Wales, and was educated at Westminster. After a mercantile apprenticeship he brought over a cargo of goods to America in 1735; settled in New York in 1737, and became a prosperous merchant. During the French and Indian War he was agent for clothing the British troops, was at Oswego when that post was surrendered to Montcalm by Colonel Mercer in 1756, and was taken prisoner and carried to France. On his return to New York he gradually retired from active business. He was prominent among the Sons of Liberty; was a member of the Continental Congress in 1774–79, and signed the Declaration of Independence. In 1776 his house on Long Island was plundered by the British, his papers destroyed, and his wife taken prisoner. After much trouble she was finally exchanged. Consult Jenkins, "Morgan Lewis" (son of Francis Lewis), in *Lives of the Governors of the State of New York* (Auburn, 1851).

LEWIS, Sir George Cornewall (1806–63). An English statesman and author, eldest son of Sir T. F. Lewis, of Harpton Court, Radnorshire. He was born in London, April 21, 1806. He was educated at Eton and at Christ Church, Oxford, where he was distinguished for classics and mathematics. He became a barrister in 1831, and after acting on various commissions of inquiry, succeeded his father as poor-law commissioner (1839–47). He sat in Parliament for Herefordshire from 1847 to 1852, and became successively Secretary to the Indian Board of Control, Undersecretary of the Home Department, and Financial Secretary to the Treasury. Losing his seat in 1852, he accepted the editorship of the Edinburgh *Review* (1852–55). Elected to Parliament for the Radnor Boroughs in 1855, he became, under Palmerston, Chancellor of the Exchequer (1855–58), Home Secretary (1859–61), and Secretary of State for War (1861–63). He died April 13, 1863. He wrote numerous articles for the magazines, especially for the Edinburgh *Review*, and published about 20 books on a great variety of topics. Among them are: *The Use and Abuse of Political Terms* (1832); *Origin and Formation of the Romance Languages* (1835); *Local Disturbances in Ireland* (1836); *A Glossary of Provincial Words Used in Herefordshire* (1839); *The Government of Dependencies* (1841); an edition of the spurious *Fables of Babrius* (1846); *The Influence of Authority in Matters of Opinion* (1849); *The Method of Observations and Reasoning in Politics* (1852); an *Inquiry into the Credibility of Early Roman History* (1855), an attack on Niebuhr; *Astronomy of the Ancients* (1862); and a *Dialogue on the Best Form of Government* (1863). Several of these works displaying solid learning have been reprinted. Consult *Letters of G. C. Lewis*, edited by G. F. Lewis (London, 1870), and Walter Bagehot, *Biographical Studies*, edited by Hutton (ib., 1881).

LEWIS, Sir George Henry, Bart. (1833–1911). An English lawyer. He was educated at University College, London, was admitted to the English bar in 1856, and soon made his reputation by the prosecution of the directors of Overend and Gurney's Bank when that institution failed. He appeared in many other famous cases, including the Colin Campbell divorce case and the Tranby Croft baccarat scandal. He prepared Parnell's case for the *Times* Parliamentary Commission hearing, and discovered that Richard Piggott had forged the alleged Parnell letters. He was created Knight in 1893 and Baronet in 1902, and seven years later he retired.

LEWIS, Henry Carvill (1853–88). An American geologist, born in Philadelphia. He graduated at the University of Pennsylvania in 1873 and spent several years in graduate study. In 1879 he became connected with the Geological Survey of Pennsylvania and in 1884 he published a *Report on the Terminal Moraine in Pennsylvania and New York*. A year afterward he went to Europe to study glacial phenomena in England, Ireland, and Switzerland, and to take courses in petrology under Rosenbusch at Heidelberg. His early death broke off these researches, but their partial results were contributed to the British Association (1886–87). In 1880 he was made professor of mineralogy in the Philadelphia Academy of Natural Sciences, and three years afterward was made professor of geology at Haverford College; both these chairs he held until his death.

LEWIS, Ida (1841–1911). An American life-saver, born at Newport, R. I. By a special Act of Congress, in 1878 she became keeper of Lime Rock Lighthouse, Newport harbor, of which her father had been keeper for many years. Expert at the oar and in swimming, she saved 22 lives between 1867 and 1904, receiving medals from the United States government, the Humane Society of Massachusetts, and the Life Saving Benevolent Society of New York. Her boat, the *Rescue*, presented to her by the citizens of Newport, was exhibited at the Columbian Exposition, Chicago, in 1893. She was married to William H. Wilson in 1870, but lived with him only a short time, and is commonly known by her maiden name.

LEWIS, James (1840–96). An American comedian. He was born in Troy, N. Y., and made his first stage appearance there in 1858, playing Farmer Gammon in *The Writing on the Wall*. At the outbreak of the Civil War he was in the South, and narrowly escaped being detained there by the blockade. Subsequently he traveled much in the Middle West. His first appearance in New York City was in 1866, in the farce *Your Life's in Danger*, presented at the Olympic Theatre by Mrs. John Wood's company. Afterward he was very successful in Boston in the rôle of Dick Swiveller. In 1869 he became the leading comedian in Augustin Daly's company in New York City, and he retained this position during the remainder of his life. He was highly successful in almost every comedy part that he played.

LEWIS, James Hamilton (1866–). An American lawyer and legislator, born at Danville, Va. After attending Houghton College, he ran away from home and located at Savannah, Ga. Friends assisted him to enter the University of Virginia and complete his education. Returning to Savannah, he studied law and was admitted to the bar in 1884. Two years later he removed to Seattle, Wash., where he practiced law successfully. Being elected in 1886 to the Territorial Legislature, he assumed leadership of the Democratic party, but in 1890 he declined nomination for Congress. In 1892 he was defeated for Governor of the new State, and was also unsuccessful as candidate for United States Senator in 1894 and 1899. In 1896, however, he was elected Congressman at large from Washington, and, although he served only one term, he became prominent as author of the resolution for the recognition of Cuban independence. His State presented him as a "favorite son" for the nomination for Vice President in 1896, and he was again mentioned for this place at Kansas City in 1900. In 1903 he was a member of the Joint High Commission on Canadian and Alaskan Boundaries which deliberated at London. Also in 1903 he moved his residence to Chicago, where he was corporation counsel for the city in 1905–07. He was given the Democratic nomination for Governor in 1908, and, although defeated by Deneen, his vigorous campaign made him widely known. In 1913, by virtue of a compromise with the Republicans whereby that party was to have the short-term senatorship, he was elected to the United States Senate for a full term. As whip of the Democratic party, he supported the Wilson administration consistently.

LEWIS, John (1858–). A Canadian journalist. He was born and educated in Toronto, studied law, and in 1881 joined the staff of the Toronto *World*, and afterward at various times until 1892 was connected with the Winnipeg *Times* and with the *Daily Globe*, the *News*, the *World*, and the *Star* of Toronto. In 1892 he succeeded as leader writer on the *Globe* Edward Farrer (q.v.), for many years the ablest writer of the Canadian political press. Lewis left the *Globe* in 1903, joining the staff of the *World*, and later the *Star*, of which he was made editor in chief. He published: *British Diplomacy and Canada* (1907); *Democracy* (1908); *Life of George Brown* (1906), one of the best biographies in the "Makers of Canada Series."

LEWIS, John Frederick (1805–76). An English historical, genre, and animal painter in oil and water color. He was born in London. His first works were animal paintings, but after a journey through Germany and Italy he devoted himself to aquarelles, becoming a member of the Water-Color Society in 1829. The scope of his art was enlarged by a visit to Spain in 1832–34, during which he painted only Spanish genre. After this he resided in Paris and Rome, and in 1840 he went to Greece and Constantinople, afterward settling for 10 years in Egypt. In 1851 he returned to England, where his aquarelles were received with much enthusiasm. His "Frank Encampment in the Desert of Mount Sinai" (1842) was considered by Ruskin the finest thing of its kind since Veronese. In 1855 he was elected president of the Water-Color Society, but resigned in 1858 to devote himself to oil painting. His oil paintings, treating Oriental subjects, sustained his previous reputation, and in 1865 he was elected Academician. His paintings, especially the water colors, show brilliant though often glaring color, careful finish, and minute detail. Among his water colors are: "Halt in the Desert" (1855, South Kensington Museum); "Bull Fight at Seville" (1836); "Easter Day at Rome" (1840); the "Harem" (1851). His oils include a "Greeting in the Desert" (1856); "Door of a Café at Cairo" (1866, Royal Academy); "Edfou: Upper Egypt" (1860) and "The Courtyard of the Coptic Patriarch's House in Cairo" (1864), both in the Tate Gallery, London.

LEWIS, Matthew Gregory (1775–1818). An English romancer, nicknamed "Monk" Lewis. He was born in London, July 9, 1775. His father owned valuable estates in Jamaica. Lewis was sent to Westminster School and thence to Christ Church, Oxford. In 1792 he went to Weimar, where he saw Goethe and acquired a knowledge of contemporary German literature. In 1794 he was appointed attaché to the British Embassy at The Hague; and from 1796 to 1802 he was in Parliament. In 1798 he made the acquaintance of Sir Walter Scott, who, then unknown, was glad to contribute to his *Tales of Wonder* (1801). In 1816 he visited Byron at Geneva, and again the next year in Florence and Venice. On the death of his father (1812) he inherited the estate and slaves in the West Indies. On the homeward voyage from a second visit to Jamaica he died of yellow fever (May 14, 1818). Lewis won wide celebrity for his *Ambrosio, or the Monk* (1795), and was ever afterward known as "Monk" Lewis. It is a Gothic romance after the type of Ann Radcliffe's *Mysteries of Udolpho.* It contains, however, incidents taken from German romance, and thus becomes historically interesting as a thread connecting the literature of Germany and England. Owing to certain voluptuous passages, afterward suppressed, the sale of the book was enjoined by the Attorney-General. A Gothic melodrama entitled *The Castle Spectre,* brought out at Drury Lane in 1798, ran for 60 nights, and long continued popular. After his death appeared the *Journal of a West Indian Proprietor* (1834), which was praised by Coleridge. The *Monk* has been often reprinted, though not usually entire. A second romance, *The Bravo of Venice* (1804), is in Cassell's National Library; and *The Tales of Wonder* and the earlier *Tales of Terror* (1799) were reprinted in Morley's Universal Library (1887). Consult: *The Life and Correspondence of Lewis* (London, 1839); and for Lewis's relation to German literature, H. A. Beers, *History of English Romanticism in the Eighteenth Century* (New York, 1899); also Brandl, *S. T. Coleridge und die englische Romantik* (Berlin, 1886; trans. by Lady Eastlake, London, 1887). See ENGLISH LITERATURE.

LEWIS, MERIWETHER (1774–1809). An American explorer, born near Charlottesville, Va. He came of a well-known Virginia family, being a grandnephew of Fielding Lewis, who married a sister of George Washington, and inherited from his father a comfortable estate. At the time of the Whisky Rebellion in 1794 he gave up farming to join the forces which the government sent into western Pennsylvania, and at the close of the insurrection became an ensign in the regular army. Five years later he was promoted to the rank of captain and in 1801 became President Jefferson's private secretary. When in 1803 it was decided to send an exploring expedition into the Louisiana country, for which the United States was then negotiating with France, the President accepted the promptly offered services of his secretary. Lewis chose as his companion Capt. William Clark (q.v.), an old army friend. The party left the Mississippi in May, 1804, and proceeded up the Missouri to its headwaters, crossed the Great Divide, and, landing on one of the tributaries of the Columbia, followed it and then the Columbia to the Pacific. After a dreary winter on the coast they returned to the United States by much the same route, and reached St. Louis in September, 1806. (See LEWIS AND CLARK EXPEDITION.) As a reward for this service Congress granted Captain Lewis a tract of 1500 acres of land from the public domain, and in 1807 the President appointed him Governor of Louisiana Territory, the northern part of the Louisiana Purchase, with headquarters at the village of St. Louis. Here he soon proved himself an able administrator. In this latter work he was ably assisted by Captain Clark, who had been appointed Indian agent. His leisure moments were occupied with preparing for publication the account of his great journey; but this he was destined never to finish, for in 1809 he was called to Washington on business, and while on the way met his death mysteriously in the cabin of a Tennessee pioneer. For biographical sketches, consult the works given under LEWIS AND CLARK EXPEDITION, and *The Original Journals of the Lewis and Clark Expedition* (New York, 1905).

LEWIS, MORGAN (1754–1844). An American soldier and jurist. He was born in New York City, the son of Francis Lewis (q.v.), graduated at Princeton in 1773, and, on the eve of the Revolution, began reading law in the office of John Jay. He joined the Continental army before Boston soon after the battle of Bunker Hill, and later in the same year was commissioned major in the Second Regiment of New York militia. In 1777 he was appointed quartermaster-general of Gates's army and distinguished himself at Saratoga, and in 1779 he served with Sullivan and Clinton in the campaign in central New York. After the war he took up the practice of law, married into the Livingston family, and became prominent in Anti-Federalist politics. After a term in the Assembly and a short period on the bench of Common Pleas in Dutchess County, where he made his home, he was elected in 1791 by the council of appointment to succeed Aaron Burr as Attorney-General of the State. A year later he was appointed a judge of the New York Supreme Court, and in 1801 was made Chief Justice. In 1804 the Livingston faction secured his nomination for the office of Governor and he was elected by a large majority over Burr. He was a strong supporter of Madison's war policy, and in 1812 was offered the portfolio of War. This he declined, but almost immediately accepted the post of quartermaster-general of the army, with rank of brigadier general. On March 2, 1813, he was commissioned major general and served on the Canadian frontier, taking part in the battles of Fort George, Sacketts Harbor, and French Creek. In 1815 he resigned his commission, and the rest of his life he spent on his estates in Delaware County. For many years he was president of the New York Society of the Cincinnati, and in 1831 was elected grand master of the Freemasons. Consult *Lives of the Governors of the State of New York* (Auburn, 1851), and Delafield, *Biography of Francis and Morgan Lewis* (New York, 1878).

LEWIS, TAYLER (1802–77). An American educator and author. He was born at Northumberland, Saratoga Co., N. Y.; graduated at Union College in 1820; studied law in Albany and practiced at Fort Miller, but relinquished his profession to devote himself to classical studies. He was appointed professor of Greek at the University of New York in 1838 and at Union in 1849. He was an able and conservative Christian apologete, a prominent exponent of classical study, and a political thinker of some ability, as may be seen from his *State Rights, a Photograph from the Ruins of Ancient Greece* (1864). He was a member of the Bible Revision Committee and wrote: *The Six Days of Creation* (1855); *The Bible and Science* (1856); *The Divine Human in the Scriptures* (1860); and, with E. W. Blyden and Timothy Dwight, *The People of Africa: Their Character, Condition, and Future Prospects* (1871).

LEWIS, WILSON SEELYE (1857–1921). An American Methodist Episcopal bishop, born at Russell, N. Y. He was superintendent of public schools at Belle Plaine, Ia., from 1882 to 1885; entered the ministry, joining the Upper Iowa conference of his church in 1885; and was principal of the Epworth Seminary from 1888 to 1897. In 1889 he received the degree of A.B. from Cornell College (Iowa) and in 1892 that of A.M. From 1897 to his election as Bishop in 1908 he was president of Morningside College, Sioux City, Ia. After his election he served as resident Bishop at Foochow, China, sharing with Bishop J. W. Bashford the oversight of all the missionary conferences of China.

LEWIS AND CLARK CENTENNIAL EXPOSITION. This exposition, which had for its object the celebration of the one hundredth anniversary of the exploration of the Oregon country (comprising the present states of Oregon, Washington, Idaho, and parts of Montana and Wyoming), was held in Portland, Oreg., from June 1 to Oct. 15, 1905. The site, consisting of 385 acres of land and lake, nestled at the base of the foothills of the Cascade Range, overlooking Guild's lake and the Willamette River, with a view embracing the snow-capped peaks of Mount Hood and Mount St. Helens, and was within easy reach of Portland by boat or street car. Ten large exhibit palaces formed the nucleus of the Exposition. Around these were clustered the State and Concessions buildings, special pavilions, the Administration group, the Auditorium, and other smaller exhibit buildings. The main exhibit palaces were, with the exception of the Forestry Building, in the Spanish Renaissance style of architecture and included the following: Agriculture; Liberal and Industrial Arts; Foreign Exhibits; Forestry; Horticulture; Mines and Metallurgy, United States Government Exhibit Building; Oceanic Building; United States Fisheries, Forestry, and Irrigation Building; Machinery, Electricity, and Transportation. The amusement features were grouped in a street on the west side of the grounds, which was called "The Trail." The Exposition was opened with appropriate ceremonies, and President Roosevelt touched the button in the White House that inaugurated the event. The cost of the Exposition was estimated at about $7,000,000, and at its close, after settling all bills, it was announced that a cash balance would be available to distribute among the subscribers to the stock. The grand total attendance was 2,545,509, of which 56,960 was on the last day and 56,000 on July 4.

LEWIS AND CLARK EXPEDITION. In American history, an expedition, under the command of Meriwether Lewis (q.v.) and William Clark (q.v.), which in 1804–06 penetrated from the Mississippi River, through territory now forming parts of Missouri, Kansas, Nebraska, South Dakota, North Dakota, Montana, Idaho, Washington, and Oregon, to the Pacific Ocean. The members of the party were the first white men to cross the continent between the Spanish possessions to the south and the British possessions to the north. The expedition was sent out by President Jefferson for the purpose of exploring the Louisiana Territory immediately after its purchase from France. As at first organized the party consisted of 29 members: Lewis and Clark, 14 regular United States soldiers, 9 Kentuckians who had volunteered, 2 French watermen, an interpreter and hunter, and a negro servant. At St. Louis 16 additional men were enlisted for the enterprise, to go, however, only part of the way. The party started from the vicinity of St. Louis, Mo., on May 14, 1804; passed up the Missouri River; reached the mouth of the Platte on July 26; arrived at the camps of the Mandans and Minnetarees, about 1600 miles distant from St. Louis, late in October; wintered there; broke up winter quarters April 7, 1805, 14 men having been sent back to St. Louis with collections and reports and two recruits having been gained; reached the mouth of the Yellowstone River April 26; and on May 26 sighted the Rocky Mountains. The three forks of the Missouri River were discovered on July 25 and named Jefferson, Madison, and Gallatin. The party proceeded up the Jefferson; crossed the Rocky Mountains in September; started down the Columbia River on October 16; and on November 7 came in sight of the Pacific Ocean. After wintering on the coast, they started on their return, March 23, 1806, and arrived at St. Louis Sept. 23, 1806, having traveled altogether a distance of almost 8500 miles. At times the explorers suffered terrible hardships, and from April, 1805, to August, 1806, were shut off from all communication with the world. Lewis and Clark collected a mass of valuable information concerning the physical characteristics, the fauna and flora, the climate, and the various Indian tribes of the territory traversed. The expedition was commemorated by Lewis and Clark Centennial Exposition at Portland, Oreg., in 1905 (q.v.).

Bibliography. For the best accounts, consult: Jefferson, *Message from the President of the United States, Communicating Discoveries Made in Exploring the Missouri, Red River, and Washita by Captains Lewis and Clark, Dr. Sibley, and Mr. Dunbar* (Washington, 1806; various subsequent editions); Gass, *A Journal of the Voyages and Travels of a Corps of Discovery under the Command of Captain Lewis and Captain Clark* (Pittsburgh, 1807; several subsequent editions); and especially Allen (Biddle ed.), *History of the Expedition under the Command of Captains Lewis and Clark* (2 vols., Philadelphia, 1814), which is based on the journals kept by Lewis and Clark themselves and has been frequently reprinted. The journals themselves have been edited by R. G. Thwaites (8 vols., New York, 1904–05). Consult also: N. Brooks, *First Across the Continent: Expedition of Lewis and Clark* (New York, 1901); a brief sketch by W. R. Leighton, *Lewis and Clark* (Boston, 1901); O. D. Wheeler, *The Trail of Lewis and Clark* (2 vols., New York, 1904).

LEWISBURG, lū′ĭs-bûrg. A borough and the county seat of Union Co., Pa., 30 miles by rail south by east of Williamsport, on the west branch of the Susquehanna River, and on the Pennsylvania and the Philadelphia and Reading railroads (Map: Pennsylvania, H 5). It is the seat of Bucknell University (Baptist), opened in 1846, and contains a public library. The borough is the commercial centre for a fertile grain and general farming region, and has woolen, flour, knitting, and lumber mills, furniture and chair factory, machine shop, acetylene-gas works, a shirt factory, a brick kiln, a milk condensery, etc. Pop., 1900, 3457; 1910, 3081.

LEWISOHN, lū′ĭ-zōn, ADOLPH (1849–). An American capitalist, born at Hamburg, Germany. Coming to the United States, he became president of the United Metals Selling Company and of the General Development Company, vice president of the Utah Consolidated Mining Company, and director of other corporations. By appointment of President Taft he was a member of the Commission on Industrial Relations in 1912. He made a number of large benefactions, including $300,000 to Columbia University for a School of Mines Building; $100,000 to Yale University; a German library and a stadium (1914) to the

College of the City of New York; and numerous gifts to Jewish charities.

LEWISOHN, Ludwig (1882–). An American writer and Germanic scholar. Born in Berlin, Germany, he was brought to the United States in 1890, and he graduated from the College of Charleston, S. C., in 1901, and from Columbia University (A.M.) in 1903. He worked on the editorial staff of Doubleday, Page & Co. in 1904–05 and wrote stories, poems, and criticism for various magazines in 1905–10. He was an instructor in German at the University of Wisconsin in 1910–11 and then became assistant professor of the German language and literature at Ohio State University. He was translator of Feuchtersleben's *Health and Suggestion* (1910) and Suderman's *Indian Lily* (1911); editor and chief translator of the *Dramatic Works of Gerhart Hauptmann* (vol. i, 1912; vol. v, 1915); and author of *The Broken Snare* (1908); *A Night in Alexandria* (1909); *German Style, An Introduction to the Study of German Prose* (1910); *The Modern Drama* (1914).

LEW'ISTON. A city and the county seat of Nez Perce Co., Idaho, located at the junction of the Snake and Clearwater rivers, 147 miles south by west of Spokane, Wash., on the Northern Pacific and the Oregon-Washington Railroad and Navigation lines (Map: Idaho, A 3). It has a Carnegie library, St. Joseph's Hospital, high school, United States Weather Bureau station, and Supreme Court library; and is the seat of a State normal school. Lewiston is the centre of a great mining, wheat and fruit growing district, and has flour and box-making mills. There are also dairying and stock-raising interests. The city was incorporated in 1890 and has adopted the commission form of government. The water works are owned by the municipality. Pop., 1900, 2425; 1910, 6043.

LEWISTON. A city in Androscoggin Co., Me., 35 miles by rail north of Portland, on the east bank of the Androscoggin River, opposite Auburn, on the Grand Trunk system, and on three branches of the Maine Central Railroad (Map: Maine, B 4). Several bridges here span the river. The stream at this point falls 50 feet, affording fine water power, which is utilized by means of a distributing dam and canal, the system having been built at a cost of $1,000,000 and having a developed power of 30,000 horse. It is the most important industrial city in Maine, the manufactures including cotton and woolen goods, cotton and woolen mill machinery, foundry products, boots and shoes, belting, lumber products, carriages, shirts, iron beds, bobbins, shovel handles, and bricks. There are also extensive bleaching and dye works. Lewiston is the seat of Bates College (q.v.), and has a fine city hall, a public park, the General and St. Mary's hospitals; a fine soldiers' monument, erected in the city park in 1865; homes for aged women and children; the Healy Orphan Asylum; Elks and Moose homes; the Manufacturers and Mechanics' Library, affiliated with the Carnegie library, and the collegiate library. There are municipally owned water works and electric-light plant. Pop., 1900, 23,761; 1910, 26,247; 1914 (U. S. est.), 27,305; 1920, 31,791. Settled in 1770 and called the "Plantation of Lewiston" until 1795, when it was incorporated as a town, Lewiston was chartered as a city in 1861.

LEWISTON. A village and summer resort in Niagara Co., N. Y., on the Niagara River, 7 miles north of Niagara Falls; the terminus of a line of steamers to Toronto; on the New York Central and Hudson River Railroad (Map: New York, A 4). It has a public library. The Gorge Road, the Lewiston and Queenstown Bridge, and the Tuscarora Indian Reservation are of interest in this locality. Pop., 1910, 713. A blockhouse was erected here by the French in 1720, but was soon abandoned, though an Indian village, later the home of Joseph Brant, grew up in the vicinity. Near it are Devil's Hole and Bloody Run—the scene of a terrible Indian massacre on Sept. 14, 1763. In 1813 (December 19) Lewiston was burned by the English and Indians. Consult Pool, *Landmarks of Niagara County, N. Y.* (Syracuse, 1897).

LEW'ISTOWN. A city and the county seat of Fulton Co., Ill., 45 miles southwest of Peoria, on the Chicago, Burlington, and Quincy Railroad (Map: Illinois, D 5). The city has a Carnegie library. It carries on considerable trade in live stock and agricultural and dairy products; and manufactures bee traps, cigars, concrete blocks, etc. The water works are owned by the city. Pop., 1900, 2504; 1910, 2312.

LEWISTOWN. A city and the county seat of Fergus Co., Mont., 118 miles by rail east-southeast of Great Falls, on the Great Northern and the Chicago, Milwaukee, and St. Paul railroads, and on Spring Creek, which affords excellent water power (Map: Montana, G 2). The city contains a fine high school, the Catholic Hospital, and a Carnegie library. Its chief industries are gold and coal mining, wheat growing, and the manufacture of bricks, flour, and creamery products. The city is progressing rapidly as the distributing centre for a wide area. Lewistown owns its water works. Pop., 1900, 1096; 1910, 2992.

LEWISTOWN. A borough and the county seat of Mifflin Co., Pa., 61 miles by rail northwest of Harrisburg, on the Juniata River and on the Pennsylvania Railroad (Map: Pennsylvania, F 6). It is in a fertile farming district which has mineral deposits, particularly of iron and glass sand; and there are foundries, furnaces, steel works, flour and lumber mills, a silk mill, and manufactories of edge tools, hosiery, etc. The borough contains a hospital and a public library. Pop., 1900, 4451; 1910, 8166; 1914 (U. S. est.), 9748.

LEWIS-WITH-HARRIS. A Scottish island, the northernmost of the outer Hebrides (q.v.), 30 miles northwest of Ross-shire, from which it is separated by the Minch (Map: Scotland, B 1). Area, 770 square miles. Pop., 1901, 32,160; 1911, 32,886. The coasts are wild and rugged: the chief indentations are Broad Bay and Lochs Erisort, Seaforth, Resort, and Roag. The surface is for a considerable portion swampy and covered with peat. Barley and potatoes are the principal crops raised. The inhabitants are of Celtic extraction, with the exception of a colony in the north, who, although they speak the Gaelic language, are of Scandinavian descent. The chief industries of the island are cattle raising and sheep farming, while Harris is famous for its homespun tweeds. Relics of antiquity and remains of ancient forests abound. At Callernish exists the most perfect Druidical stone circle found anywhere in the British Isles. Carloway, on the west coast, has important sea fisheries, while the island is famous for its salmon, trout, and abundance of feathered game. Stornoway (q.v.), on the east coast, is the capital town.

LEX (Lat., law). The ancient Latin term for a statute. In its widest sense it covered any enactment of any body constitutionally empowered to legislate; used more strictly the term denoted rather the enactments of the *comitia centuriata*. See Comitia; Legislation. For a full list of the more important *leges*, consult the article "Lex" in William Smith, *A Dictionary of Greek and Roman Antiquities*, vol. ii (3d ed., London, 1891).

LEX AGRARIA. See Agrarian Laws.

LEX CURIATA. See Comitia; Emperor; Imperium.

LEX FO′RI (Lat., the law of the forum). The law administered in the jurisdiction in which cause is pending for determination. Ordinarily, of course, a court applies its own law, i.e., the law of the state or country in which it exercises its jurisdiction, but in certain cases it applies foreign law, as the law of the state or country in which a contract was made (*lex loci contractus*), or in which property involved in the suit is situated (*lex loci rei sitæ*). See Conflict of Laws; Forum.

LEX HORTENSIA. See the first Hortensius, Quintus.

LEXICOG′RAPHY. See Dictionary.

LEX′ICON. See Dictionary.

LEX′INGTON. A city and the county seat of Fayette Co., Ky., 82 miles south of Cincinnati, Ohio, on the Cincinnati, New Orleans, and Texas Pacific, the Chesapeake and Ohio, the Louisville and Nashville, and the Southern railroads (Map: Kentucky, F 3). It is the centre of the widely celebrated blue-grass region, is well laid out, and has a Carnegie library, a State asylum for the insane, Kentucky Reform School, Kentucky State University, Sayre Female Institute, Hamilton Female College, Transylvania University, St. Catherine's Academy (Roman Catholic), Knights of Pythias and Odd Fellows widows' and orphans' homes, Good Samaritan and St. Joseph hospitals, and High Oaks Sanitarium. Other places of interest are Woodland Park, the race tracks, United States Weather Bureau station, and several noted stock farms. Lexington is commercially important as the market for the blue-grass district and is well known also for the manufacture of Bourbon whisky, which, in addition to horses and tobacco, it exports in large quantities. Other manufactures are flour, saddlery and harness, carriages and wagons, canned goods, hemp, parquetry flooring, and brewery, planing-mill, foundry, and machineshop products. Lexington adopted the commission form of government in 1912. Pop., 1900, 26,369; 1910, 35,099; 1914, 38,819; 1920, 41,534.

In 1775 several hunters, including Robert Patterson, Simon Kenton, and William McConnell, stopped on the site of Lexington, gave it its present name to commemorate the battle of Lexington, and built a cabin to confirm their title to the land. A permanent settlement was made by Patterson four years later. In 1782 the town was incorporated by the Virginia Legislature. From 1792 to 1793 it was the capital of Kentucky and here, in 1792, assembled the first State Legislature. In 1832 a city charter was obtained. It was the home from 1797 until his death of Henry Clay, in memory of whom a fine monument has been erected. There are also monuments to John C. Breckinridge and John H. Morgan.

LEXINGTON. A town in Middlesex Co., Mass., 12 miles northwest of Boston, on the Boston and Maine Railroad (Map: Massachusetts, E 3). Among the points of interest are Memorial Hall, with fine marble statues of John Hancock and Samuel Adams; Cary Memorial Library, containing 25,000 volumes; a statue of Captain Parker; the battle ground; the Soldiers' Monument, erected in 1799; the Hancock-Clarke house (built in part in 1698), where Hancock and Samuel Adams slept the night before the battle of 1775, and now the repository of an interesting collection of relics; Monroe Tavern (built in 1695), Earl Percy's headquarters; Buckman Tavern (built about 1690), the rendezvous of the minutemen; the old Belfry clubhouse; the town hall; the high school; the Hancock schoolhouse; and the old burying ground. The leading industries are farming and dairying and the manufacture of pipe fittings and leather binding. Pop., 1910, 4918. Settled in or about 1642, Lexington was a part of Cambridge and was known as "Cambridge Farms" until 1691, when it was made into a separate precinct and given its present name probably from Lord Lexington. It was incorporated as a town in 1713. It was the birthplace of Theodore Parker.

Lexington is celebrated in American history for having been the scene of the first contest in the Revolutionary War, fought April 19, 1775. On the night of April 18 the Americans discovered the intention of General Gage to send a detachment of British troops to Concord for the purpose of destroying some military stores which had been collected there, and also to seize the persons of John Hancock and Samuel Adams, who were living temporarily in Lexington. Information of this design was spread abroad by Paul Revere, who rode from Charlestown to Lexington warning farmers along the route. On the same evening General Gage, who commanded the royal troops in Boston, had picketed the roads in the vicinity and dispatched Lieutenant Colonel Smith with 800 men on the expedition to Concord. When the advance of the British column reached Lexington in the early morning it was opposed by about 70 militiamen, who had formed on the town common, under command of Capt. John Parker. The British were commanded by Major Pitcairn, who, on observing the preparations made to resist his progress, halted his men to load, and then advanced at double-quick, he himself riding in front and ordering the Americans to lay down their arms and retire. As the militia held their ground, Major Pitcairn fired his pistol at them, and having given the order to his men, the latter discharged their muskets, with the result of killing four and wounding nine of the militiamen. The latter retreated, four being killed while fleeing. A scattering fire from Captain Parker's men wounded three British soldiers, and the militia being dispersed, the British force proceeded to Concord to effect the main object of the expedition. The distance is only about 6 miles, and the place, which became the second battleground of that day, was reached at about 7.30 o'clock. The country was by this time thoroughly aroused, and as many as 180 militiamen had assembled, who, as the British came into view, fell back and took position on the side of a hill, afterward crossing the North Bridge over the Concord River by order of Colonel Barrett, who had assumed command. The British, being left in possession of the town, proceeded to the destruction of such arms and provisions as they could find, a detachment being sent to gain control of the North and South bridges. This body was attacked by the militia at the North Bridge, and a brisk fight followed, which resulted in slight losses on both sides. The British, having effected all the damage possible, began to retreat, being followed by the Americans, who kept up a galling fire from behind rocks, trees, and other defenses. The timely arrival of a large force under Lord Percy prevented a disaster. The news of these encounters thrilled the country and impressed the Americans with a sense of their own capability to contend with the tried regulars of the British army. The British losses for the entire day were 73 killed, 174 wounded, and 26 missing; the American losses were 49 killed, 39 wounded, and 5 missing. Consult: Charles Hudson, *History of the Town of Lexington* (Boston, 1868), revised and continued to 1912 by the Lexington Historical Society; W. D. Howells, *Three Villages* (Boston, 1884); Richard Frothingham, *History of the Siege of Boston and of the Battles of Lexington, Concord, and Bunker Hill* (Boston, 1873); *Proceedings of the Lexington Historical Society and Papers Relating to the Town* (Lexington, 1890–).

LEXINGTON. A city and the county seat of Lafayette Co., Mo., 43 miles by rail east of Kansas City, on the south bank of the Missouri River and on the Missouri Pacific Railroad (Map: Missouri, C 2). It has the Wentworth Military Academy, Central College for Women, and Lexington Female College. The city is the centre of a corn-growing region, and coal is mined in the vicinity and shipped extensively. The government is administered under statutory provisions, by a mayor, elected biennially, and a unicameral council. Lexington was settled in 1821 and incorporated about nine years later. Pop., 1900, 4190; 1910, 5242. There is a hill to the northeast of the city, where in September, 1861, 3000 Union soldiers, under Col. James Mulligan, sustained a siege against 12,000 Confederates under Gen. Sterling Price, at last surrendering the town and garrison on the 21st. A few days later Price withdrew, leaving only a small garrison, and on October 16 a Union force of about 230 under Major J. White released the Union prisoners here and captured about 70 of the Confederates.

LEXINGTON. A city and the county seat of Davidson Co., N. C., 88 miles (direct) west of Raleigh, on the Southern and the Winston-Salem Southbound railroads (Map: North Carolina, B 2). The chief industrial establishments are woodworking plants and cotton mills. Situated in a rich agricultural region, Lexington produces cotton, tobacco, wheat, oats, and corn. The water works and electric-light plant are owned by the city. Pop., 1900, 1234; 1910, 4163.

LEXINGTON. A town and the county seat of Rockbridge Co., Va., about 50 miles by rail northwest of Lynchburg, on the north fork of the James River and on the Chesapeake and Ohio and the Baltimore and Ohio railroads (Map: Virginia, E 4). It has picturesque surroundings and is the centre of a fertile agricultural, fruit-growing, and stock-raising region. There are some manufactures. The town is the seat of Washington and Lee University (q.v.), and of the Virginia Military Institute, founded in 1839. Other features of special interest are the statues of Generals Lee and Jackson, whose graves are also here, Lee Memorial Church, and Jackson Memorial Hospital. The famous Natural Bridge (q.v.) is 14 miles south, and in the opposite direction are several mineral springs which have become popular resorts. Lexington owns and operates its water works. Pop., 1900, 3203; 1910, 2931.

LEX'IS, Wilhelm (1837–1914). A German economist, born at Eschweiler, near Aix-la-Chapelle. He studied mathematics and natural science at the University of Bonn and in 1861 went to Paris, where the economics of France chiefly claimed his attention. He was appointed professor of political economy at the University of Strassburg in 1872 and accepted a call to the chair in the same branch at Dorpat in 1874, at Freiburg in 1876, at Breslau in 1884, and at Göttingen in 1887. A partial list of his writings includes: *Einleitung in die Theorie der Bevölkerungsstatistik* (1875); *Zur Theorie der Massenerscheinungen in der menschlichen Gesellschaft* (1877); *Die Wirkung der Getreidezölle* (1889); *Der gegenwärtige Stand der Währungsfrage* (1896); *Die neuen französischen Universitäten* (1901); *Reform des höheren Schulwesens in Preussen* (1902); *Abhandlung zur Theorie der Bevölkungs- und Moralstatistik* (1903); *Unterrichtswesen im Deutschen Reich* (4 vols., 1904); *Das Handelswesen* (2d ed., 1912); *Allgemeine Volkswirtschaftslehre* (2d ed., 1913). With Conrad, Elster, and Löning, he edited the *Jahrbuch für National-Oekonomie* (after 1891) and the *Handwörterbuch der Staatswissenschaften* (7 vols., 2d ed., 1898–1901).

LEX JU'LIA MUNICIPA'LIS. See Heraclea, 1.

LEX LOCI. See Lex Fori; Conflict of Laws.

LEX MUNICIPA'LIS. See Municipal Law.

LEXOW, lĕks'ou, Clarence (1852–1910). An American legislator and municipal investigator, born in Brooklyn, N. Y. He graduated from Columbia Law School in 1874 and studied later at the University of Jena. As a lawyer, he settled in New York City, and helped establish the firm of Lexow, Mackellar, and Wells, which received the patronage especially of German-Americans. While residing in Nyack, he became active in politics as a Republican and was an unsuccessful nominee for Congress in 1890. When elected a member of the New York State Senate in 1893 he immediately became a leader. His resolution calling for an investigation of the New York City police led to the creation of the famous Lexow Committee of which he was chairman. The committee's report revealed a system of protection given to vice and resulted in many important reforms. As chairman of committees investigating trusts and on primary election reform Lexow presented findings that were embodied in several important statutes, and he was the author of the bill creating the city of Greater New York. He introduced the gold plank in the platform of the Republican State Convention of 1896 and was a presidential elector in 1900. Consult the official reports of his committees on the New York police (5 vols., 1895) and on the trusts (1897).

LEYBACH, lī'bäg, Ignace Xavier Joseph (1817–91). A French composer, born at Gambsheim (Alsace). He began his musical studies in Strassburg and later went to Paris, where he was a pupil of Kalkbrenner, Pixis, and Chopin. In 1844 he was appointed organist of the cathedral in Toulouse. He wrote more than 200 compositions for the pianoforte, which enjoyed an enormous popularity because of their ingratiating melody and facility of execution. His great organ school in three volumes, *L'Organiste pratique*, is a work of considerable merit.

LEYDEN, or **LEIDEN**, lī′dĕn. One of the oldest and most famous cities of the Netherlands, situated in the Province of South Holland, on the Old Rhine, 22 miles southwest of Amsterdam and 6 miles inland (Map: Netherlands, C 2). On the east the river enters in two branches, which unite in the centre of the town, which is also traversed by several small canals. Of its churches the most noteworthy are St. Pancras (Hooglandsche Kerk), a fine late Gothic building originally erected in the fifteenth century and restored in 1885–1902, and the church of St. Peter, dating from 1315. Both churches contain monuments to distinguished scholars. The sixteenth-century town hall in Dutch style, and the Lakenhal (cloth hall), dating from 1640 and housing the Municipal Museum (founded in 1869), are among the prominent secular buildings. On an elevation in the centre of the town are the ruins of the old Burg. Besides its university (see Leyden, University of), to which it chiefly owes its fame, Leyden has a Gymnasium, two other high schools, and a navigation school. Leyden was the birthplace of Rembrandt, Gabriel Metsu, Gerard Dou, Jan Steen, and other celebrated painters. In the fifteenth century its textiles were famous throughout Europe. The chief manufactures are various woolen products, cotton goods, leather, iron products, and spirits. There is a considerable trade in local manufactures and dairy products. The population of Leyden is believed to have been about 100,000 in the seventeenth century. In 1900 the population of the commune was 54,421; in 1909 (census of December 31), 58,253; in 1912 (est. of December 31), 59,207. The area of the commune is 565 hectares.

The most brilliant event in the history of Leyden was its heroic defense against the Spaniards, who besieged the city for a whole year —1573–74. The citizens withstood the siege almost to the last point of endurance, when William of Orange at last relieved them by opening the dikes and flooding the country. From 1609 to 1620 Leyden was the place of refuge of a band of English Nonconformists from whom came the Pilgrims who founded Plymouth Colony. In 1807 a large section of the most beautiful quarter of the city was laid in ruins by the explosion of a powder ship in the river. This part is now occupied by a park.

LEYDEN, Ernst von (1832–1910). A German physician, born at Danzig and educated in Berlin at the Friedrich Wilhelm Institute. From 1854 to 1865 he served as military surgeon, then became professor at Königsberg, in 1872 went to Strassburg, and in 1876 succeeded Traube in Berlin. He retired in 1907. His publications include: *Zur Pathologie des Tetanus* (1863); *Ueber Reflexlähmungen* (1870); his great work *Klinik der Rückenmarkskrankheiten* (1874–76); *Tuberkulosis* (1902); and many contributions to the *Zeitschrift für klinische Medizin*, which he founded in 1879 with Frerichs. His *Lebenserrinerungen*, compiled by his sister, appeared in 1910.

LEYDEN, John (1775–1811). A Scottish poet and Orientalist. He was born of poor parents at Denholm in Roxburghshire, Scotland, Sept. 8, 1775. After a course of study in Edinburgh University, during which he learned several European and Oriental languages, he was licensed as a preacher of the Church of Scotland. His first work (1799) was *A Historical Account of the Discoveries and Settlements of Europeans in Northern and Western Africa*, suggested by the travels of Mungo Park. He contributed poems and translations to the *Edinburgh Magazine*, wrote for Lewis's *Tales of Wonder*, helped Scott to get materials for his *Minstrelsy of the Scottish Border*, and edited the *Scots Magazine* for a year. In 1801 he edited the *Complaynt of Scotland*, a sixteenth-century work, which aroused some interest at the time. He then studied medicine, and sailed for India in 1802. Ill health forced him to leave his station at Madras and go to Penang, where he studied the Indo-Chinese tribes. He was successively professor and judge at Calcutta. When the expedition to Java was undertaken, Leyden accompanied it. A second edition of his *Scenes of Infancy: A description of Teviotdale*, a poem, was issued at Edinburgh within the year of his death. He died at Batavia, Aug. 28, 1811. His chief work is the "Essay on the Languages and Literatures of the Indo-Chinese Nations," in the *Asiatic Researches*. His collected poems were published in 1819; a new edition, *Poems and Ballads*, in 1858, with memoir by Scott; and two centenary editions in 1875.

LEYDEN, John of. See John of Leyden.

LEYDEN, Lucas van. See Lucas van Leyden.

LEYDEN, University of. A Dutch university, founded in 1575 by the provinces of Holland and Zealand, under the patronage of William the Silent, Prince of Orange, as one of the rewards to the citizens of Leyden for the heroic defense of the place against the Spaniards. From the beginning it was a centre of Protestant learning, and drew to itself many English Puritans and French Huguenots. In 1807 it was raised to the rank of a royal university, but with the annexation of Holland to France it sank to the grade of an academy, forming part of the University of France. After the reorganization of the universities by William I, in 1815, it lost ground, but was again reorganized in 1878 on an equality with the royal universities. It numbered in 1912–13 some 1211 students, chiefly in law and medicine. Its library, founded in 1575, contains some 400,000 volumes, 3000 maps, 3400 Oriental and 3000 other manuscripts.

LEYDEN JAR. See Electricity; Condenser.

LEYDIG, lī′dĭk, Franz von (1821–1908). A German zoölogist, born at Rothenburg-an-der Tauber. He studied medicine at Würzburg and Munich, became professor at Würzburg in 1855, at Tübingen in 1857 and in 1875 at Bonn, and retired in 1895. His more important works include: *Anatomisch-histologische Untersuchungen über Fische und Reptilien* (1853); *Der Eierstock und die Samentasche der Insekten* (1866); *Die augenähnlichen Organe der Fische* (1881), on a supposed sixth sense; *Zelle und Gewebe* (1885); *Horæ zoölogicæ: Zur vaterlandischen Naturkunde* (1902).

LEYE. See Lys.

LEYLAND, John. See Leland, John.

LEYS, līs *or* lā, Hendrik, Baron (1815–69). A Belgian historical and genre painter. He was born at Antwerp, Feb. 18, 1815, and studied with Ferdinand de Braekeleer, his brother-in-law, and later with Wappers, at the Antwerp Academy. He received the great gold medal at the Brussels Academy in 1835; the next four years he studied in Paris. There he was strongly influenced by the French Romanticists, although some of his work of the same period shows also the influence of Rembrandt and Van Dyck. In 1839 he visited Holland, where he took up the manner of the Dutch genre painters. His "Dutch Church Service," "Dutch Society of the Seventeenth Century," both in the National Gallery, Berlin, and "Wedding of the Seventeenth Century" (1845) contain such rich details, both in costume, decoration, and treatment of draperies, as are found in a Pieter de Hoogh or a Metsu. The years 1852, 1859, 1863, he spent in Germany; and during the time he was strongly influenced by Dürer and Cranach. To this period belong "Erasmus in his Study" (1853), "Luther as Chorister in Eisenach," "Luther's Home in Wittenberg" (1858). He was the recipient of great gold medals at Paris in 1855 and 1867 and many other honors, and his death, August 26, 1869, was marked by universal mourning in Antwerp. A statue was erected to his memory on the Boulevard Leys.

To Leys is largely due the revival of a national art in Belgium by the return to the ideals of the old Flemish and Dutch masters. He was a fine colorist and a good draftsman, in his first style showing delight in careful detail, while in his second style his work is as severe in outline as the paintings of the fifteenth and sixteenth centuries, with the simplicity of the early Flemish and German masters, even to their faults in drawing. Among his most important works are the following: "The Institution of the Golden Fleece" (King of the Belgians); "The Flemish Wedding" (1859) and "Mass is Over" (1866), in the Antwerp Gallery; "Mass in Honor of Bertall de Haze" (1854) and the "Spanish Fury," Museum of Brussels; "Lucas Cranach Painting Luther" (1863) and "The Education of Charles V" (1861), in the Vanderbilt collection, Metropolitan Museum, New York; "Edict of Charles V" and "Dutch Interior," Walters Gallery, Baltimore; "Rembrandt's Studio" (1837); "Restoration of Divine Service in Antwerp Cathedral" (1845); "Studio of Frans Hals" (1868); "Dürer Painting Erasmus" (1857), Berlin Museum; four scenes from the history of Antwerp and portraits of 12 princes celebrated in connection with the city (1864–69), City Hall, Antwerp. Consult Sulzberger, *Henri Leys* (Brussels, 1835), and A. L. C. Lemonnier, *Ecole belge de peinture* (ib., 1906).

LEYTE, lā′tȧ. An island of the Visaya group in the Philippines, constituting with a number of small dependent islands the Province of Leyte (Map: Philippine Islands, E 5). It is situated to the southeast of Luzon and is separated from the island of Samar on the northeast by the Strait of San Juanico, from 1 to 3 miles wide, and from Mindanao on the southeast by the Strait of Surigao (q.v.). The principal dependent islands are Biliran, 16 miles long by 13 broad (area, 144 square miles), off the north coast; Panaón, 19 miles long by 6 broad (area, 76 square miles), off the southeast coast; and the Camotes, a group of three islands 20 miles from the west coast. The island of Leyte has an extreme length from northwest to southeast of 121 miles and an extreme width of 52 miles. Its area is 3872 square miles; with the dependent islands, 4214 square miles. It has a roughly rectangular shape, with a large bay indenting each of the four sides, and a number of smaller inlets forming in several places excellent harbors, such as that of Tacloban (q.v.). The coasts are, as a rule, clear, with deep water close inshore, except along the northwestern end, where there are reefs and shoals. The east coast is high and steep; the west low and sandy, interrupted by a number of rocky headlands. The interior is generally mountainous; an irregular chain with a number of peaks runs parallel with the west coast, about 6 miles inland, and reaches in Mount Sacripante a height of 3930 feet. There are several extinct volcanoes, some of which are over 4000 feet high. The rivers of Leyte are numerous, but are, as a rule, small mountain torrents. The chief among them are the Bao and the Leyte, both in the northwest. There is only one considerable lake, the Laguna de Bito, 5 miles long by 3 broad, situated near the centre of the island.

The climate is temperate and healthful; the extreme annual temperatures are 52° F. lowest and 86° F. highest. The island is abundantly watered and very fertile. Large parts of it are covered with forests, in which one of the predominant species is the Dammar pine, from which great quantities of pitch are produced; these forests also yield some of the finest hard woods of the archipelago. The numerous broad valleys are among the best-cultivated lands of the Philippines and yield abundant crops of hemp of an excellent quality, besides sugar, rice, coffee, cotton, and corn. The island produced, in 1902, 10,116,044 kilograms of manila hemp, or more than any island in the Philippine group except Luzon. Leyte also ranked second in production of bananas and third in the production of copra. The mineral wealth of Leyte includes gold, silver, iron, lead, and sulphur, only the last mentioned being mined to any extent. The leading industries consist in the manufacture of hempen fabrics and coconut oil. Shipbuilding is also an important industry, the shipyards of Tacloban employing several hundred persons. The population numbered, in 1903, 357,641, almost all of whom are Visayans, speaking the Visayan language. They are intelligent and industrious and show great interest in American institutions. The census of 1903 classes the entire population as civilized. Of the 250,000 above 10 years of age 51,000 were classed as literate and 55,100 able to read but not write. The school attendance in 1903 was reported as 45,393.

Leyte was first seen by Magellan in 1521. Its original name was Abuyog, and the Spaniards called it first Filipina, which name was later extended to the whole archipelago. Civil government under American rule was instituted on April 22, 1901, and the inhabitants showed such a friendly attitude towards the new régime that before the end of the year most of the island was intrusted to the native constabulary.

LEYTON, lā′ton, or Low Leyton. A town in Essex, England, a London suburb, 5½ miles northeast of St. Paul's (Map: London, D 8). It owns an electric-light plant, an economical and efficient sewerage system, free libraries, a fine technical institute, opened in 1896, and an isolation hospital. Leyton is mainly a residential suburb and has little or no manufacturing industries. Roman remains have been found here. Pop., 1901, 98,900; 1911, 124,735.

LHASA, lä′sȧ, **LASSA**, or **H'LASA** (Tibetan

Lhā-Sā, God's place or house; in Chinese, *Fŏ-fi*, Buddha land). The capital of Tibet, and the chief seat of the Lamaistic hierarchy, situated on the right or north bank of the Kyi-ch'u, a left-bank tributary of the Tsangpo or Brahmaputra River, in an elevated plain (12,500 feet above sea level), sometimes called Wo-ma-t'ang (milk plain), sloping to the north for about 12 miles and surrounded by lofty, barren mountains 3000–6000 feet higher (Map: China, F 5). The city is small, about 2 miles long and 1 mile wide, but regularly laid out; the principal streets are wide, well lined with Tibetan, Chinese, and Nepalese shops. There is no wall around the city; a broad highway encircles it instead. The whole town when seen by the British in 1904 was exceedingly filthy. The principal buildings are of stone, two or three stories high, but there are many of adobe and sun-dried brick. Outside they are clean and whitewashed, inside very dark and filthy. The first floor always has a yak stable. The houses have flat roofs and no chimneys. The chief trade is in precious stones, gold, velvet, cashmere, and other fabrics peculiar to the region; and in tea from China, silk, lace, carpets, Russian goods, musk, etc. There is little traffic on the streets. Carts are unknown. People always travel on foot. Only the Dalai Lama and the two Ambans ride in sedan chairs, a privilege reserved to them exclusively. The chief interests of the city, however, are religious; thousands of pilgrims visit it annually from Mongolia, Kashmir, Nepal, etc., and Buddhist temples and monasteries abound. Near its centre stands the cathedral, a lofty, flat-roofed shrine, resplendent with green and gold, known as the Jo-K'ang or Lha-K'ang (the house of the Lord), surrounded with conventual houses and gardens. Here stands a life-size image of Buddha as a prince, about 16 years of age, said to have been cast during his lifetime in Magadha, the Buddhist Holy Land.

In the suburbs to the west of the city is the fortified palace of the Dalai Lama, the head of the Lamaist church, and the incarnation of Avalokiteshvara (see KWAN-YIN), an imposing pile of lofty buildings, entirely of stone, with 490 rooms and 1333 windows. The palace is painted in white, brown, and crimson. Inside it is dirty, the only clean part being the rooms of the Dalai Lama. It is perched on the rocky hill, called by its founder Mount Potala, which rises from the plain to a height of 375 feet. A replica of the palace was erected in Jehol (q.v.), in east Mongolia, by the Emperor K'ien-lung. These buildings date from 1643 and are well described by Huc and Gabet, Waddell, Landon, and others. To the south of this, also on a rocky hill, is the pavilion used by the Tashi Lama, of the Tashilhumpo Monastery at Shigatse, when he visits the city. Since the flight of the Dalai Lama to Mongolia in 1904, he has been recognized as the successor of that head of the Buddhist faith. Other great monastic establishments in the neighborhood are Dupon, 3 miles west, with 7500 monks and students; the Gandan, east of the city, with 2000 Lamas; and 1½ miles north, Sera, sheltering 5500 monks, taking its name from three large temples gilt all over within, *ser* being the Tibetan word for gold. The population scarcely exceeds 10,000 persons in civil life, of whom two-thirds are women, about 16,000 monks, and a small Chinese garrison. The affairs of the city, as of Tibet, are in the hands of the Dalai Lama, as the politico-religious chief, and two Chinese "Ambans" appointed every four years. Below these are native officials.

Among the few who succeeded in entering the forbidden city were Manning, in 1811; Huc and Gabet, in 1846; Nain Singh, an Indian surveyor, in 1874; Sarat Chandra Dass, in 1882; Narzunof and Zibikof, Russian subjects, and Kavagushi, the Japanese Buddhist, shortly before the British Mission of 1904 forced its way into the city. In 1906–07 a Chinese Mission visited Tibet, and Lhasa in particular.

Bibliography. Huc and Gabet, *Souvenirs d'un voyage en Tartary, le Thibet et la Chine* (Paris, 1852; Chicago, 1900); Sarat Chandra Dass, *A Journey to Lhasa* (Calcutta, 1885); W. W. Rockhill, "Tibet from Chinese Sources," in the *Journal of the Royal Asiatic Society* (London, 1891); L. A. Waddell, *Lhasa and its Mysteries* (ib., 1905); A. H. S. Landor, *Opening of Tibet* (ib., 1905); E. Candler, *The Unveiling of Lhasa* (ib., 1905); Millington, *To Lhasa at Last* (ib., 1905); T. H. Holdich, *Tibet the Mysterious* (New York, 1906); F. E. Younghusband, *India and Tibet* (London, 1910); Chuan, "The most Extraordinary City in the World," in *National Geographical Magazine*, October, 1912.

LHERMITTE, lĕr'mēt', LÉON AUGUSTIN (1844–). An eminent French painter and etcher. He was born July 31, 1844, at Mont Saint-Père (Aisne) and studied at Paris under Lecoq de Boisbaudran. He was of peasant parentage, and his great reputation rests upon his scenes of peasant life, rendered with great accuracy and power, in a large sculptural style and with little sentimental appeal. Particularly effective are the religious subjects in which he represents Christ surrounded by peasants in contemporary costume. He ranks as one of the most eminent painters of his day in France. His masterly draftsmanship and composition are particularly noticeable in his charcoal drawings, such as "Saying Grace." Fine examples of his paintings are "The Grandmother" (1881, Ghent Museum); "The Vintage" (1884, Metropolitan Museum, New York); "Harvester's Wages" (1882, Luxembourg); "The Friend of the Lowly" (1894, Boston Art Museum); "Death and the Woodcutter," one of the notable French pictures at St. Louis in 1904; "Among the Lowly" (1905, Metropolitan Museum, New York); "The Family" (1908, Corcoran Gallery, Washington); "Emigrants" (1909); "The Fishermen" (1909). He also painted mural decorations in the Sorbonne and the Hôtel de Ville, Paris, and landscapes of great power. As an etcher, he possesses great charm, purity, and spontaneity. He first essayed this medium in 1871 during a visit to England, where he collaborated in E. Lièvre's *Works of Art in the Collections of England* (1873) and in the *Portfolio*, an etching periodical. He also contributed plates to the *Gazette des Beaux Arts* and other French periodicals. Lhermitte was awarded a grand prize at the Paris Exposition of 1889 and in 1905 was elected a member of the Académie des Beaux-Arts and chosen professor in the Ecole des Beaux-Arts. Consult Henriet, *Les eaux-fortes de Léon Lhermitte* (Paris, 1905), and *International Studio*, vol. xxxviii (New York, 1909).

LHERZOLITE, lĕr'zō-līt (named from Lherz in the Pyrenees). An igneous rock of the peridotite (q.v.) family, of which the essential minerals are olivine, diallage, and an orthorhombic pyroxene.

LHÉVINNE, lā-vēn', JOSEF (1874–).

A celebrated Russian pianist. At eight he was playing in public, and at 15, after studying under Vassily Safonov (q.v.) at the Imperial Conservatory of Moscow, he won considerable distinction by a public performance, led by Rubinstein, of Beethoven's Fifth Concerto for piano and orchestra. In 1891 he received a gold medal from the Imperial Conservatory and four years later the Rubinstein prize at Berlin. He taught piano at the Imperial Conservatory in 1902–06. Thereafter he spent his time touring the world as a piano virtuoso. He visited the United States for the first time in 1906 and made several subsequent tours, always meeting with unqualified success.

L'HÔPITAL, lō'pē'tȧl', GUILLAUME-FRANÇOIS-ANTOINE DE, MARQUIS DE SAINTE-MESME and COMTE D'ENTREMONT (1661–1704). A French mathematician, born in Paris, the son of Gen. Anne-Alexandre de L'Hôpital. He early displayed remarkable mathematical ability, solving at the age of 15 certain problems on the cycloid proposed by Pascal. For a short time he studied with Johann Bernoulli, when the latter was in Paris. He entered the army and served for some time as captain of cavalry, but his extreme myopia compelled him to relinquish his chosen profession. The rest of his life was devoted to mathematics. He was one of the first to put into intelligible language the Leibnitzian theory of the calculus. In 1693 he was made honorary member of the Academy of Sciences of Paris and soon thereafter added to his reputation by a number of important discoveries in the new analysis. He found the curve whose tangents, terminated by the axis, are proportional to the segments of the axis intercepted between the curve and the tangent, and solved the problem of the brachistochrone. His first great work, and the first treatise to popularize the new calculus, was the *Analyse des infiniment petits pour l'intelligence des lignes courbes* (1696, and numerous subsequent editions). He died of apoplexy before the publication of his second work, *Traité analytique des sections coniques* (1707; Eng. ed., 1723). His numerous memoirs on mathematical subjects are to be found in the *Recueil de l'Académie des Sciences* (1699–1701) and in the *Acta Eruditorum* (1693–99).

L'HÔPITAL, MICHEL DE (1507–73). A French statesman, born near Aigueperse in Auvergne. He was the son of the Constable de Bourbon's physician. Implicated in the disgrace of the Constable, young L'Hôpital was imprisoned for a time in 1523, but eventually escaped to Italy, where at Padua and Bologna he completed after six years the law studies begun at Toulouse and accepted a civil office at the papal court in Rome. On returning to France, in 1534, he soon became a counselor in the Parliament of Paris (1537) and was employed on various diplomatic missions, and through successive offices he gradually rose to be Chancellor of France in 1560. It was with the aid of Catharine de' Medici, and in opposition to the Guises, that he was thus elevated, and the policy he inaugurated was one of tolerance and conciliation towards the Huguenots. The Prince of Condé was pardoned; meetings of the Notables and of the States-General were held; and the important Ordinance of Orléans (1561) marked a step forward in the development of the state in that it abolished the Concordat of Francis I, did away with many feudal abuses, and reformed the judiciary. On the accession of Charles IX, in 1560, L'Hôpital obtained pardon for many of the condemned Huguenots, and in September, 1561, arranged the famous conference at Poissy between leading Catholic and Protestant theologians for the purpose of effecting a reconciliation between the two parties. The contending factions, however, failed to come to any agreement, and the failure of the conference only widened the breach and made recourse to arms inevitable. During the civil war that followed L'Hôpital continued his administrative reforms, and in 1566 put forth the Ordinance of Moulins, which was designed to protect the royal domains and to reform the magistracy and courts of France. Two years later the great Chancellor was forced from active office by the change in the policy of Catharine de' Medici and the hatred of the Guises and the Ultramontanes. He quitted the court in May, 1568, but it was not until Feb. 1, 1573, that he was compelled to resign the chancellorship. His honors and property were guaranteed to him for the rest of his life. He died March 13, 1573. He was an author of some note and wrote Latin verses. His works, which were published under the title *Œuvres complètes de Michel de L'Hôpital* (5 vols., Paris, 1824), edited by Dupuy de l'Yonne, contain much that is of interest for the history of France in the sixteenth century. Consult: Villemain, *Vie de L'Hôpital* (Paris, 1874); Dupré-Lasale, *Michel de L'Hôpital* (ib., 1875); Scitte, *Un apôtre de la tolérance au XVIème siècle: Michel de L'Hôpital* (Montauban, 1891); Fournier de Flaix, *L'Hôpital, son temps et sa politique* (Paris, 1900); Shaw, *Michel de L'Hospital and his Policy* (Oxford, 1905).

LHUYS, EDOUARD DROUYN DE. See DROUYN DE LHUYS, EDOUARD.

LI, lē. The name of a variable Chinese measure of length. In theory the li exists as measuring 1800 land feet (which vary in different parts of China from 8.6 to 27.8 inches). Based on the "chih," the foot of 14.1 English inches of the treaty regulations, the li equals 705 yards, or four-tenths of a statute mile. According to H. B. Morse, *The Trade and Administration of China* (p. 175, rev. ed., London, 1913), the li "is one-hundredth of the distance a laden porter will cover in a day of ten hours' marching; on the plain this would represent a third of a mile, . . . but in hilly country it varies considerably."

LIABILITY. In the broadest sense, any obligation enforceable at law or in equity, including legal obligations to perform acts other than the payment of money. The term is generally used, however, in a narrower sense as meaning a legal obligation to pay money: either a sum certain due and owing, as in the case of a debt, or an unliquidated sum, as in case of damages due upon tort or upon breach of contract. The source of all legal liability is either contract (q.v.), quasi contract (q.v.), or tort (q.v.). As a legal term, the word is not properly applicable to responsibility under the criminal law. Consult Parsons, *Law of Contracts,* and Pollock, *Law of Torts.* See CONTRACT; DEBT; EMPLOYER'S LIABILITY; JOINT LIABILITY; LIMITED LIABILITY; QUASI CONTRACT; TORT; LABOR LEGISLATION.

LIABILITY, JOINT. See JOINT LIABILITY.

LIADOV, lyȧ'dôf, ANATOLE (1855–1914). A Russian composer and conductor, born at St. Petersburg. He received his first musical education from his father, an orchestral conductor, and then entered the St. Petersburg Conservatory, where Rimski-Korsakov (q.v.) was his teacher in composition. He graduated in 1877, and the following year was appointed teacher of theory, later becoming professor. In 1894 he accepted the conductorship of the St. Petersburg Musical Society. His most important compositions are his works for pianoforte, mostly in the smaller forms and strongly influenced by Chopin and Schumann, yet with sufficient admixture of distinctive Russian characteristics to save him from the charge of being a mere imitator. He also wrote a scherzo, a mazurka, and a polonaise for orchestra, and some choral works with orchestra.

LIAKHOV, lyȧ′ᴋôf. A group of islands in the Arctic Ocean. See New Siberia.

LIANAS, lĭ-ā′na*z* (Fr. *liane*, creeper, from *lier*, to bind, from Lat. *ligare*, to bind). Plants which climb either by twining or by means of tendrils or other structures. While climbing plants are found in all parts of the world to a greater or less degree, their peculiar home is in the rich tropical forests. There they form dense jungles among the trees, in some cases making passage almost impossible. The various methods by which plants climb may be briefly mentioned. Some forms twine about the stem of the host plant, as the morning-glory and the bittersweet; others climb by means of tendrils, as the grape and the pea; still others by means of rootlets, as various ivies. Some plants which have one or more of these means for climbing also have thorns which in a measure help to secure attachment to the branches of the host; various greenbriers well illustrate this. Their advantage is clear, inasmuch as they are able to grow up to the light in a comparatively short time and at a comparatively slight cost. Lianas often show structures which seem to adapt them well to their life conditions. Among these perhaps the most conspicuous are the mechanical tissues and the conducting tissues.

LIANCOURT, F. A. F. See La Rochefoucauld-Liancourt.

LIAOTUNG, lē̇-ou′tụng′ (Chin., river east). A name originally applied to that portion of south Manchuria which lies to the east of the river Liao—that on which the port of Newchwang is situated, the portion to the west being known as Liaosi. The name now includes both and is nearly synonymous with Shingking. The term has sometimes been restricted, wrongly, to the peninsula on which Port Arthur is situated, sometimes called the Regent's Sword.

LIAO-YANG, lē̇-ou′yäng′, Battle of. See Russo-Japanese War of 1904–05.

LIAPUNOV, lyä′pụ-nôf, Sergei Mikhailovitch (1859–). A Russian composer, born at Yaroslav. He studied music at Nizhni Novgorod and at the Moscow Conservatory. After his graduation in 1883 he lived in St. Petersburg, engaged in teaching and composing. In 1893 he was ordered by the Imperial Geographical Society to collect the folk songs of several Russian provinces, and these he later helped Balakirev and Liadov (qq.v.) to harmonize. From 1894 to 1902 he was assistant director of the court chapel. Among his more important compositions are a ballad, a polonaise, a festival overture, a symphony in B minor, and a concerto for piano and orchestra. His other works include preludes, mazurkas, valses, 12 *études d'exécution transcendante* for piano, and 35 Russian national songs with piano accompaniment.

LIAR, The. A farce by Foote, founded on Corneille's *Le menteur*. It was produced in 1761.

LIARD, lyȧr, Louis (1846–). A French philosopher and educator, born at Falaise (Calvados). He taught in several lycées, was director of higher education in the Ministry of Public Instruction (1884–1902), and in 1902 was appointed vice rector of the Academy of Paris. By the furtherance of exchange lectureships he helped to strengthen the ties of scholarship between France and the United States. He became a Grand Officer of the Legion of Honor and a member of the Institute. His works include: *Des définitions géométriques et des définitions empiriques* (1873–88); *Platon, le septième livre de la République* (1875); *Cicéron: des vrais biens et des vrais maux* (1875); *Descartes: Discours de la méthode* (1877); *Les logiciens anglais contemporains* (1878–90); *La métaphysique et la science positive* (1879–1905); *Morale et enseignement civique* (1881–1905); *Descartes* (1882–1903); *Universités et facultés* (1890); *L'Enseignement supérieur en France; Notice sur la vie et les travaux de Jules Simon* (1898); *Pages éparses* (1902). After 1902 his writing, mainly on educational lines, included *Nouveau plan d'études de l'enseignement secondaire, les cadres, l'esprit* (1903); *L'Université de Paris* (2 vols., 1910).

LIAS′SIC SERIES (Fr. *lias*, OF. *liais*, *liois*, from Bret. *liach*, *leach*, Welsh *llech*, Gael., Ir. *leac*, stone). The lower division of the Jurassic system. The formation is of special importance in western Europe; in the United States Liassic rocks occur only in California and Oregon. In England the rocks comprise clays, sands, and limestones, aggregating more than 1000 feet in thickness and divisible into three stages: Lower, Middle, and Upper Lias. Fossil remains are abundant and include among the higher forms Ichthyosaurus, Plesiosaurus, Dimorphodon (qq.v.), and other reptiles. See Jurassic System.

LIBA′NIUS (Lat., from Gk. Λιβάνιος) (314–393 A.D.). One of the latest and most eminent of the Greek sophists or rhetoricians. He was born at Antioch in Syria, studied at Athens under various teachers, and first set up a school in Constantinople, where his lectures were so attractive that he emptied the benches of the other teachers of rhetoric, who had him brought before the prefect of the city on a charge of "magic" and expelled. He then proceeded to Nicomedia, but after a residence of five years was forced by intrigues to leave it and returned to Constantinople. Here, however, his adversaries were in the ascendant; hence, broken in health and spirit, he settled down in his native city of Antioch in 354, where, after a long career as a teacher, he died. Libanius was the instructor of St. Chrysostom and St. Basil, who always remained his friends, though Libanius was himself a pagan, and of Ammianus Marcellinus (q.v.). He was a warm friend of the Emperor Julian (q.v.), who corresponded with him. His works are numerous and mostly extant, consisting of orations, declamations, narratives, 1607 letters, etc. The most complete edition of the orations and declamations is that by Reiske (4 vols., Altenburg, 1784–97), and, of the letters, that by Wolf (Amsterdam, 1738). Since 1903 a new complete edition, by Förster, has been under way. No complete English translation of the works of Libanius exists, but 16 of his letters to Julian have been translated by Duncombe, *The Works of the Emperor Julian*, vol. i, pp. 303–332 (3d ed., London, 1798); the monodies *On Nicomedia* and *On the Temple of Apollo at Daphne* are published by the same author (vol. ii, pp. 227–251). Libanius' *Funeral Oration on the Emperor Julian* is translated by King, *Julian, the Emperor* (London, 1888). Consult: Petit, *Essai sur la vie et la correspondance du sophiste Libanius* (Paris, 1866); Sievers, *Das Leben des Libanius* (Berlin, 1868); J. E. Sandys, *A History of Classical Scholarship*, vol. i (2d ed., New York, 1908); J. W. H. Walden, *The Universities of Ancient Greece* (ib., 1909).

LIB′ANUS, MOUNT. See LEBANON, MOUNT.

LIBA′TION (Lat. *libatio*, from *libare*, to take a portion of, Gk. *λείβειν*, *leibein*, to pour out; the commoner Latin noun, however, is *libamentum*). Anything poured out for the gods, as an act of homage or worship; a drink offering. Such a libation was usual among the ancient Romans as a part of the sacrifice at an altar, and at home, at the beginning of meals or banquets, in homage to the *lares* (q.v.), or household gods. The term "libation" has often also a wider significance, including not only the wine poured upon the altar, but often the little sacrificial cake, *libum*, that was placed there.

LIBAU, lē′bou (Russ. *Labava*). A fortified seaport in the Province of Courland, Russia, on the Baltic. It is situated on the end of a sandy tongue of land which separates Lake Libau from the sea, through which runs the channel, dry in 1703, which divides the city into two parts (Map: Russia, B 3). Libau is well built and consists of the old and new town; in the latter, on the right bank of the channel, are the large factories, the grain elevators, mills, etc. Libau has two Gymnasia, a high school for women, a naval school, a public library, and a number of other educational institutions. It has also a large public garden. The industries, formerly unimportant, have greatly increased, the principal articles of manufacture being farm machinery, flour, timber, sails, explosives, matches, colors, soap, beer, ropes, and furniture. There is an extensive export trade in eggs, flour, flax, spirits, petroleum, horses, flax, timber, pork, and notably grain; while the chief imports are coal and herrings. Libau is connected directly by rail with the wheat regions of the Empire. At the entrance to the channel, 2 miles from the centre of the town, is the commercial or winter harbor, an artificial harbor constructed between 1893 and 1904, which is ice-free throughout the year. To the north of the town is the naval harbor of Alexander III, very strongly fortified and protected by moles and breakwaters, near which is the Orthodox Naval Cathedral, which was consecrated in 1903. Pop., 1897, 64,500; 1913, 90,400, 20 per cent being Jewish. Libau is a popular bathing resort. As a seaport, it is first mentioned in 1263 under the name of Portas Liva. It was fortified by the Livonian Knights in 1301 and passed to the possession of Russia in 1795. During the European War which broke out in 1914, Libau was several times shelled by German warships. Each time the city was set on fire and considerable shipping destroyed. See WAR IN EUROPE.

LIB′BEY, WILLIAM (1855–). An American scientist, born in Jersey City, N. J. In 1877 he graduated at Princeton, where he was assistant professor of physical geography (1882) and of histology (1883–98) and professor and director of the Museum of Geology and Archæology after 1883. He also became fellow of the Geographical and Geological societies of London and Paris and vice president of the American Society of Naturalists. He led scientific parties to Hawaii, Mexico, and Cuba, and visited Greenland in the summer of 1894 and again in the summer of 1899. He published *The Jordan Valley and Petra* (1905).

LIBBY, CHARLES FREEMAN (1844–1915). An American lawyer. He was born at Limerick, Me., graduated from Bowdoin College in 1864, and studied at Columbia Law School in 1865–66. Admitted to the bar in 1866, he practiced at Portland, Me., after 1868; was a Republican member of the Maine Senate in 1889–92 and its president in 1891–92, and became president of the Portland Railroad Company in 1904. He was president of the Maine State Bar Association in 1891–96, of the Cumberland Bar Association in 1907, and of the American Bar Association in 1909–10. From 1891 to 1912 he served as president of the overseers of Bowdoin.

LIBBY PRISON. A Confederate military prison during the Civil War, situated in Richmond, Va. It was a building three stories high in front and four in the rear, containing six rooms (excluding the cellar), each about 105 by 45 feet. Before the Civil War it was used by its owner, a Mr. Libby, as a tobacco warehouse. It was first used as a prison after the first battle of Bull Run and continued to be thus used until the close of the war. At times as many as 1200 prisoners were confined there, most of them being Federal officers. The Confederate officers in immediate charge were Major Thomas P. Turner, commander, and Richard Turner, inspector. The prisoners suffered terribly from starvation, cold, and other causes, and many died or had their health permanently shattered while in confinement. At Libby there were bathrooms, but no soap. The ventilation was good. Many attempts at escape were made, the most famous being that of Feb. 9, 1864, when 109 prisoners made their exit through a tunnel 50 feet in length, which had been laboriously excavated by a small party of men under Col. Thomas E. Rose. Of the 109, 48 were recaptured, 2 were accidentally drowned, and 59 reached the Federal lines. In 1888–89 the building was taken apart, carried to Chicago, and there reconstructed. In September, 1889, many valuable relics having been stored in it, it was formally opened as the Libby Prison War Museum.

LIBEL (OF. *libel*, *libelle*, *libeau*, Fr. *libelle*, from Lat. *libellus*, dim. of *liber*, book, inner bark of a tree). In admiralty practice, the first pleading of the complainant, which is filed in the office of the clerk of the court to commence the action. It is in the form of a petition addressed to the judge of the court by name, setting forth the nature and facts of the claim and containing a prayer that process issue in the proper manner. If the action is against an individual, a citation (q.v.) will issue directing him to appear and answer; if against a vessel or cargo, a writ issues to an officer of the court directing him to attach it, which is considered sufficient notice to the owners. The libel must be verified by the libellant, as the claimant is called, or his agent if the libellant is without the jurisdiction.

The term was borrowed from the Roman law, where a pleading known as the *libellus conventionis* was employed in certain forms of action. Thus, in course of time, the term "libel" came to designate the first pleading in an action under the civil law. It corresponds to the complaint or declaration at common law and to the petition or bill in a chancery suit. See ADMIRALTY LAW; PLEADING.

LI'BEL. A term of the common law, descriptive of that species of defamation which is committed by writing or its equivalent. It consists of the publication of that which tends to bring another into hatred, contempt, or ridicule, and is a criminal offense as well as a civil wrong. Special damage to its victim need not be shown. Nor is the truth of a libelous publication always a defense. Many of our State constitutions declare that it is not a defense to a criminal prosecution, unless published with good motives and for justifiable ends. Fair reports of legislative debates, judicial proceedings, and similar transactions, however injurious in fact, do not subject their publishers to action for libel. Various other immunities are accorded to news gatherers and publishers by modern statues.

A defamatory writing will not subject its author to an action, either civil or criminal, until it is published. For the purposes of a criminal prosecution, it is published as soon as any one knowingly exposes it to the sight of another, who is capable of understanding it. Accordingly the writer of a defamatory article may be liable criminally if he sends it in a sealed envelope to the one defamed. To render him liable in a civil action for damages, however, the writing must have been communicated to a third person; save in a few States, where the rule has been changed by statute. Such communication need not have been intentional. One who sends the writing to a third person by mistake may inflict as great an injury upon the victim of his defamation as though he had planned the injury. Nor can the publisher of a libel screen himself from civil responsibility by saying that it was a joke. In the language of a great judge, "no one can cast about firebrands and death, and then escape from being responsible by saying he was in sport."

A century and a half ago the weight of judicial authority favored the rule that the defamatory character of a publication was a question of interpretation and therefore one for the court and not for the jury to determine. Lord Mansfield's inflexible enforcement of this rule elicited much criticism and led to the enactment of a statute known as Fox's Libel Act (32 Geo. III, c. 60). This statute has generally been reenacted in the United States. Although in terms it only applies to criminal proceedings, it has been followed by analogy in civil actions for libel, and no plaintiff is entitled to succeed, either in England or in the United States, unless the jury find that the publication is libelous. In a civil action, if the judge is of the opinion that the publication complained of is not defamatory, he may, however, direct that the plaintiff be nonsuited.

LIBELT, lē'bĕlt, KAROL (1808–75). A Polish politician and author, born in Posen. He studied philosophy and mathematics in Berlin, entered the Polish Revolutionary army in 1831, and was imprisoned for nine months at Magdeburg. From 1840 to 1845 he edited at Posen two Polish newspapers, in 1845 was a member of the Revolutionary Central Committee, and in the next year was elected a member of the Provisional Government at Cracow. He was sentenced to 20 years' imprisonment for his part in this uprising, but regained his freedom after the revolution of March, 1848. He was a member of the Prague Slavic Congress, of the Frankfort Parliament of 1848, and in 1873 was elected to the Prussian Lower House. His writings include: *Filozofia i krytyka* (1845–50), Hegelian in tendency; *Estetyka* (1851); *Umnictevo* (1857), a system of ethics; *Dziela* (1875); *Zbior pism pomniejszych* (1849–51), political papers; *Dziewica Orléanska* (1847); and the sketches *Humor i pravada* (1852).

LI'BER (Lat. *Līber*). The name of a Roman deity, identified by the Romans with Bacchus. Consult W. W. Fowler, *Roman Festivals*, 54–56 (London, 1899), and Georg Wissowa, *Religion und Kultus der Römer* (2d ed., Munich, 1912).

LIBER (Lat. *lĭber*). The ancient Latin name for a book. See BOOK; CODEX; LIBRARIES; PAPYRUS; PARCHMENT.

LI'BERA. In Roman mythology, the wife of Liber (q.v.), worshiped with him in conjunction with Ceres, and identified with Persephone. Her festival, Liberalia, occurred on the 17th of March. Consult W. W. Fowler, *Roman Festivals* (London, 1899), and Georg Wissowa, *Religion und Kultus der Römer* (2d ed., Munich, 1912).

LIBERAL ARTS. See ARTS, LIBERAL.

LIBERA'LIA. See LIBERA.

LIBERAL'ITAS JU'LIA. See EVORA.

LIBERAL REPUBLICAN PARTY. In American history, the name given to a short-lived political party which participated in the presidential campaign of 1872, composed largely of "bolters" from the regular Republican organization. The party first appeared as a prominent political factor in Missouri in 1870, under the leadership of Carl Schurz and B. Gratz Brown, the latter of whom, by a fusion of Liberal Republicans with a large element of the Democratic party, was elected Governor. The faction here declared for "universal amnesty and universal enfranchisement," a reform in the tariff, an effective civil-service system, and a cessation of "unconstitutional laws to cure kuklux disorders, irreligion, or intemperance." As President Grant's first term drew near its close, disaffection in the Republican ranks throughout the country became increasingly pronounced, chiefly because of the President's policy of severity with regard to the Southern whites and his alleged misuse of his appointing power. In answer to a call issued by the triumphant fusionists of Missouri on Jan. 24, 1872, a National Liberal Republican Convention met at Cincinnati on May 1, and after much discussion Horace Greeley was nominated for President and B. Gratz Brown for Vice President, on a platform which, evading the tariff issue, declared for universal amnesty, the reëstablishment of civil governments throughout the South, and civil-service reform. On June 9 the Democratic Convention assembled at Baltimore formally accepted the candidates and the platform of the Liberal Republicans, though a dissenting element subsequently met at Louisville and nominated Charles O'Conor for President and John Quincy Adams for Vice President. The campaign was marked by much ill feeling and considerable personal abuse, Greeley being especially attacked because of his affiliation with the Democrats, whom formerly, as a Republican, he had consistently opposed. In the election the fusion candidates were overwhelmingly defeated, Grant, the Republican candidate, being reëlected by an electoral vote of 286 to 63. The party did not survive. Among others who had been more or less prominently identified with the party were Charles Francis Adams, Lyman Trumbull, Carl Schurz, David Davis, Stanley Matthews, Horace White, George W. Julian, and David A. Wells. Consult: J. A. Woodburn, *Political Parties in the United States* (New York, 1903); S. D. Fess, *History of Political Theory and Party Organization in the United States* (Boston, 1910); McLaughlin and Hart (eds.), *Cyclopedia of American Government*, vol. ii (New York, 1914).

LIBERAL UNIONISTS. A political party formed in Great Britain in 1886 through a division in the Liberal party. It was headed by Lord Hartington, Joseph Chamberlain, and G. O. Trevelyan, and was composed of those Liberals who thought that the Empire should be preserved "compact and complete." The division then took place upon the introduction of the Home Rule Bill by Mr. Gladstone. For a number of years after their secession the Liberal Unionists maintained their separate organization and claimed to stand for distinctive principles. But they have since, for all practical purposes, become merged in the Conservative party. Consult West Ridgeway, "The Liberal Unionist Party," in the *Nineteenth Century* (London, August and October, 1905).

LIB'ERATOR, The (Sp. *El Libertador*). A name applied to the South American patriot Bolívar.

LIBERATOR, The. An antislavery journal founded in 1831 by William Lloyd Garrison. It was published until 1865.

LIBERATORE, lē-bȧ'rȧ-tō'rȧ, Niccolò di. See Niccolò da Foligno.

LI'BER DIUR'NUS RO'MANO'RUM PONTIF'ICUM (Lat., Journal of the Roman Pontiffs). The title of a collection of formulas used in the papal chancery from the fifth to the eleventh century in preparing certain documents, e.g., when sending the pallium, granting special privileges, papal appointments, etc. Owing to altered conditions, it was no longer useful and so was laid aside and after a time forgotten. When manuscript copies were discovered in Rome and elsewhere in the seventeenth century, preparations were made for printing it, but the censorship refused permission; and though it was printed in Paris by the Jesuit Garnier (1680), the first official edition came out under the auspices of Benedict XIII in 1724. The best edition of the Vatican manuscript is that of T. E. von Sickel (Vienna, 1889). The Milan manuscript, discovered after the printing of Von Sickel's edition, was edited by Ratti (Milan, 1891).

LIBE'RIA (Neo-Lat., from Lat. *liber*, free). A negro republic of West Africa, lying on the Atlantic shore between Sierra Leone on the west and the Ivory Coast on the east (Map: Africa, D 4). The coast line is about 350 miles long, extending from the Mano to the Cavally. The area is estimated at 40,000 square miles. The boundaries were not fixed with England and France until 1885 and 1892, that part of the interior which drains into the Niger having finally, in the latter year, fallen to France. Only the coast strip, with an average width of 7 miles, is developed and administered. It is swampy and flat. The interior is elevated and clothed with valuable forests of gum trees, oil palms, and pepper shrubs. The hill land is healthful and naturally productive and is the abode of elephants and buffaloes. Among the numerous rivers—all comparatively small—are St. Paul's (supposed to be 200 miles long and navigable for 25 miles), St. John's, and Cestos. Many metals have been found, and the republic is supposed to be rich in them, but as yet they have not been found in payable quantities. The climate has been called the hottest known on the globe, but is not considered so dangerous to white men as that of Sierra Leone. January is the warmest month. There are two rainy seasons, yielding over 150 inches of rain per year—one in June and July, the other in October and November.

The soil along the coast is very rich, but in general cultivation is neglected. The staple product is coffee. Mining and industrial development has scarcely begun. There are several American, English, and German factories, or trading stations. Foreign commerce is not in a flourishing condition. In 1910 imports were valued at $1,667,857 and exports at $1,199,152. The chief exports are palm oil, piassava, palm kernels, rubber, and ivory. About 70 per cent of the trade was with Germany.

The constitution is framed after that of the United States. The executive authority is vested in a President and Vice President (elected for four years) and a council of six members. The legislative power rests with a Congress of two houses—the Senate (8 members) and the House of Representatives (14 members). Voters must be of negro blood and own real estate. The natives generally do not avail themselves of the suffrage. No foreigner can own land without the consent of the government. The coast territory is formed into the counties of Bassa, Maryland, and Sino, with one superintendent each, and Montserrado, with four superintendents. The capital is Monrovia (named after President Monroe of the United States). The estimated revenue for 1914 was $531,500. Revenue and expenditure in 1902 were $310,000 and $318,110 respectively; in 1911–12, $471,335 and $470,000. The revenue is derived mainly from customs duties. A debt of £100,000 was contracted in 1871; the unpaid interest in 1910 amounted to £185,000. The internal debt on Jan. 1, 1914, was $200,000; the total public debt (including those just mentioned and others) on that date was $1,352,000. In 1911 a plan was agreed upon, with the approval of the United States, Great Britain, France, and Germany, whereby Liberian finance should be administered by an American controller and British, French, and German subcontrollers. The plan involved the raising of an international loan of £500,000, secured by the customs, head tax, and rubber tax. It was also provided that the Liberian army be reorganized by American officers to assure the maintenance of peace. British money is used, but American money figures usually in the keeping of accounts. There is a Liberian coinage and a rather large paper currency. The weights and measures are, as a rule, British. The official language is English.

Defense. All able-bodied men between the ages of 16 and 50 are liable for military service. The active military forces consist of militia, volunteers, and police, the total force being estimated at about 400 men. Under an agreement between the United States, France, Germany, and Great Britain (1911), the United States designated an officer of its army to organize a frontier police to maintain peace and provide for the security of the revenues.

The population is estimated to be about 2,000,000, some, however, putting it much lower. There are supposed to be from 12,000 to 15,000 Americo-Liberians. Besides these there are in the coast region some 40,000 civilized and christianized natives, mostly Episcopalians. The indigenes are chiefly as follows (with allied tribes): Mandingo (Mohammedan), Kisi, Vai, Kpwesi, Gora, and Kru. In 1910 there were 113 public primary schools, with 4100 pupils. There are reported 87 mission schools, with about 3000 pupils. A few institutions exist for more advanced education, including a government college, with about 120 students. The experiment of negro self-government in Liberia cannot yet be pronounced a success.

History. The State of Liberia owes its origin to the efforts of the National Colonization Society of America (see COLONIZATION SOCIETY), organized in 1816 to colonize in Africa the free people of color in the United States. The first attempt to locate, which was made in Sherbro Island south of Sierra Leone (1820), because of the excellent harbor there, failed because of the unhealthfulness of the locality; but in December, 1821, a treaty was concluded by Lieutenant Stockton with certain native princes, by which a tract of land fit for the purpose was acquired about Cape Mesurado. It was some weeks before the hostility of the natives, who were wedded to the slave trade, could be overcome, but in April, 1822, active operations were begun on the mainland. A 30-acre tract was allotted to each man, with the means of cultivating it. The society's agents became discouraged at the difficulties that were met and returned to America with a few faint-hearted ones; but the others rallied about a determined negro, Elijah Johnson, and remained. The colony was enlarged by the purchase of new tracts. New settlements were afterward formed at Cape Monte and in the newly acquired Bassa Land, in which, in 1834, a town was founded, and called Edina, in acknowledgment of pecuniary aid sent to the colony from Edinburgh. Many of the neighboring chiefs were received into the colony, and others were subdued. Trials of many kinds, deprivations, and dissensions, were the lot of the colony, managed by a society which did not fully know whether its aims were sentimental or practical. In 1847 Liberia was left to its own resources and declared an independent republic and recognized as such by most of the important countries in the world. The colony began to show more prosperity; numerous churches and schools were founded, a regular postal system was introduced, newspapers were established, and slavery in the neighboring states was abolished. Conventions in 1885, 1892, and 1903 with Great Britain and France defined minutely the boundary between Liberia and their colonial possessions. In 1909 President Roosevelt appointed a commission to investigate the general status of affairs in Liberia. As a result, it was announced in the following year that the United States, acting in harmony with Great Britain, France, and Germany, would hereafter supervise military, financial, boundary, and agricultural questions in the negro Republic. A $2,000,000 loan was floated by an Act of the Legislature in 1911. Mr. Daniel Howard was elected President in 1912. He immediately got into difficulty with Germany because of insults offered to merchants. Two German gunboats forced an apology. Liberia retaliated by granting privileges to English traders in 1913.

H. Johnston, *Liberia, with an Appendix on the Flora of Liberia by Otto Stapf* (2 vols., New York, 1906), which is the best book yet written on the country; and Wallis, "A Journey through the Liberian Hinterland," in the *Geographical Journal* (1910).

LIBE'RIUS. Pope, 352–66. He was born in Rome, but nothing is known of his history prior to his pontificate, which fell in the stormiest period of the semi-Arian controversy. (See ARIUS.) The Emperor Constantius supported the semi-Arian party with all his authority; and the Council of Aries in 353, and that of Milan in 355, formally condemned Athanasius (q.v.), the great representative of the orthodox belief. Liberius refused to confirm this decree. He was in consequence deposed and banished to Berœa by the Emperor, who caused a Roman deacon, Felix, to be elected in his stead. He was restored to his see in 358, but the terms on which he was recalled are much disputed. He survived his return from exile eight years and died in high repute for sanctity at Rome, Sept. 24, 366. In the traditions of the sixth or seventh century the relations between Liberius and Felix were completely reversed, and Liberius was made out to be an antipope, a heretic, and a tyrant. The only remains of Liberius are some letters preserved by Constant in the *Epistolæ Romanorum Pontificum* (Paris, 1821), reprinted in Migne, *Patrol. Lat.*, viii, German translation in *Bibliothek der Kirchenväter* (Kempten, 1876). In the Greek church Liberius is commemorated on August 27; in the Latin, on September 23. Consult Döllinger, *Pabstfabeln* (Munich, 1890).

LI'BER PON'TIFICA'LIS (Lat., pontifical book). A history of the bishops of Rome beginning with the Apostle Peter and extending to

Nicholas I (867), with an addition subsequently made of the times of Adrian II and Stephen VI (891). Anastasius, librarian of the Church under Nicholas I and abbot of a convent in Rome, was formerly supposed by many to be the author of the book; but later investigations have shown almost certainly that it existed before his time. The oldest materials now known that were used in the compilation of it were furnished by a list of the popes down to Liberius, which was probably written before his death (366). The original manuscript has been lost, but several copies of it, taken in the seventeenth century from other copies, are extant. Another list of the popes comes down to Felix IV (530). Parts of it are almost literal copies from the former, but many additional particulars are given, drawn from various sources and having different degrees of historical value. Both lists were afterward continued and ultimately formed the Liber Pontificalis, the oldest-known copy of which belongs to the end of the seventh or the beginning of the eighth century. A first continuation of it extends to Gregory II, who became Pope in 714, and a second ends with Stephen III (757). After this time several other continuations were made, the latest of which terminates, as has been mentioned, with Stephen VI (891). Besides the sources already spoken of, materials for the history were furnished by traditions, written documents, buildings, inscriptions, and other monuments. Additions to the book have been made: 1. By three histories of the popes, the authors of which are not known, (*a*) from Lando (913) to Gregory VII (1073) and belonging to the eleventh century; (*b*) extending down to the same date and written during Gregory's life; (*c*) from Paschal II, in the early part of the twelfth century. 2. By a history written in the thirteenth century, extending from Gregory VII to Honorius II (1129). 3. By histories originating at the close of the twelfth century. The text is published in Migne, *Patrol. Lat.*, cxxvii, cxxviii (under Anastasius), but much better by L. Duchesne (2 vols., Paris, 1884–92), and by Mommsen in *Monumenta Germaniæ Historica* (Berlin, 1898 et seq.).

LIBER STU′DIO′RUM (Lat., book of studies). A set of prints from engraved plates prepared by J. M. W. Turner from his own designs and published in parts between the years 1807–16. The intention was, probably, to issue 100 plates, but only 71 were published, of which number one, the frontispiece, did not appear until several years after the commencement of the work and was then presented to the subscribers. More plates had been prepared, and prints from some of these are accessible. They are called "the unpublished plates" and are of very great value. The first scheme seems to have been to use aquatint (q.v.) for the plates, with a skeleton or substratum of etched outline by Turner's own hand. The great majority of the plates are, however, in mezzotint, done by Charles Turner, T. Hodgetts, G. Clint, Thomas Lupton, and others; and the etching of each plate was in nearly every case by the designer himself, J. M. W. Turner. These etchings are generally of the most extraordinary merit and interest, and copies of them are greatly in demand. A very few of the plates are entirely in mezzotint, and by Turner himself, and these are of especial and peculiar importance to the student of landscape art. Single prints in the first state are quoted at several hundred dollars. A complete set in the finest condition may be worth $10,000. The biographies of Turner treat of *Liber Studiorum*, as it forms an important episode in the early prime of the artist's life.

Bibliography. Good special commentaries are: Pye, *Notes and Memoranda Respecting the Liber Studiorum of Turner* (London, 1879); Brooke, *Notes on the Liber Studiorum of J. M. W. Turner* (ib., 1885); W. G. Rawlinson, *Turner's Liber Studiorum: A Description and Catalogue* (2d ed., London, 1907); *Liber Studiorum*, with introduction by C. F. Bell (New York, 1911); also the interesting discussion in W. Armstrong, *Life of Turner* (London, 1902).

LIBERTAD, lē ʙâr-täᴅ′. A maritime department of Peru, bounded by the departments of Lambayeque, Cajamarca, and Amazonas on the north, Loreto on the east, Ancachs on the south, and the Pacific Ocean on the west (Map: Colombia, B 5). Its area is estimated at over 10,200 square miles. A large part of the surface is occupied by the Andes. The strip along the coast is dry and low. The eastern part is crossed from south to north by the upper course of the Marañon (Amazon). Some of the valleys in that part of the department are very fertile. Agriculture and stock raising are carried on to some extent. Mineral deposits are supposed to exist in the mountains, but mining is neglected. Pop. (est.), 250,000. The capital is Trujillo (q.v.).

LIB′ERTIES, The. The name given to a district of Dublin, Ireland, formerly the home of citizens holding certain privileges. It contained many magnificent residences, but is now occupied by the poorer classes.

LIB′ERTINES (Lat. *libertinus*, relating to a freedman, from *libertus*, freedman, from *liber*, free), Synagogue of the. A synagogue at Jerusalem, mentioned in Acts vi. 9: "Then there arose certain of the synagogue, which is called the synagogue of the Libertines, and Cyrenians, and Alexandrians, and of them of Cilicia and of Asia, disputing with Stephen." The expression is taken by most scholars to mean a synagogue of freedmen, referring to Jews who had been taken captive by Pompey, carried to Rome, and afterward set free, and whose descendants may have returned to Jerusalem and formed, either alone or with other Jews, a synagogue there. A geographical term, however, would suit the context better in view of the four other geographical names. And in view of the African names Alexandria and Cyrene, it would seem that an African name should head the list. The reading *Libystines* has been suggested as the original reading, which was easily corrupted into *Libertines*. This suggestion finds some support in an Armenian version which reads "of Libyans." If this plausible suggestion be accepted, the passage refers probably to two synagogues—one made up of African Jews from Libya, Cyrene, and Alexandria; the other made up of Jews from Cilicia and Asia. Consult Friedrich Blass, *Philology of the Gospels* (New York, 1898).

LIBERTINES, The, or Spiritualists. 1. An odious and pernicious sect that sprang up in the sixteenth century in the Reformed church of France. They arose in Flanders about 1525, perhaps as a recrudescence of the ancient Beghards (see Beguines) and Brothers and Sisters of the Free Spirit (q.v.). They are said to have made 4000 proselytes in France alone, and not only among the lower classes but also among the higher and learned. They obtained the favor and protection of Margaret, Queen of Navarre, sister to Francis I, and found patrons in several of the Reformed churches. They called themselves Libertines and Spiritual Brethren and Sisters. Their system was pantheistic and antinomian. From being a mere dogma, it degenerated into open and avowed sensualism. Calvin sternly denounced their principles, and the sect left France, took refuge in the Netherlands, and at last entirely disappeared. 2. A party in Geneva, opponents of Calvin, were also called Libertines, but they had only the name in common with the above. These Libertines were in general the opponents of the policy and theology Calvin strenuously enforced and defended; but they were formidable enough to raise an insurrection in Geneva on May 15, 1555. Their leaders being exiled or imprisoned, the power of the party was broken. 3. This name in England was given to the early Anabaptists about the middle of the sixteenth century. See ANABAPTISTS.

LIBERTI'NUS, LIBER'TUS (Lat., from *liber*, free). Names given by the ancient Romans to the manumitted slave. See MANUMISSION; SLAVERY.

LIB'ERTY. A city and the county seat of Clay Co., Mo., 14 miles northeast of Kansas City, on the Chicago, Burlington, and Quincy, the Chicago, Rock Island, and Pacific, the Kansas City, Clay County, and St. Joseph, and the Chicago, Milwaukee, and St. Paul railroads (Map: Missouri, B 2). It is the seat of the Liberty Ladies College (nonsectarian), opened in 1890, and of the William Jewell College (Baptist), opened in 1849, and contains a Carnegie library and an Odd Fellows Home. The city has considerable trade in the farm produce and live stock of the adjacent region, and some manufactures, principally of flour and vacuum cleaners. The water works and sewer system are owned by the municipality. Pop., 1900, 2407; 1910, 2980.

LIBERTY, CLAIM OF. See CLAIM.

LIBERTY, RELIGIOUS. The inherent right of the individual to form his religious opinions according to the dictates of his own conscience, and to give outward expression to them in the form of public worship independently of all restraint or coercion upon the part of the state. It includes more than mere freedom of conscience, which in reality is beyond the control of the civil power. It includes also more than mere toleration, which simply concedes for the time the right of the individual to worship as he pleases—a concession which implies the superiority of an established church, and which may be withdrawn at the will of the sovereign granting it. Religious liberty implies the equality of all in the matter of worship, while the principle upon which toleration is granted denies this idea. Religious liberty is frequently characterized as one of the absolute, inalienable, or natural rights of the individual, while toleration is a concession emanating from the benevolence of the sovereign.

Among the nations of antiquity the idea of religious liberty was almost totally lacking. In Egypt, Assyria, Babylon, Persia, and Syria, the individual was subject to the will of the King in religious as in civil matters. In the Roman Empire worship of the state religion was obligatory upon every subject. The Christian religion was tolerated merely by many of the emperors during the early centuries of the Christian era. There were spasmodic persecutions by Nero, Domitian, Hadrian, and others; but it was not until the reign of Diocletian that a determined effort was made to exterminate the Christian religion. By his order all Christian assemblies were forbidden, all churches were to be destroyed, all Christian books to be burned, and all Christians who refused to adopt the state religion were to suffer death. Early in the fourth century a formal act of toleration was granted to the Christians by the Emperor Galerius, but it was expressly enacted that they were to respect the religion of the state. This was soon followed by the conversion of the Emperor Constantine, and his promulgation, in 313, of the celebrated Edict of Milan, which granted the fullest toleration of religious worship to all persons. This was shortly followed by an edict prohibiting heathen worship and establishing Christianity as the state religion of the Empire.

Throughout the Middle Ages the question of religious liberty scarcely arose. The teachings of the Roman Catholic church were unquestioned and its authority universally recognized in most of the countries of Europe. But when the Albigenses in southern France refused to accept the Catholic doctrines, they were condemned as heretics and the sect exterminated. To prevent recurrences of a similar kind, decrees were issued by the sovereigns of western Europe against all who refused to accept the Christian faith as understood by the Catholic hierarchy. Where the domination of the papal authority was displaced, as in England under Henry VIII, it was superseded by the royal authority, not less intolerant. Thus, we find Henry VIII persecuting those who, on the one hand, acknowledged spiritual allegiance to the Pope and those, on the other hand, who, while acknowledging Henry's supremacy as head of the English church, yet denied certain of the Roman dogmas. Nor did the Reformation introduce the principle of religious liberty into Europe. For, while the Protestant denied the authority and much of the doctrines of Rome, he nevertheless insisted upon unity of faith as essential to the integrity of the state. According to the maxim *Cujus regio, cujus religio*, it was the right and duty of the prince to choose a religion for his subjects and require them to worship it. It followed that it was his duty to root out heresy and punish Nonconformists. Thus, Servetus was burnt at the stake in Geneva, which was under Calvin's control, for denying the doctrine of the Trinity; the Covenanters were hunted down and slain because they could neither accept Episcopacy nor the National Kirk; and the Pilgrims emigrated to the wilds of America because they would not conform to the Anglican faith. The theory which then obtained was that, religion and morality being the basis of the state, it became the first duty of a wise prince to establish a national religion, and it was believed that the existence of two religions in the state would endanger its security.

Strangely enough, those who fled to America to escape religious persecution brought with them the Old World ideas of religious intolerance. Everywhere in New England except in Rhode Island dissent from the "established order" of worship was looked upon as sedition against the state and sin against God. Jesuits, Baptists, and Romish priests were punished by imprisonment or banishment, while several Quakers were publicly hanged on Boston Common. Practically the same policy was followed in the colonies planted in the South. The Puritan insisted upon conformity because he wished to make the state a religious unit; the Cavalier required it because the Church was a part of the civil polity. In the Colony of Rhode Island state and church were absolutely divorced from the first, and the individual left entirely to the teachings of his own conscience. In the Catholic Colony of Maryland religious toleration existed for a while, except as to Jews, Mohammedans, and other non-Christians; but eventually the Church of England was established by law. In New York and New Jersey strenuous efforts were made by the English authorities to impose the Church of England in place of the Dutch Reformed church, but without success. In Georgia liberty of worship existed until near the Revolution, when the Church of England was established as the state religion. In Pennsylvania and Delaware, as in Rhode Island, no state church ever existed.

The framers of the Federal Constitution inserted a provision in that instrument declaring that no religious test should ever be required as a qualification to any office or public trust under the United States. Doubtless they had in mind the celebrated Test and Corporation acts of the Stuarts, enforced in all the Colonies except Rhode Island and in some of them down to the Revolution. Even in tolerant Pennsylvania all public officers had to declare and subscribe to their disbelief in transubstantiation, the adoration of the Virgin Mary, and the sacrament of the Romish mass as superstitious and idolatrous. There was considerable opposition to the adoption of the Federal Constitution on account of its lack of a provision excluding non-Christian sects from the right to hold office, and also of a provision prohibiting Congress from creating a state religion; and the first amendment to the Constitution was one prohibiting Congress from making any laws respecting an establishment of religion or prohibiting the free exercise thereof. The States, however, were left free to establish a church and restrict religious worship as they saw fit. As a matter of fact, all of the States which maintained established churches during their colonial existence have disestablished them and inserted in their constitutions provisions granting religious liberty. A complete divorce of church and state was not accomplished in some of the Commonwealths until after the adoption of the Federal Constitution. It came finally in Virginia through a decision of the Court of Appeals in 1840; in Delaware and Connecticut through the adoption of new constitutions in 1818 and 1831; in Massachusetts through an Act of the Legislature in 1833; in Pennsylvania and South Carolina through the adoption of new constitutions in 1790; in Vermont and New Hampshire through acts of the Legislature passed in 1807 and 1819. At the present time 26 of the State constitutions declare it to be the privilege of "every man to worship God according to the dictates of his own conscience." Eleven declare that the "free enjoyment of religious sentiment and forms of worship shall ever be held sacred." Five make it the duty of the Legislature to pass laws for the protection of religious freedom. Nineteen declare that "no human authority ought to control or interfere with the rights of conscience," while nine ordain that "no person may be molested in person or estate on account of religion." Most of the State constitutions forbid compulsory attendance or support of any church; many of them forbid the appropriation of money for the support of sectarian institutions, although New Hampshire, Massachusetts, and Missouri allow the parishes to provide for the support of religious teachers; while nearly all in one form or another forbid religious tests for office. Curiously enough, however, eight States, some of which forbid religious tests, disqualify from public office all who deny the existence of a Supreme Being or a future state of rewards and punishments.

While almost complete liberty of worship now exists in the United States, it is recognized that religious liberty, like the liberty of the press and speech, may be abused to the injury of others and the detriment of the public morals. Thus, the constitutions of many of the States provide for a guarantee against abuse by declaring that liberty of conscience shall not be construed to excuse acts of licentiousness or justify practices inconsistent with the peace and safety of the State, and the Supreme Court has held that liberty of worship as understood in the United States extends only to relations between the individual and an extramundane being, and not to relations among individuals themselves. On this ground the court held that a law of Congress prohibiting the practice of polygamy was not an infringement of religious worship.

The influence of the American idea of religious liberty has been very powerful over Europe and elsewhere. In France different religious denominations are treated equally, all receiving state aid. In Germany liberty of worship is allowed subject to certain restrictions upon the right of assembly. In England the Anglican church is still the established faith, but religious tests for office, except in the case of the crown, have been abolished.

LIBERTY (OF. *liberte*, Lat. *libertas*, from *liber*, free), STATUE OF. A colossal bronze statue executed by Frédéric Bartholdi, a French sculptor, and presented to the people of the United States by the people of France. It stands on Bedloe's Island in New York Harbor. The gift was designed to commemorate the hundredth anniversary of American independence. It was, however, not placed in position until 1885, and it was dedicated Oct. 23, 1886. The statue represents a female figure holding a torch aloft and is of most impressive aspect to ships entering the harbor. It is the loftiest statue in the world. The figure measures 111 feet in height, and to the extremity of the torch 151.41 feet. The torch is 305 feet, 11 inches above mean tide. Forty persons can stand within the head, to which there is access by a staircase inside of the statue; a branch staircase leads into the extended arm. The torch is equipped with a very powerful electric light. The foundation was contributed by subscription among the American people.

LIBERTY BELL. The bell which first rang to celebrate the adoption of the Declaration of Independence, July 4, 1776. It was brought to Philadelphia from England in 1752 and was recast in April and again in June, 1753, when the words "Proclaim liberty throughout all the land, unto all the inhabitants thereof" (Lev. xxv. 10) were inscribed on it. For many years it was rung annually on the Fourth of July, but on July 8, 1835, while being tolled in memory of Chief Justice Marshall, it was broken. It now hangs in the hallway of the old State House in Philadelphia.

LIBERTY BOYS. A familiar name for the Sons of Liberty of the American Revolution.

LIBERTY CAP. A conical, close-fitting cap with the top drooping forward, sometimes known as the Phrygian cap from the fact that such a headdress was commonly worn by the ancient Phrygians. A cap of this sort was a token of freedom among the Greeks and Romans, and the placing of it upon the head of a slave was one of the ceremonies attending his manumission. The murderers of Cæsar carried through the streets a liberty cap on the end of a pole; and coins were stamped with a cap between two daggers at the command of Brutus and Cassius. The symbol was also adopted in the Netherlands at the time when they threw off the yoke of Spain: but it is most famous—as the *bonnet-rouge* of the revolutionists—for its connection with the French Revolution. Louis XVI, on June 20, 1792, was forced to put it on his head as a token of his sympathy with the popular demands. In August of the same year it was officially adopted as the badge of a "patriot." The cap has also appeared on the head of the Goddess of Liberty or on a pole by her side on some of the coins of the United States, and it appears in the coats of arms of several foreign countries.

LIBERTY, EQUALITY, AND FRATERNITY. The watchword of the French Revolution, denoting the salient principles of the teachings of the social philosophers of the eighteenth century. The phrase may be conceived as the political confession of faith of the first French Republic, and lay at the basis of its institutions in much the same sense as the similar phrase in the Declaration of Independence underlies the recognition of the sovereignty of the people in the Constitution of the United States. See Natural Law.

LIBERTY HALL. The name given by Squire Hardcastle to his house in Goldsmith's *She Stoops to Conquer*, and a proverbial term for a house where guests are free to follow their own inclinations.

LIBERTY OF THE INDIVIDUAL. Individual liberty has reference to a sphere of action in which the individual is referred to his own will so far as the limitations of government are concerned. Viewed from one side, it consists of *immunities* or exemptions from the operation of governmental power; looked at from the other side, it consists of positive *rights* which it is the duty of the government to enforce and protect. While the content of individual liberty varies among races, the Western nations have reached a substantial consensus in regard to its essentials. It now generally includes freedom of person and of property, freedom of conscience and its expression, freedom of opinion and its expression, subject to the restrictions everywhere imposed by the law of libel and slander, and equality before the law. Besides this sphere, which is now practically universal, a still wider realm of liberty has been created in many states and is embodied in their constitutions. In the Constitution of the United States it includes the right of assembly for the purpose of petitioning the government for redress of grievances, the right of bearing arms, immunity from the quartering of soldiers in one's house, immunity from unreasonable searches, immunity from prosecution by the government except in accord with usages and procedure which have been in common use from time immemorial. In states having the federal system of government it is necessary to provide a double sphere of liberty for the individual—one against the operation of the general government and one against the operation of the local governments. In the United States the great source of individual liberty is the Constitution. In fact, the American Constitution is quite as much an instrument of liberty as of government. The national Constitution and all of the State constitutions, with one or two exceptions, have elaborate bills of rights in which a sphere of liberty is marked out and upon which the government is forbidden to encroach or to permit any individual to encroach. The same feature appears in modified form in the German Imperial, the Swiss, and the Prussian constitutions, but not in the constitution of the French Republic or those of the remaining European states. The chief guarantee of individual liberty in the United States is the power of final interpretation of the Constitution by the Supreme Court, and the power of Congress to impeach and remove all civil officers of the United States.

LIBERTY OF THE PRESS. In English and American law, the right of printing and publishing what one will, subject only to the penalties of the ordinary law of the land for making an improper use of the liberty. These legal restrictions are (1) that the publication shall not be libelous, (2) that it shall not be such as to incite to sedition or treason, and (3) that it shall not be blasphemous. From this it will be seen that there is no such thing as liberty of the press in the broad sense in which the phrase is popularly understood. The unrestricted right of the citizen to say and publish whatever he pleases without fear of legal penalties, affirmed in the French constitution of 1791 (Tit. I) and in the present constitution of Belgium (Art. 18), has never in fact existed anywhere. The provision of the American Constitution (Amdts., Art. I) which forbids Congress to make any law "abridging the freedom of speech or of the press," does not exempt citizens from the penalties of the ordinary law either of the United States or of the several states for an abuse of the liberty. Its only effect is to preclude the enactment of laws setting up a censorship or permitting the suppression of newspapers or other publications, and this is, indeed, the sense in which the expression "liberty of the press" is to be understood. The liberty is a liberty to publish what one will and take the consequences, and these consequences are to be determined, not by any arbitrary administrative authority nor by any special tribunal under special "press laws," but by the ordinary law of the land administered by the ordinary tribunals of justice. The distinction, then, between governments which do and those which do not concede full liberty of discussion in what may be called the Anglo-American sense is that the former exercise no supervision over the publication of opinion, while the latter do. The actual liberty of expression in the sense of freedom from punishment for its exercise need be no greater in the one case than in the other, though in practice it has been found that the power of suppressing opinion by censorship or otherwise is more likely to be abused by a government, i.e., more likely to be arbitrarily and rigorously exercised, than the power of punishing for an abuse of the privilege. Accordingly the liberty of the press has been much more of a reality in England and the United States, imperfect as it still is even in those countries, than in countries where the policy of suppression prevails. This policy prevailed in France, notwithstanding the brave words of the constitution, till 1881, when the last press law was repealed, and it still obtains in most other continental countries. Even in England the policy of governmental restriction persisted till the eighteenth century. In the two preceding centuries printing was a government monopoly or a privilege granted to certain licensed individuals and practiced under regulations put forth by the Star Chamber. The censorship surviving the fall of the Star Chamber was legalized by Act of Parliament in 1662 (13 and 14 Car. II, c. 33) and was not abolished till 1695. "In England, as on the Continent, the book-trade was a monopoly, the censorship was in full vigor, the offenses of authors and printers were treated as special crimes and severely punished by special tribunals."

Most governments, even of highly civilized states, are still under the influence of the notion, which was once universal, that the free expression of opinion is incompatible with the safety and good order of the state and that these require the suppression of free criticism of the government or of ruling persons, as well as of news which might have the effect of exciting or agitating the public mind. This attitude has gradually been modified by the growing conviction that an intelligent and informed public opinion is less dangerous to the state than an ignorant one and that the intellectual and moral loss resulting from the suppression of free criticism and discussion of public affairs and the free expression of opinion outweighs the dangers of publicity.

As has been said above, the best examples of liberty of the press are furnished by England and the United States, where the question of an alleged abuse of the liberty is tried by the ordinary law and by the ordinary process of the courts. As this process involves the trial by a jury of the question of fact involved, we have the situation, summed up by an eminent legal authority: "Freedom of discussion is, then, in England little else than the right to write or say (i.e., to publish) anything which a jury, consisting of twelve shopkeepers, think it expedient should be said or written. Such 'liberty' may vary at different times and seasons from unrestricted license to very severe restraint, and the experience of English history during the last two centuries shows that under the law of libel (to which may be added that of treason and of blasphemy) the amount of latitude conceded to the expression of opinion has, in fact, differed greatly according to the condition of public sentiment." (A. V. Dicey, *The Law of the Constitution.*) Such is the liberty of the press in ordinary times. In time of war, however, or of widespread sedition, the right is much restricted. Whenever in a civilized state a state of siege or martial law (state of war, *Kriegeszustand*) has been proclaimed and the ordinary jurisdiction of the courts superseded by military law, liberty of the press, along with the other personal rights secured to the individual by the ordinary law, disappears. The censorship of the press, which was so drastically enforced in England as well as in continental countries during the war that began in 1914, and the suppression of newspapers publishing criticisms of governmental action or unauthorized news, are the usual incidents of such a situation. *Inter arma leges silent.* See LIBEL; NEWSPAPER.

Schroeder, *Methods of Constitutional Construction* (ib., 1914).

LIBERTY PARTY. A political party which existed in the Northern States of the American Union from 1839 to 1848 and was the first regular organization that attempted to oppose slavery by political means. The abolitionist followers of William Lloyd Garrison (q.v.) had adopted the doctrine of nonparticipation and nonresistance. With this policy the practical antislavery men were not satisfied, and after seeing the futility of their attempt to make their influence felt by interrogating candidates for office as to their position on the slavery question, they concluded that a party organization was the only rational means of accomplishing anything of value. This view, particularly strong in western New York, Ohio, and Michigan, found perhaps its ablest advocate in Myron Holley, who at a meeting of the American Antislavery Society in vain introduced and advocated a resolution declaring that "it was time to form a new political party" and proposed the nomination of candidates for the presidency and vice presidency. Within a month (Nov. 13, 1839), at a local convention at Warsaw, N. Y., Holley was instrumental in securing the nomination of James G. Birney (q.v.) and Francis J. Lemoyne as candidates for President and Vice President respectively. A "national" convention, composed mostly of New York delegates, and held at Albany, April 1, 1840, confirmed Birney's nomination, nominated Thomas Earle for Vice President, and adopted the name of Liberty party. But the enthusiasm of the "Tippecanoe and Tyler too" campaign retained in the Whig ranks most of those whose antislavery views might otherwise have led them to support the new party's ticket; and despite the fact that an active campaign was carried on, the ticket polled a total of only 7059 votes, 2798 of which were cast in New York. Disappointing as was the result, the Liberty party leaders did not lose heart, but at once set about preparing for the campaign of 1844. On May 12, 1841, the first really national convention of the party was held in New York, in which all the New England States, New York, Pennsylvania, New Jersey, Ohio, and Indiana were represented. Birney and Thomas Morris were nominated as the party's candidates for 1844, and a complete national organization was planned. The party at this time was made up of the more moderate abolitionists, who held that the Constitution gave the general government no power to abolish slavery in the States, and proposed only its abolition in the District of Columbia and the Territories, through Federal action, leaving the several States to act as they could be persuaded. The next convention was held in Buffalo on Aug. 3, 1844. A slight movement within the party favorable to Clay, who had pronounced against Texan annexation on the ground that it would involve the United States in a war with Mexico, was checked by the publication of a letter written by Clay in which he had said that he would "be glad to see" Texas annexed some day. The Liberty men were moreover strongly opposed to Clay personally. This turned the scale, and the nominations of Birney and Morris were confirmed. At the ensuing election the Liberty party polled 62,300 votes, 15,812 of them in New York, almost all of them drawn from the Whig party. The loss of these votes assured the election of Polk and Clay's defeat. Clay's chances were injured outside the Liberty ranks by his equivocal attitude on the annexation of Texas. The first actual effects of the Liberty party's action, therefore, were the election of Polk, the annexation of Texas, and the addition of a considerable area of new slave territory to the Union. Their last great effort made in the elections of 1846 was attended with no success. Their last national convention, held in Buffalo, Oct. 20, 1847, nominated John P. Hale and Leicester King for President and Vice President, but the movement towards amalgamation with the new Free-Soil party (q.v.) had already begun. The nominees withdrew after Van Buren's nomination, and, except for the continued activity of a small number who had adopted the view that slavery could be abolished under the Constitution by a simple act of Congress, the Liberty party ceased to exist.

Bibliography. The best account of the Liberty party is contained in T. C. Smith, *History of the Liberty and Free Soil Parties in the Northwest* (New York, 1897). Consult also, J. D. Hammond, *History of Political Parties in the State of New York* (Cooperstown, 1846); B. F. Morris, *Life of Thomas Morris* (Cincinnati, 1856); William Birney, *James G. Birney and his Times* (New York, 1890); A. B. Hart, *Salmon P. Chase* (Boston, 1899), in the "American Statesmen Series"; McLaughlin and Hart (eds.), *Cyclopedia of American Government*, vol. ii (New York, 1914).

LIBERTY TREE. 1. An elm in Boston, upon which the citizens hung the effigies of the British stamp distributor and other unpopular persons during the excitement connected with the Stamp Act. The tree stood on Washington Street, and is recalled by an appropriate device on the building which occupies its site. 2. A Revolutionary War ballad by Thomas Paine (1775), published in the *Pennsylvania Magazine.*

LI′BER VER′ITA′TIS (Lat., Book of Truth). A series of original drawings made by Claude Lorrain (properly Gelée, q.v.) for the purpose of protection against the imitation of his paintings by others. The work, engraved by Richard Earlom, was published by John Boydell in 1707.

LIBIDIBI, lē′bē-dē′bē. A tropical tree whose pods are used in tanning. See Divi-Divi.

LIBIN, lē′bĭn, S., pseudonym of Israel Hurwitz (1871-). A popular Yiddish writer, born in a little Russian town (Gorki) in the Government of Mogilev. Intended for a rabbi, he received the traditional orthodox Jewish education. At 14, however, the boy set about acquiring a secular education by self-study. In 1891, after serving a trade apprenticeship, he left Russia for England and soon afterward came to the United States and settled in New York. Libin's literary career began in 1894 with a short sketch ("Spring") published in the *Arbeiter Zeitung*, a Jewish Socialist weekly. Numerous other sketches appeared from time to time, but it was not until his first successful play, *Broken Hearts*, was produced (1905) that he attracted general attention. Thereafter he was a constant contributor of short stories, plays, and novels to Jewish-American newspapers chiefly the *Vorwarts.* Of his shorter pieces five volumes have so far been published (*Collected Sketches*, 1902, 1907, 1910; *Selected Works*, 2 vols., 1915). His plays, on which his greatest popularity rests, numbered 35 in 1915. Among the better known are *The Belated Wedding* (1900), *The Jewish Medea* (1901), *Broken Hearts* (1905), *The Dreamer* (1909), *The Abyss* (1911), *A Mother's Revenge* (1913), *The Power of Passion* (1914). His several novels are artistically inferior to his best plays and sketches. A realist, like all his contemporaries among Yiddish writers, Libin draws his themes from the Ghetto. The finely contrasting humor and pathos of his best work have brought him recognition as one of the greatest Yiddish story-tellers of his day and as a playwright second only to Jacob Gordin (q.v.), by whom he, in common with all present-day Yiddish playwrights, has been influenced.

LIB′ITI′NA. An old Italian goddess of the dead, and of funerals, identified by the ancients both with Venus Lubentia (or Venus Lubentina or Venus Libitina) and with Proserpina. The identification with Proserpina was natural enough; that with Lubentia arose because both *Libitina* and *Lubentia* were connected by the Romans with *libido*, pleasure, voluptuousness, and from the fact that in the grove about the temple of Libitina was a shrine also of Venus. From her temple, situated, perhaps, on the Esquiline, all the necessary apparatus for funerals had to be bought, and a piece of money was deposited there for every person dying in Rome. Undertakers were called *libitinarii*, and the gate of the amphitheatre through which the dead were removed bore the name of Porta Libitinensis. Libitina sometimes in poetry stands for "death" or "the grave." Venus Lubentina was perhaps an Italian goddess of gardens. Consult Georg Wissowa, *Religion und Kultus der Römer* (2d ed., Munich, 1912).

LIBMANÁN, lēb′mȧ-nän′. A town of Luzon, Philippines, in the Province of Ambos Camarines (Map: Philippine Islands, D 4). It lies near the mouth of the Polanluna river. It has a post office and a telegraph station. Pop., 1903, 17,416.

LIBOCAN, Hájek of. See Hájek of Libocan.

LI′BOCE′DRUS (Neo-Lat., from Gk. *λίβος*, *libos*, tears + *κέδρος*, *kedros*, cedar). A genus of evergreen trees, belonging to the Pinaceæ, resembling the arbor vitæ, but differing in the structure of the cones, the scales not overlapping as in that tree. There are two species in New Zealand, *Libocedrus bidwellii* and *Libocedrus doniana;* two in the mountains of Chile, *Libo-*

cedrus chilensis and *Libocedrus tetragona;* one in the Pacific Sierras of the United States, growing usually at an elevation above 4000 feet; one in China, *Libocedrus macrolepis;* and one in New Caledonia, *Libocedrus austro-calidonicus.* The Western United States species was named by Torrey *Libocedrus decurrens,* from the fact that the bases of the small scalelike leaves are decurrent upon the stem. The tree attains a height of from 120 to 140 feet, and a trunk from 6 to 8 feet in diameter, without branches for 80 to 100 feet. It is found from Oregon to Lower California. Its beautiful glossy green foliage and its graceful form when young make it one of the finest of ornamental evergreens. It has been confounded with the *Thuya gigantea,* but its decurrent leaves make an easy distinction. In California it is called white cedar. Its wood, of a yellowish color, surpasses redwood in durability, and is valuable for various purposes.

LIBOURNE, lē'bo͞orn'. The capital of an arrondissement in the Department of Gironde, France, at the confluence of the Isle with the Dordogne, 22 miles east-northeast of Bordeaux (Map: France, S., D 4). Its ancient features include the fourteenth-century clock tower, the fifteenth-century church of St. Jean Baptiste with a spire 232 feet high, and a sixteenth-century town hall. Its modern institutions comprise a communal college, a school of hydrography, a museum, a library, a botanical garden, and a theatre. The surrounding district abounds in vineyards. The chief manufactures of Libourne are liquors, sugar, woolen goods, machinery, cooperage, and printing; it carries on a considerable trade in local manufactures and agricultural products by the river, which is navigable for vessels of 14 feet. Pop., 1901, 19,175; 1911, 15,350.

LI'BRA (Lat., balance). The seventh sign of the zodiac, its conventional symbol being ♎. At the first point of Libra, or, as it is often called, the *autumnal equinox,* the ecliptic passes across the equator to the Southern Hemisphere. Libra is also the name of a constellation situated immediately south of the celestial equator and east of Virgo. Its chief object of interest is the globular cluster *Messier 5,* which is rich in variable stars.

LI'BRARIES. A term applied alike to buildings designed to contain books and to the books deposited in these buildings. In the present article it is used chiefly in the latter sense.

History, Ancient. Though there were libraries in ancient times in Egypt, no extensive remains of these collections have been found. From very early days Babylonia was the seat of a learned and literary people, and almost every important temple contained its library of clay tablets in cuneiform writing, carefully shelved in regular order. Such a library was found at Nippur, in 1901, in the great temple of Bel, which was destroyed in the Elamite invasion (c.1782 B.C.). It was from the treasures of such libraries that King Asurbanipal of Assyria, in the seventh century B.C., caused copies to be made for the great library, consisting probably of over 10,000 works, which he gathered in his palace at Nineveh. The tablets here found by Layard and his successors contain history, science, religion, grammars, and dictionaries in the original languages of Babylonia and in translation.

Among the Greeks private libraries doubtless existed during the fifth and fourth centuries B.C., and there may be some truth in the stories of the collection of books by the earlier tyrants, such as Pisistratus and Polycrates; but these were of moderate size, even the library of Aristotle probably containing only a few hundred rolls, and of their character and administration we know practically nothing. It is with the founding of the Alexandrian Library (q.v.) by the first of the Ptolemies that the history of the great Greek libraries begins. At the time of their greatest development the twin libraries at Alexandria probably contained between 600,000 and 700,000 volumes or rolls, all carefully arranged and catalogued. In the Civil War Julius Cæsar burned the shipping in the harbor, and in the conflagration thus started the larger library was destroyed. The library of Pergamum in Asia Minor, a formidable rival to that of Alexandria, was founded probably by Attalus I and was largely increased by the fostering care of his successors. It was ultimately removed to Alexandria, being sent by Antony as a gift to Cleopatra, with a view to replacing the books destroyed under Cæsar. At the time of this transference it contained, according to Plutarch, 200,000 volumes.

At Rome interest in literature developed slowly, and the first important libraries appear to have been those gained as the spoils of war; thus, we are told that the library of the kings of Macedon was brought to Rome by Æmilius Paulus (167 B.C.). In the first century B.C. there were some notable private collections, as that of the grammarian Tyrannion, estimated at 30,000 rolls, and the carefully selected and valuable collection of Atticus, the friend of Cicero. Cæsar is said to have planned a public library; and Pliny states that C. Asinius Pollio (39 B.C.) erected from the spoils of his Parthian victories the first public library in Rome, in the temple of Libertas; but according to Plutarch this honor should be given to Lucullus. Another public library was established by Augustus on the Palatine, in connection with his new temple of Apollo. This was divided into Greek and Latin sections. Another was placed by the same Emperor in the Portico of Octavia. Tiberius and later emperors continued the foundation and maintenance of public libraries. Especially famous was the Ulpian Library, established by Trajan, which soon surpassed all others in Rome and was later removed from the Forum of Trajan to the Baths of Diocletian. The number of public libraries in Rome is said to have reached 28 by the fourth century. Nearly 1700 manuscripts and fragments of manuscripts have been found in a library room at Herculaneum, about 400 of which have been more or less unrolled and deciphered. And in the Roman provincial towns throughout the Empire public and private libraries were numerous. In fact, the library facilities of the Roman world in Imperial times probably surpassed those of modern Europe before the middle of the eighteenth century.

In the ancient libraries the books, usually rolls of papyrus, were kept in closets, in somewhat small rooms, which, however, seem to have been arranged for the use of the books. Catalogues were prepared, and those of Alexandria were valuable sources for literary history. The librarian was commonly a distinguished scholar and in later times seems to have ranked as an important public officer. The first librarian of whom we have any record was a Babylonian named Amil-anu, who lived about 1600 B.C., one of whose signet cylinders is in the British Museum. Nehemiah is said to have founded a library, and references in the books of Samuel and Kings to other books imply some collection in which these works might be found.

As the Christian Church came to possess a distinct literature, not only were small collections established in the important churches, but libraries of some size devoted largely to Christian writings were founded. Eusebius mentions an early Christian library established by the martyr Alexander, Bishop of Jerusalem, who died 250 A.D. St. Pamphilus, another Christian martyr (309 A.D.), founded at Cæsarea a public library which grew to about 30,000 volumes, chiefly theological, and which is said to have been destroyed by the Arabs in the seventh century. St. Jerome had a large library and made frequent use of that at Cæsarea. St. Augustine, on his deathbed (430 A.D.), requested that the library of the church at Hippo and all his manuscripts should be carefully preserved. In the early monasteries of Tabenna, founded by Pachomius, in the depths of the Thebaid in Egypt, there was a library in every house, showing the early connection between monasticism and libraries.

Julian the Apostate (363 A.D.) founded libraries of a different character, upon which he inscribed the words: "Some love horses, some birds, others wild beasts, but from boyhood I have been possessed with the desire of acquiring and owning books." Constantine the Great founded (336 A.D.) a library at Constantinople, which at his death is said to have contained 6000 volumes; it grew under Julian and Theodosius the Younger to 120,000 volumes. In it was deposited the only authentic copy of the proceedings of the Council of Nice, and among its curiosities were a manuscript of Homer, 120 feet in length, written in letters of gold on serpents' skin, and a copy of the Four Gospels bound in plates of gold weighing 15 pounds and enriched with precious stones. This library was destroyed by fire under Zeno (477 A.D.). A later collection, extending to 33,000 volumes, is said to have been destroyed by Leo III "the Iconoclast" (730 A.D.). The triple fire at the capture of Constantinople by the Crusaders, in 1203, eclipsed all previous ones in destructiveness. Two hundred and fifty years later came the final disaster of the Ottoman conquest. Despite all these losses, possibly through some of them, the great libraries of Europe owe to Constantinople some of their choicest treasures.

History, Mediæval. Through the Middle Ages books and learning were chiefly preserved by the monasteries, especially those of the Benedictines, beginning at Monte Cassino (530 A.D.). Each Benedictine house instituted first a library, then the *scriptorium*, or writing room, where manuscripts were copied for its own use, for sale or exchange, and lastly the school, open to all who desired instruction. Many famous libraries of Europe had their nuclei in these Benedictine collections. Notable among these are the libraries of Monte Cassino, Bobbio, Fleury-on-the Loire (c.650), Corbie (662), Hersfeld, Ratisbon, Corvei (q.v.), Reichenau (724), Fulda (774), Saint-Gall (820), and Clugny (910). In addition to the Benedictines, the Augustinians and the Dominicans were distinguished for their care for libraries. Charlemagne established libraries in his cloister schools at Aix-la-Chapelle and Tours, to which Alcuin brought the training he had secured at St. Mary's in York, England.

England is indebted to the Benedictines for her earliest library, that of Christ Church, Canterbury (596), and for St. Peter's of York, St. Cuthbert's at Durham, and those at Peterborough, Wearmouth (647), Bury St. Edmunds, Reading, and St. Albans. The Franciscans had a considerable library at Oxford, to which Adam de Murisco left his books (1253). The Bodleian at Oxford was opened in 1602. The library of the University of Cambridge dates from 1475. On account of the scarcity and costliness of writing materials, and because of the prevailing ignorance and neglect of letters, none of these monastic libraries attained to any great size, 2000 volumes being about the largest number recorded. Nevertheless, the monastic libraries performed an incalculable service in the preservation of Latin and (in part) Greek literature.

History, Modern. In Germany, with the fourteenth century came the establishment of libraries in connection with the new universities, as those at Prague (1348), Heidelberg (1386), Leipzig (1409); and the first public town libraries, the outcome of humanism, at Ratisbon (1430), Vienna (1440, opened to the public in 1575), and Frankfort (1484). The zeal for letters which so marked the Renaissance led to the formation of great private collections which were frequently made the bases of public libraries as, e.g., the library presented to Durham College by Richard de Bury, and the great Medicean Library founded by Cosimo de' Medici at Florence. The suppression of the monasteries after the Reformation in Protestant countries gave an impulse to the foundation of the royal, ducal, and town libraries. Many important ones were established in the eighteenth and nineteenth centuries: Göttingen (1737), Bonn (1818). All the universities of Germany have large libraries, and in addition the royal libraries at Berlin, Vienna, Dresden, Munich, etc., are among the most notable collections in the world. No other country can show such well-equipped libraries for scientific research as those of Germany and Austria at the present day.

Spain, with its university at Palencia (1212), which removed to Salamanca in 1254, takes a very early place in library history. The National Library at Madrid is the largest in the country, having 700,000 volumes.

The famed Corvina, established by Matthias Corvinus, King of Hungary (c.1460), was probably the largest and finest collection of manuscripts ever made in Europe, reaching over 50,000 volumes, but its treasures were dispersed by the Turks in 1527; scattered specimens are to be found in more than 30 of the libraries of Europe. The Royal Library at Copenhagen, dating from 1479, the largest of Scandinavian libraries (over 800,000 volumes), is specially strong in Icelandic literature and has a fine collection of Persian manuscripts.

The first public library in Italy was founded at Florence, in 1437, on a bequest by Nicoli, the Florentine Socrates, of his own collection of 800 manuscripts. Cosimo de' Medici erected a building for it in 1441, and later, under his grandson, Lorenzo de' Medici, it acquired the name of Laurentian Library. With the expulsion of the Medici at the close of the fifteenth century the collection passed into the possession of a monastery. Later Leo X bought it, and in 1521 Cardinal Giulio de' Medici restored it to the city and housed it in a building erected by Michelangelo. This is one of the richest and most valuable libraries in the world, only surpassed (among Italian libraries) in manuscript treasures by the Vatican. Although the library of the popes can be traced back to a remote antiquity, it was Nicholas V who founded the present Vatican Library in 1447 and left it at his death enriched with 9000 manuscripts. In 1588 its present building was erected by Sixtus V. In addition to a long series of notable acquisitions of valuable manuscripts the famous Urbino Library was acquired for it in 1658. Queen Christina of Sweden enriched it with a splendid collection of manuscripts and books. In 1746 the Ottoboni collection of 3862 German and Latin manuscripts was added. During the nineteenth century the process of adding great collections had gone on, the most impressive purchase being that of the entire Barberini Library. There are over 31,000 Latin manuscripts, and the Greek and Oriental number over 4000 each. Moreover, there are upward of 400,000 printed books, many of the greatest rarity. Since the pontificate of Leo XIII the Vatican Library has been very freely open to scholars. Italy is exceedingly rich in libraries of historical interest; her university libraries contain many manuscripts and incunabula. Among the famous collections may be named the Ambrosian Library (q.v.), at Milan, founded in 1602; the Vittorio Emanuele, at Rome; the National Central, at Florence, formed by the union of the well-known Magliabechiana and Palatina; and the National of St. Mark at Venice. The university libraries are in the main admirable, and many of the smaller libraries contain manuscripts and books of great value. The archives of Venice, complete for more than 10 centuries and numbering 15,000,000 documents are housed under a single roof. Moreover, in Italy there is a strong and growing movement for the establishing of popular circulating libraries, somewhat on the model of the smaller public libraries in the United States.

France, in the Bibliothèque Nationale, at Paris, has the largest library in the world. Charles V in 1368 had a tower in the old Louvre fitted up as a library, where he gathered 910 volumes. These were scattered during the English wars, and many fell into the hands of the Duke of Bedford and were carried to London. Louis XI made an effort to revive the library. Henry IV gave it a home in the Collège de Clermont and appointed De Thou librarian. It narrowly escaped destruction at the time of the Revolution, when two of its librarians were guillotined. In 1666 it was removed to its present building, which has been frequently enlarged to accommodate the rapidly growing collection. The library now numbers well over 4,000,000 volumes of printed books, 500,000 maps, 110,000 manuscripts, and over 1,000,000 prints. The smaller libraries of Paris include the Arsenal, founded in 1755; the Mazarin (1643); and the St. Geneviève (1624), together with those of the university and other educational establishments. Large libraries owing their origin to monastic collections and to the liberality of private persons are to be found in all the provincial cities of France. Most noteworthy are those of Lyons (1527), Aix (1705), Rouen (1809), and Bordeaux (1738). There are (1915) over 13,000,000 books in French libraries outside of Paris, chiefly in the departmental and university libraries.

Great Britain possesses in the British Museum a library second only to the Bibliothèque Nationale of France in size and probably surpassing it in the value of its contents, amounting to over 5,000,000 items of all sorts. The library dates from 1753, when the collections of Sir Hans Sloane were acquired by the nation. Before it was opened to the public, in 1759, the Royal Library of the kings of England was given to it by George II, while the private collections of George III were presented in 1823. Under the able direction of Sir Anthony Panizzi the museum took first rank among the research libraries of the world—a rank it has maintained, its accessions having been distinguished fully as much by their character as by their size. The collections of manuscripts, maps, music, and prints are among the most valuable in the world. The catalogue of printed books (to 1899) is an invaluable work of bibliographical reference, supplemented by numerous special catalogues and indexes.

In London are likewise the Patent Office Library, the National Art Library (South Kensington), and a host of smaller libraries, while in the universities and in the great commercial centres are planted libraries of size and importance, among them the Bodleian at Oxford, the University Library at Cambridge, Trinity College Library at Dublin, the John Rylands Library at Manchester, the Mitchell Library at Glasgow, the Library of the Faculty of Advocates of Edinburgh, etc. There are also in Great Britain numerous most excellent public libraries alike in the large and the smaller cities, as well as certain vigorous proprietary or subscription libraries.

The earliest library in America was that presented to the Henrico College, established by the colonists of Virginia, in 1621, destroyed at the time of the massacre the next year.

Harvard University Library was founded in 1638. In 1700 came the Public Library in New York, changed in 1754 into the present Society Library. In 1700, also, South Carolina passed the Provincial Library Law to encourage parochial libraries. Yale College Library was founded in 1701. In 1731 Benjamin Franklin founded the Library Company of Philadelphia, which he called the "mother of all North American subscription libraries." In 1800 the Library of Congress (q.v.), called in its first general catalogue the Library of the United States, was established.

The first recognition of the principle of taxation for support of public libraries was the New York District Library Law of 1835. This was not for school but for public libraries, unwisely placed in charge of school officers as a mere convenience of administration. The general plan was copied in 23 other States and without exception has proved that, while undoubtedly schools and libraries should work in the greatest harmony, the best results demand that their administration be separated. Exceptions have been only numerous enough to prove the rule. These district libraries did a beneficent work, but under their own trustees, with proper supervision and well-organized administration, the same money might have done vastly more. But the law made the needed beginning in recognizing the popular educational character and possibilities of libraries. In 1849 New Hampshire passed a law allowing towns to tax themselves for libraries. In 1850 Great Britain passed the famous Ewart

Free Libraries Act. In 1852 the Boston Public Library was founded, and for a generation led the world in showing what might be done by a municipal library. In 1853 there was held the first library convention in New York City.

From these modest beginnings the libraries of the United States have grown to be certainly more numerous and probably more efficiently organized than those of any other country. In 1914 there were more than 2000 libraries of over 5000 volumes, the greater part being supported through taxation by towns and cities. Moreover, certain of them have attained a great size; among the largest being the Library of Congress (2,253,309 volumes), the New York Public Library (2,198,000 volumes), Harvard University Library (1,565,000 volumes), Yale University Library (c.1,000,000 volumes), Boston Public Library (1,067,000 volumes), Brooklyn Public Library (764,000 volumes).

There are more than 40 American libraries containing more than 200,000 volumes each. The striking feature of library development in the United States, shown in only a slightly lesser degree in Great Britain, is the great number of small city and town libraries. Few cities of any size, and none of any importance, are without one or more libraries. Many of these smaller public libraries are admirably managed and render a distinct public service. Libraries of the research type, on the other hand, are fewer than might reasonably be expected in so large and prosperous a nation. Almost all the States have general laws permitting localities to tax themselves up to a certain amount for library purposes.

Modern Movement in the United States. It was formerly the chief duty of the librarian to get and keep books. The library was a storehouse. But the modern library is less a reservoir than a fountain. Its librarian aims to be an active, aggressive factor in popular education. He recognizes fully his duty to get and to keep, but puts far above this his greater duty to make his books useful. The old library was of interest only to the learned few. The modern public library has won a place beside the public school as an instrument of education. In public interest and support, in liberality of laws and appropriations, in magnitude of individual gifts, the modern library movement in the United States, Canada, and Great Britain far surpasses any general interest in libraries of former days or of other regions.

The birth year of active, new work of the modern library movement was 1876. In it was founded the American Library Association, a most potent national body. The *Library Journal* was established as its official organ. The Library Bureau, a centre for library enterprises, started its work. In 1876 likewise the United States Bureau of Education published a volume of essays and statistics on libraries in the United States, to which Cutter's Rules for a dictionary catalogue was added as an appendix (latest ed., 1904). In 1886 the *Library Journal* was supplemented by *Library Notes*, later replaced by *Public Libraries*, published since 1896 by the Library Bureau at Chicago.

In 1893, at the Columbian Exposition, a national comparative library exhibit, under the direction of the American Library Association, prepared by the New York State Library, was a prominent feature in the United States Building. Similar exhibits were made at the Paris Exposition of 1900, the Pan-American of 1901 at Buffalo, and the St. Louis Exposition of 1904. The *A. L. A. Catalog* of 5000 of the best books for a town library was a leading feature of the Chicago exhibit, and a second edition revised and extended to 8000 titles was published by the Library of Congress in 1904 in connection with the St. Louis Exposition.

Significant of the new part public libraries are playing has been the action of Andrew Carnegie, who, in his avowed purpose of distributing his wealth for the greatest good of his fellows, has found nothing promising so large returns as coöperation with communities which are willing to pledge themselves permanently to devote, from public funds or other sources, for the annual maintenance of a public library, one-tenth the sum given by Mr. Carnegie for a building. From 1881 to Jan. 1, 1915, Mr. Carnegie has given to public and college libraries the total sum of $62,518,517.

The clearest testimony that this library movement is accepted as educational is found in the fact that circulating, subscription, and proprietary libraries have largely given way before the tax-supported free public library, just as the private and denominational schools have been so often replaced by the tax-supported free high school. All the important steps in the historic development of the public school system have been also experienced by public libraries; among which are educating public sentiment, making libraries entirely free, giving grants and subsidies from public money, a certain degree of supervision, published reports, professional journals, training schools and classes corresponding to normal schools and teachers' classes, institutes, inspectors; and, finally, State library commissions, which will probably grow to State departments. A further step is often advocated to complete the correspondence: i.e., requiring State certification of librarians as to fitness for their duties.

The conception of the library's scope and functions has broadened rapidly in recent years. Originally the library might be used by a privileged few. Then those who paid a fee might use it. Finally it was made free to all for reference. The thought of taking any book from the older libraries was as preposterous as that of borrowing specimens or pictures from a museum. Later the favored few might borrow, then all who paid a fee, and last came the broad plan of lending freely to all. Finally the library became aggressive and reached out to secure readers as vigorously as a merchant to secure patrons. In an earnest effort to bring books within the reach of every portion of the community branch libraries have been very widely established in the large cities. The express, mail, and telephone are now used to make books more accessible. One or more books were lent to readers at a distance; then home libraries were sent out to local centres for groups of a dozen children. Traveling libraries of 50 or 100 volumes were sent to every community wishing them. The idea spread rapidly, and the "traveling library," or small collection of books, now obtains in most States, usually under the direction of the State Library Commission. The need of reaching rural homes too scattered for the larger collections led New York, in 1903, to offer to send out the house library of 10 volumes. Book wagons and cars are now in use in certain localities. Perhaps the most significant features of late years in the internal management of libraries (so far as they affect the public) are the development of reference librarians to answer questions; of the children's room and librarians devoted wholly to the needs of little people; of free access to open shelves so that all readers may have the advantages of actually handling the books; provision for those who cannot come to the main library, by means of branches and traveling libraries; and the appraisement or evaluation of books by disinterested authorities, so that a reader may have a trustworthy guide in selecting from the millions of books in existence the one best adapted to his needs.

It is generally held that the library has three functions: (1) as a storehouse of books and knowledge; (2) as a laboratory for study and research; (3) as affording sane recreation. Every library performs some one of these functions; some few attempt all three. Every public library of any size must have a reference and a lending department and general reading rooms for periodicals. It should work in close touch with the schools, but under independent trustees. It is the natural home for local collections in science, art, or history; for lectures, meetings of clubs, and all interests outside the schools which help on education and culture. Many Sunday schools find it wiser to turn their books over to the public library, where Sunday-school teachers may meet during the week, with access to books, pictures, and all facilities for study. The library field is being rapidly enlarged in various directions, particularly in direct service to the local government and to local industries.

Modern legislation aims to make it easy to establish and difficult to abolish libraries, to encourage gifts, to grant State aid to communities willing to help themselves, to collect the results of experience in library management and make them available in print and, by personal expert advice, to protect library property by stringent laws.

Types of Libraries. Because of their number and importance, public libraries are always meant in this article unless some other type is specified. Private libraries do not fall within the scope of this discussion, nor do proprietary and club libraries, as they are in a sense only larger family libraries, open only to those elected to membership.

Subscription or circulating libraries are carried on as a business and are usually open to all who pay the fees. Circulating libraries charging a small daily or weekly fee have grown greatly in numbers in the United States of recent years and are not confined to books alone, some of them including music, phonograph records, etc., in their stock. Their records and methods are naturally the simplest and cheapest, except in the case of certain institutions like Mudie's and Smith's in England, which have no exact counterpart in America.

National and State libraries have a distinct function, in addition to their daily service to the State and to scholars, in preserving for posterity the literature of their particular region or country. They are the central storehouses on which all local libraries in their field may draw when necessary. This demands large provision for storage and facilities for sending books quickly and safely to students and libraries. They should have books, pamphlets, manuscripts, and other material which because of rarity, costliness, or slight demand are seldom found in local collections. The smaller libraries have learned that the first cost of a book is seldom its chief expense. It must be catalogued, classified, shelved, cleaned, and inventoried yearly, even if never used. Libraries limited in funds cannot therefore afford to accept as gifts collections of books seldom used. The traditional conception of a library required it to keep all it could get. The immense growth in volume of books issued has enforced new ideas and has relegated the duty of preserving printed material no longer of immediate use to the national and State libraries, together with a small group of large institutions. Thoughtful observers fully realize that even public libraries, except a few great central storehouses, must abandon the plan of keeping everything, selecting up to their capacity what will be most useful and sending the rest to State or national centres, to be destroyed if found to be duplicates too common to be worth keeping.

Special Libraries. Every department of human endeavor is using the library as its laboratory, with the result that special libraries are formed in great numbers for special work. This gives libraries not only for law, medicine, theology, education, art, history, but for other distinct departments, and particularly for the active use of great industrial and manufacturing establishments, insurance companies, and the legislatures of States and cities. These libraries on special subjects are frequently independent, but they are often treated as branches of the central collection and kept under supervision of its director. The growth of specialized libraries has led to the formation of a *Special Libraries Association*, and to the publication of a monthly journal entitled *Special Libraries* (Indianapolis, Ind.).

The value of good reading in giving to any class of people information that will help them to do their work better, or inspiration and recreation which will broaden and sweeten their lives, has led to forming general libraries for special classes wherever people can be interested and command leisure to read. Owners of factories, stores, mines, and other employers have found it profitable to furnish such libraries for recreative reading on the part of their employees. Governments put them in prisons, asylums, and other institutions. Cities send them to station and engine houses of police and fire departments.

University and College Libraries. In these circulation is subordinate to reference and research work, a most important feature being to teach students how to use books and to give opportunities to handle them with a freedom formerly thought impracticable in a public library, though recent experience with open shelves has shown that the public can be trusted far more than was supposed. In modern university work every department finds the library as necessary as its laboratory. In America the university libraries have come to form a most important group in both quality and size of their contents, Harvard, Yale, Columbia, Chicago, Cornell, and Pennsylvania being among the largest and richest libraries in the country. Many normal schools and colleges give systematic instruction to their students in using books and in the mechanism of the library—not to train them as librarians, but to give them the ability to get the most from books and modern libraries.

Building. The location in cities should be very near the business centre, but preferably on a side street just away from the noise of the main thoroughfare. In larger towns branches and delivery stations of the public library should bring library facilities within easy walking distance of every home. For small public libraries the heavy cost of fireproofing is needless, as most of their books can be readily replaced, and a vault or safe will hold their rarities.

There is no accepted type of library building. For branches in cities and for the libraries of small towns there has been developed a type of structure with reading rooms on either side of the entrance, loan desk opposite the door, and stacks in the rear, which has found common acceptance. Circular, spiral, and other peculiar buildings have won no general approval, except that many recent buildings show a round end with radial stacks in view of the delivery desk.

The best library buildings in America are naturally recent. Of the large libraries, the Newberry Library of Chicago (1893), Boston Public Library (1895), Library of Congress and Chicago Public Library (1897), Providence Public Library (1900), Wisconsin Historical Society and Newark Public Library (1901), District of Columbia Public Library (1902), St. Louis Public Library (1910), New York Public Library (1911), are the most conspicuous for size, cost, and distinctive plans. Among the university libraries the buildings of Columbia, Cornell, New York, Princeton, California, Chicago, and Harvard deserve mention. It is now possible to secure expert advice in planning library structures alike for small and large institutions. State library commissions are always prepared to give this aid, particularly to trustees of small libraries. For large undertakings it is customary to hold a competition to secure a design and an architect. Trustees generally stipulate that they shall be free to use any suggestions in any competitive plan by paying for them, instead of being compelled to choose some one plan as a whole. The consensus of professional opinion may be summed up in the following brief general rules: Plan each library specially for its work and community; care for interiors before exteriors; provide amply for future growth; plan for economy in administration by arranging rooms to allow supervision by the smallest possible staff; sacrifice no convenience for architectural effect. Certain rooms must be near the card catalogue; and the catalogue must be close to reference room, loan desk, and cataloguers. The plan should aim to give direct access to each department without passing through other rooms. The general effect should be cheerful and hospitable. Permanent partitions should be omitted except where necessary for support; and temporary partitions, which can be readily moved as growth and changes demand, are better.

The smallest library occupies one room. As the library grows, its next need is a quiet study room, free from the noise of issue and return of books and current work. The third room needed is usually one for children, which, if possible, should have an independent entrance, so that they will not pass through the doors or corridors used by adults. In more complex structures on the main floor there must be delivery and book rooms for quick service, children's room (unless in the basement), and, if space allows, rooms for librarian, cataloguers, and for reference. Above or below may well go class, trustee, lecture, and other rooms used by fewer people or less often, both rooms and books most used being nearest the entrance. Basement and attic should both be planned so that they can be finished for public use, for the rapid growth of libraries has shown that all available space will surely be needed. The height of book rooms and of the stories of the building should be regulated by that of the book stacks; 7½ feet ordinarily is the unit. In no case should the floors of the stacks fail to register with those of the building. The most common error is in building on too small a lot, as ample space is needed for light and quiet and for inevitable growth.

Book Shelves. The rapid growth of libraries is a constant embarrassment. The most compact possible system of storage is still costly. Small libraries usually house their books on wooden shelves adapted to the dimensions of their rooms. Larger libraries must use a stack, i.e., shelving set close together and yet allowing ready access by aisles. Stacks are of iron or steel uprights with wood or steel shelves, and from 1 to 10 stories or decks high, each deck carrying the weight of all above it, aisles always being exactly over aisles. In computing capacity of shelving, 10 volumes to the running foot are allowed for public libraries, with shelves crowded. Economy requires ample vacant spaces to insert additions, so that shelving must always exceed the calculated capacity. Wall spaces of stack rooms should not be divided into aliquot parts, but into standard shelf lengths. The ordinary standard wooden case is eight shelves (7 feet, 8 inches) high and five tiers (13 feet, 6 inches) long, and uprights 2 inches thick. On its two sides the 10 tiers of 80 shelves hold 2000 volumes in close packing. For a one or two deck stack wood is cheapest. Steel is necessary to carry the load of taller stacks. Where the public has access to the shelves a wide aisle is very desirable. Doors are now never used on library shelves except for rarities. Tall ladders have given way to galleries, 30 to 40 inches wide, as quicker and safer. All books should be within the natural reach of a person 5 feet high. The front edges of shelves and uprights may be rounded to save wear on bindings.

When old buildings are adapted for libraries, extra floor supports must be put under book stacks to carry the great weight. It is wiser, however, to build a wing for a stack with the weight directly on the ground, or on concrete piers.

Reading Rooms. Three types are: (1) the quiet study or reference rooms for research work and study; (2) periodical rooms, which usually suffer from rustling newspapers and noise of constant coming and going; (3) children's rooms. Entrances to periodical and children's rooms should be as near the street as practicable, for convenience and to keep noise away from quiet rooms. Larger libraries need separate reading rooms for art, patents, music, bound newspapers, and other large special collections. Small study rooms are most costly to build and to supervise and so are in little favor. Economy requires for general purposes a large central hall, so that reference books and attendants need not be duplicated.

Special Rooms. Even small libraries need coat and toilet rooms near the entrance. There should be at least one room in which conversation is allowed. The library is a kind of intellectual clubhouse; and those who wish to play chess or other quiet games, discuss books, look at pictures, hold meetings of study clubs or classes, should have a place, as well as the reader demanding quiet. A separate trustees' room is usually wasteful of space, and if built should serve for some use not interfering with the infrequent trustees' meetings. A catalogue and work room is needed for all but small libraries. As work grows, various administrative rooms are demanded.

Light. Good daylight in all parts of the building has become less essential since electricity is so widely used. Windows, preferably on the north or east side, where they avoid direct sunlight, should reach to the ceilings and have square tops, since light area there is worth double that near the floor. In stacks windows exactly opposite centres of aisles are best. Walls should be tinted with colors that reflect instead of absorb light. Bright general illumination with artificial light is usually unnecessary and unsatisfactory in study rooms. A reading lamp on each table, the wire coming from below, is practically essential. Even the best lights on ceilings or distant from tables are injurious to sensitive eyes, if exposed. If general lights are used, they should be so arranged that direct rays do not reach the eye. Proper heat and ventilation are specially important in all portions of a library building.

LIBRARY ADMINISTRATION

The work of the larger public libraries falls naturally into the following departments:

General Administration. The librarian (or director), assistant librarian, secretary, and disbursing officer, with their necessary office forces, are usually met with (under varying names) in libraries of any size. The needs of large city systems call also for some official in charge of the numerous branch libraries. In addition there are the heads of the various departments described below. Most libraries have a classified system for the subordinate service with definite grades and provision for gradual advancement in salary. Seven hours daily is the limit of good work in cataloguing and similar steady, exact work. Eight hours are usually required of attendants whose duties are less exacting. Libraries which have studied results most closely give a full month's vacation with pay, and some allow one additional month during the year for total absence from illness or other causes. Salaries are steadily working upward, with the demand for higher qualifications and fuller professional training. Small rural libraries may be kept open a few hours a week for \$100 to \$300 a year. The great libraries now pay \$5000 or more to their directors. The tendency is to open libraries on holidays, Sunday afternoons, and evenings. Where practicable, hours are generally from 9 A.M. to 10 P.M.

Order Department. This includes the whole work of selecting and getting books and other material, and of handling gifts, the sale or exchange of duplicates, and keeping the accession record. For cataloguing department, see CATALOGUING; for classification, see below.

Reference Department. Systematic aid to readers is given in the smaller libraries by means of an assistant stationed at the information desk or by the reference librarian. In larger libraries the demand has led to adding various assistants who devote their time to answering questions, helping readers to find what they wish, and aiding in the use of bibliographies and catalogues. Larger institutions are developing a library faculty of specialists, each assisting readers in his special field.

The rapid development of reference work is a special feature of recent years in American libraries. The books of the reference librarian are the best reference books, supplemented by card indexes, notes, and all bibliographic devices. The reference department is called on to aid in answering questions on every conceivable subject and aims to teach applicants how to make investigations for themselves and thus in time develop the ability to use to the best advantage a well-equipped library. This department in effect may become the information bureau for its whole constituency. Some investigations, however, require considerable time and are not in their nature of such public value as to be justifiable at public expense. In some libraries these are made for any one willing to pay the pro rata cost of an assistant's time. This gives free use of all library resources and facilities and protects against using the time of public officers for private purposes.

Free access to the shelves is becoming more common, and in most libraries serious students have no difficulty in getting shelf privileges.

Loan Department. This has charge of the registration of borrowers and the issue and return of books. Many libraries allow two or more books (not fiction) to be lent. Books may usually be reserved, and notice is freely sent when books asked for are ready. Interlibrary loans are common, particularly of rare or costly books and manuscripts. A lending library has ceased to be a mere storehouse of books for circulation, but aims to induce its readers to borrow better books by restricting the supply of the less desirable and by inciting interest in the best through annotated lists in newspapers and on slips for free distribution, by illustrated bulletins, by personal suggestions, and by shelves open freely for all to browse among tempting books. Notable gains have resulted from these systematic, intelligent, sympathetic efforts to improve the average of books lent.

Shelf Department. This has entire charge of arrangement and preservation of books and all other material. It must keep all the library collections in order and clean, and find or replace missing books. A complete inventory is taken once a year, but well-managed libraries no longer close for this purpose, but distribute the work of stock taking and cleaning throughout the year. The inventory is taken by means of a shelf list. This has class, book, volume, and accession numbers, author, and brief title of every book, written on loose sheets laced together in a binder, or on cards arranged in the order in which the books stand on the shelves. It forms a brief and very convenient subject catalogue. In the relative system, now almost universally preferred, shelves require no numbers, the class numbers of the books being the sole guide. If shelves are numbered, the plan should be so comprehensive that numbers signify position as well as sequence.

Library Classification. A collection of books must be classified before it deserves the name "library." Classification is putting like things together. Each book, pamphlet, clipping, map, or other item goes with any others like it on a carefully systematized plan, so that matter most closely allied and oftenest used with it will precede or follow closely. Only thus can all reasonable demands of readers be met fully and promptly. The vital importance of classification has long been recognized. Systems of book arrangement have appeared in large numbers, while almost every library formerly followed some scheme of its own, largely governed by local and individual circumstances. It is, however, an almost endless work to prepare a complete scheme, and when done it never wholly suits the maker, much less any one else. To avoid the inevitable delays and confusion of elaborate systems, some libraries were arranged in order of acquisition, some by authors like a directory. Usually there was broad classification by subjects, and librarians and readers did the best they could by aid of bibliographies, subject catalogues, and indexes. Some systems of classification had no indexes. The book number itself in the older American and foreign libraries generally indicated a fixed location on a particular shelf, which had to be altered as often as growth made it necessary to move the books on that subject.

The great desideratum was a system that would do away with the expensive necessity of renumbering books as soon as the growth of the library made it necessary to shift the books. This was provided in 1876 by the publication of the *Decimal Classification and Relative Index*, by Melvil Dewey, which showed by the same number both subject and location. This scheme divides the field of knowledge into nine main classes, numbered 1 to 9. Encyclopædias, periodicals, etc., so general in character as to belong to no one of these classes, are marked 0 and form a tenth class. Each class is similarly separated into nine divisions, general works belonging to no division having zero in place of the division number. Divisions are similarly divided into nine sections, and the process is repeated as often as necessary, the full tables covering some 20,000 topics.

Books on the shelves and cards in the classed catalogue are arranged in simple numerical order, all class numbers being decimal. Since each subject has a definite number, it follows that all books on any subject must stand together under that number. The tables show the order in which subjects follow one another, 512 algebra preceding 513 geometry, and following 511 arithmetic. Of this E. C. Richardson says in his *Classification, Theoretical and Practical* (pp. 199–200), published by Scribners in 1901:

"This system has probably had more vogue than any other bibliographic system ever published save possibly that of Brunet. Taken as a whole and regarding the substantially unchanging form and notation, among the multitude of derived systems with minor variations, it is undoubtedly true that no system ever invented has been applied to as many libraries (probably at the present day several thousand) as this. . . . It is now being adopted very generally on the continent of Europe by booksellers even as well as libraries, and is of late, through its adoption by the Brussels Institute (for international bibliographic work), having a very zealous propaganda by its converts, especially in France and Italy. . . . The reasons for its deserved popularity are to be found: (1) in an intelligent and consistent application of the decimal notation (not new with Dewey, but first by him vigorously and consistently applied); (2) in the grasp of mnemonic possibilities of this situation; (3) in the practical, intelligent, and often up-to-date management of the remoter subdivisions of the, in some places, somewhat artificial, larger subclasses; (4) in the fully printed schedules with their 'relative index,' which more than anything else is the cause of the practicality of this system and its wide adoption. In other words, its popularity has been due to intelligent practical usefulness." The *Decimal Classification* is now adopted by the great majority of public libraries in America and by very many in Great Britain, where, however, it has a serious rival in the *Subject Classification* of J. D. Brown.

The distinguishing features of the decimal classification are:

Relative Index. The card catalogue is rapidly displacing the book form. It could not be indexed like a book by reference to pages, for cards to which additions are made daily could not be numbered like pages. The solution for classed catalogues was to number subjects so that the entry in the relative index was followed by a number which meant not a page of a special book, but a subject in the complete scheme; e.g., geometry in the index is marked 513, meaning Class 5 Natural Science, Division 1 Pure Mathematics, Section 3 Geometry. This relative index number is therefore a key to card catalogue, shelves, pamphlet collections, shelf list, charging system, newspaper clippings, manuscript notes, in fact to everything arranged on the relative system. This feature the decimal classification shares with most modern systems.

Close Classing. All recent experience strongly confirms the wisdom of fairly close classification on shelves, and the practice has so changed that what 30 years ago was called extremely close classification would now be considered medium or even broad. Where libraries depend on catalogues and indexes alone for the resources on any subject, the practice usually results, after a few years, in doing the work over at greatly increased cost. The best results can be obtained only by having as far as physically practicable material on each definite subject standing together.

Simple Notation. In any plan the system of numbers to be placed on the books and cards is of the utmost practical importance. Extreme simplicity is necessary for rapid and accurate use by readers and attendants. Only Arabic numerals and Roman letters are sufficiently simple and familiar to be available for this purpose. Many libraries use nothing but figures to number subjects. The *Expansive Classification* devised and published by C. A. Cutter combines letters and figures, as does the system of the Library of Congress, which is followed by an increasing number of American libraries of the research type. The 26 letters allow 676 combinations with two characters or 17,576 with three, and as compared with Arabic numerals have 18, 46, and 118 times the capacity for three, four, and five characters. This is a great advantage, but produces numbers complicated in appearance. Both expansive and decimal systems, and various other modern schemes of book arrangement, meet the test of a good classification in insuring that books on the same subject shall be classed together and readily found when wanted.

Book Numbers. Mr. Cutter is also author of an ingenious and widely used table to keep books in each class in any system in alphabetical order. The author's initial is followed by a number which is the translation into figures of the rest of the name, so that the system is much simpler in handling and recording than it would be if the author's whole name had to be used. For scientific and other books where chronologic order is preferable, W. S. Biscoe, of New York State Library, devised a translation scheme by which a letter followed by simple Arabic numerals indicates date. Under the subject or class numbers most libraries use Cutter numbers, while many use also Biscoe numbers for science and useful arts.

Mnemonics. Both decimal, subject, and expansive systems make large use of practical mnemonics. These are of much use, especially in geographic divisions, languages, and form distinctions; e.g., since in the decimal classification German is invariably 3 and grammars 5, one knows without reference to tables or index that in class 4 philology German grammars must be 435. Library attendants are greatly aided by these mnemonic features and can often construct a number instantly. The principle also allows very minute subdivisions of topics where it is needed, as in limited divisions of historical periods.

Dictionary Catalogue. The relative index and relative location and closer classification than was thought possible before their invention are now generally accepted. But as arranging a card catalogue by the numbers of the relative index involves the constant use of a printed index or key to subject numbers, and requires a separate card catalogue of authors and titles, most libraries, using the relative location system for classification on the shelves, write specific subject cards and arrange them in the same alphabet with author and title cards in what is called a Dictionary Catalogue. See CATALOGUING.

LIBRARY SCHOOLS AND TRAINING

When near the close of the past century librarianship was very generally recognized as a profession, it was clear that it had the same need for professional schools as law, medicine, or teaching, but nowhere was there offered systematic training for this important field. Young college graduates of unusual promise were ready to enter the new profession, but no adequate facilities for training were offered. Columbia University established the first library school, which was opened Jan. 5, 1887. The three months' course was by petition lengthened to four and then to seven months, and then at once to two years, thus proving a demand for technical training not only larger than estimated, but also for broader and more thorough work than that originally planned. On April 1, 1889, by agreement between Columbia and the State, the school was transferred to the State Library at Albany. Library schools were opened in 1890 by Pratt Institute, Brooklyn, in 1892 by Drexel Institute, Philadelphia, in 1893 by Armour Institute, Chicago, later transferred to the University of Illinois. In 1915 there were 14 schools for training librarians in the United States, six of which require the equivalent of a college degree for entrance. The degree of bachelor of library science is given at three of these schools. Like law and medical schools, a library school offers only a technical course, making no attempt to give general culture. It usually gives only an outline treatment of historical and antiquarian topics, devoting its time to preparing its students for technical service in their chosen field. The course includes bibliography, cataloguing, classification, work of accession, loan and shelf departments, bookbinding, library buildings, administrative, supervisory, and State commission work, selection of books, general library methods and appliances. As practical training is the chief end, seminars, problems, study of libraries in operation, and other features are used in such proportion as experience has shown to give the best results. Practice work in all the different departments under careful supervision is an important factor.

Many large libraries have apprentice classes. Younger staff members and sometimes applicants for positions are organized in a class, assigned a teacher, and trained for several months in order to make them more efficient. Such classes are not open to the public and do not pretend to be library schools; but in a large library systematic class instruction is much cheaper and more effective than individual explanations by older assistants. Many colleges and normal schools give library and bibliographic courses, not to train librarians, but to teach their students how to utilize a large library, how to care for their own private libraries, and to give them a knowledge and interest that will qualify them to serve intelligently as library trustees.

Another form of instruction is for library organizers, members of commissions, or missionary librarians to meet for a day librarians needing assistance and answer questions and make suggestions. The name "institute" has been used for such "round table" work, but should properly be limited to work corresponding closely to ordinary teachers' institutes where most of the week is given to systematic short courses under expert conductors.

Library Associations and Clubs. The first convention of librarians in America was held in New York, Sept. 15–17, 1853, with 53 delegates. The next was held in Philadelphia, Oct. 4–6, 1876, with 103 delegates. At the close the American Library Association, whose object is "to promote the welfare of libraries in America," began its work, which has grown steadily in scope and usefulness. Its annual meetings alternate between East and West, from Boston to San Francisco and from Montreal to New Orleans. Its largest attendance is over 1200. It has sections devoted to special interests, e.g., college, reference, State library, trustees, library commissions, cataloguing, children's libraries, public documents, etc. Its most important branch is the American Library Association Publishing Board, consisting of five members who have charge of preparing and publishing bibliographies and other specially needed library aids. Funds for this board were raised by small subscriptions till in 1902 Andrew Carnegie made a gift of $100,000 for endowment. The board publishes various indexes and other helps to librarians, and certain annotated lists of the best books, for which George Iles has furnished the chief inspiration and most of the funds. The association maintains permanent headquarters with a paid staff in Chicago. Through it the experience of the library profession on many matters is focalized, formulated, and made available to all. At the close of the first international conference of librarians, held in London, Oct. 2–5, 1877, at which 22 Americans were

LIBRARY STATISTICS *

NO.	Library	City	Country or State	No. of vols.
1	Bibliothèque Nationale	Paris	France	4,050,000

present, the Library Association of the United Kingdom, later chartered as the Library Association, began its work. It holds annual meetings at central points in the three kingdoms, and its council holds monthly meetings in London. It gives much more attention to the antiquarian and historical side of library work than the American Association, whose activities have been almost wholly directed to establishing new libraries, improving methods, reducing cost, and other directly practical ends. The National Library Association of Australasia was founded in 1896, in 1900 the Verein Deutscher Bibliothekäre was founded in Germany, and in 1901 the Kansai Bunko Kyōkai or Western Library Association was established in Japan with *Tōheki* as its official organ. In half a dozen other countries, notably Italy, France, and Denmark, growing interest in the modern library movement has been followed by organization. The first State Library Association was organized in New York in 1890, followed rapidly by other States, till now nearly all have such organizations.

In 1885 the New York Library Club, the first local body devoted to library interests, was started. Chicago followed in 1891, and now local clubs are found in most of the large cities and are being established also for groups of counties where the need is felt for more frequent meetings and closer contact than is provided by the State associations.

State Supervision, Grants, and Subsidies. Most of the States have now appointed library commissions, usually of three or five persons serving without salary, but often with a paid secretary or organizer. These commissions have charge of the State's public library interests. The commissions answer questions, help in selecting books, give suggestions and advise as to buildings, methods, and rules, and in several States make grants of books or money to new libraries. New York first of any State or country organized a distinct library department, under the Law of May 1, 1891. It grants for buying approved books as much as is raised from local sources, up to $200 annually. The law also allows grants from local money up to 10 cents for each volume circulated, but only under strict supervision. All books bought with State money must be approved by the Public Libraries Division of the State Library, and the recorded circulation on which subsidies from local funds are granted must be certified as conforming to a proper standard. As yet this plan of subvention by the State has had but few followers in other States. For law libraries in the United States see LEGAL EDUCATION.

LIBRARIUS (Lat., *liber*, book). The ancient Roman name for a copyist or maker of books. See BOOK.

LIBRARY BUILDINGS. See LIBRARIES, *Building*.

LIBRARY OF CONGRESS, THE (the National Library of the United States). A public institution at Washington, D. C. It was established in 1800, destroyed in 1814 by the burning of the Capitol, afterward replenished by the purchase by Congress of the library of ex-President Jefferson, but suffered again by a fire in 1851, which reduced it to 20,000 volumes. It has increased rapidly since then (1) through appropriations by Congress; (2) by deposits under the Copyright Act (see COPYRIGHT); (3) by gifts and exchanges, particularly of public documents; (4) by the exchanges of the Smithsonian Institution, the library of which (40,000 volumes) was, in 1866, deposited in the Library of Congress with the stipulation that future accessions should follow. The collection has now come to be the largest in the Western Hemisphere and one of the half dozen largest in the world. It comprised on June 30, 1914, 2,253,309 printed books and pamphlets, 141,712 maps and charts, 663,474 pieces of music, 376,812 prints, and many manuscripts, including the papers of nine Presidents of the United States. It is rich in history, political and social science, public documents, and in Americana, including important files of American newspapers and original manuscripts (due in part to the acquisition of the Peter Force, the De Rochambeau, and other special collections); but it is now a library general in scope, and its purchases include material in every department of literature. The annual increase of the library amounts to about 125,000 volumes. From 1800 to 1897 it remained at the Capitol; in 1897 it was removed to the building erected for it under acts of Congress, at a cost of $6,347,000, exclusive of the land, which cost $585,000. The building occupies 3¾ acres upon a site 10 acres in extent, at a distance of 1270 feet east of the Capitol, and is the largest and most magnificent library building in the world. It has a floor space of nearly 8 acres; book stacks which contain about 100 miles of shelving and space for 3,540,000 octavo volumes, and 84,000 volumes of newspapers, able to be so extended as to accommodate over 4,000,000 volumes; and provision for nearly 1000 readers at a time. The structure, Italian Renaissance in style, is quadrangular, measuring 470 feet by 340 feet, and incloses four

THE LIBRARY OF CONGRESS
WASHINGTON

courts and a central rotunda. Its numerous works of art are imposing but very unequal in merit. Its organization is now highly elaborate, including besides the general administration various divisions: Order, Catalogue, Reading Rooms, Bibliography, Documents, Manuscripts, Maps, Music, Periodicals, Orientalia, Prints; the Law Library, which still remains at the Capitol; and the Copyright Office; also a branch bindery and printing office which are branches of the Government Printing Office. The total force employed in the library numbers over 500. The Librarian of Congress is appointed by the President of the United States. He appoints his subordinates and otherwise administers the appropriations granted for the Library and Copyright Office. There is also a Superintendent of the Building and Grounds, similarly appointed. Annual appropriations are granted by Congress upon application of these two officials. For the year 1914–15 they amounted to $649,665. The library is open from 9 A.M. to 10 P.M. on every week day, and from 2 P.M. until 10 P.M. on Sundays and most holidays. Established for the use of Congress, and still especially serving Congress, the library is now also a public library, national in scope and function. For reference it is freely accessible without formality; but the privilege of drawing books for home use is at present in general limited to members of Congress and certain other classes of officials. Besides its direct service to readers, equivalent in volume to that of any American library, and to Congress and the executive and scientific bureaus at Washington, the library gives much bibliographic information by mail and through its publications, which, including its annual reports and reference lists, are distributed freely to institutions and serious investigators. It issues no general catalogue in book form. Its printed catalogue cards are, however, placed for reference at certain centres of research outside of Washington, and are supplied at cost to subscribing libraries. It has thus become a central bureau for the cataloguing of all current copyrighted publications and of most others, current and noncurrent, that are of concern to American libraries.

Consult: for history, W. D. Johnston, *History of the Library of Congress* (Washington, 1904); for organization and workings, *Report of Librarian* for 1901 (ib., 1902); for description of the building, H. Small, *Handbook of the Library of Congress* (Boston, 1909); W. W. Bishop, *The Library of Congress* (Washington, 1914).

LIBRARY SCHOOLS. See LIBRARIES.

LIBRA'TION (Lat. *libratio*, a balancing, from *librare*, to poise, from *libra*, balance). A term applied to certain phenomena of the moon's motion. The moon's librations (or, more properly, *apparent* librations) are of three kinds—libration *in longitude*, libration *in latitude*, and the *diurnal* libration. If the moon's rotation in the orbit were uniform, as her rotation on the axis is, we should always see exactly the same portion of her surface; but as this is not the case, there are two small strips of surface, about 7° 45′ in width, running from pole to pole, on the east and west sides, which become alternately visible; this is called the moon's longitudinal libration. The libration in latitude arises from the moon's axis not being perpendicular to her orbit, in consequence of which a portion of her surface round the north pole is visible during one-half, and a corresponding portion round the south pole during the other half of her revolution in her orbit; the libration in latitude is about 6° 41′. The diurnal libration hardly deserves the name, and is really an effect of parallax. It arises simply from the fact that the observer is stationed on the surface of the earth, and not at the centre; it consists in the gradual disappearance of certain points on one edge of the moon's disk as she approaches her culmination, and the appearance of new points on her opposite border as she descends. The combined effect of all three librations is that we can see altogether 59 per cent of the moon's surface; whereas without the librations we should see a trifle less than 50 (49.998) per cent. Only about 41 per cent of the surface is at all times visible from the earth. The first and third of these librations were discovered by Galileo, and the second by Hevelius.

LIBRETTO, lė-brĕt'tō (It., little book). The book or text of any extended vocal composition, notably of an oratorio or opera. As the Italian opera degenerated the libretto became more and more trivial. During the latter half of the eighteenth and the first half of the nineteenth century the text was of so little importance that the same libretto would be retouched or slightly altered and set to music by many different composers. Serious composers always had difficulty with librettists. Beethoven for a long time wished to write operas, but after his experience with *Fidelio* abandoned dramatic composition forever, because he could not find a suitable text. Wagner began his reforms by insisting upon a good text. But, being a poet himself, he was not dependent upon others. The texts of his earlier works (to *Lohengrin* inclusive) are libretti in the true sense, being divided into arias, choruses, duets, quartets, etc. But they possess literary merit because of the logical and artistic development of the plot and the beauty and force of the language. It would be wrong to apply the term "libretto" to the text of Wagner's later works. They are dramas in the true sense of the word. The influence exerted by Wagner upon librettists has been so strong that since his time a poor or ineffective libretto is the exception. Consult Edgar Istel, *Das Libretto* (Berlin, 1914), and United States Library of Congress, Division of Music, *Catalogue of Opera Librettos Printed before 1800* (Washington, 1914).

LIBREVILLE, lē'br'-vēl'. The capital of the Gabun Colony, French Equatorial Africa, situated on the coast at the estuary of the Gabun (Map: Congo, A 2). It is an important seaport and coaling station. The population in 1911 was 1573 natives and 175 Europeans.

LIBRI CAROLINI. See CAROLINE BOOKS.

LIBRI-CARRUCCI, lē'brė-kȧ-rōō'chė, GUGLIELMO, COUNT (1803–69). A French mathematician. He was born at Florence and was educated at Pisa, where he was professor of mathematics and physics until 1830, when he went to Paris as a political refugee. He was naturalized in 1833; became professor of analysis at the Sorbonne; and succeeded Legendre in the Academy of Sciences. He was promoted to be inspector general of the University and of the public libraries of Paris. He was also an editor of the *Journal des Savants*. In 1847 he was accused of stealing valuable books and manuscripts under his charge; in 1850, after his escape to England, he was found guilty and was sentenced to 10 years' imprisonment. Among his really important works in mathematics and physics are contributions to Crelle's *Journal* (1835) and the *Histoire des sciences mathématiques* (1838–41 and 1865).

LIBRO D'ORO, lē'brō dō'rō (It., Golden Book). A book in which was inscribed, originally in letters of gold, a roll of all members of the nobility of Venice. All persons 25 years of age whose names were there registered were members of the Grand Council. The Golden Book of Venice was burned by Napoleon in 1797. Similar registers were kept in other Italian republics, and the term came to mean in general any list of honors.

LIBUR'NÆ NA'VES. See LIBURNIA.

LIBUR'NIA (Lat., from Gk. Λιβουρνία, *Libournia*). In ancient geography, a mountainous district of Illyricum on the Adriatic coast, and the adjacent islands, now a part of Croatia and Dalmatia. From early times the Liburni were daring seamen, and were in the possession of Corcyra, Issa, and other islands when the Greeks occupied these places. They were noted pirates, and their privateers, with large lateen sails, were for centuries the terror of the seas. Later Liburnia was included in the Roman Province of Dalmatia, and the Liburni served in the Roman navy. The galleys of the Liburni were noted for their light construction and swiftness, and the Romans, adopting this style of naval architecture, called all fast-sailing vessels *naves Liburnæ*. By means of these light galleys Augustus gained the battle of Actium. The only important towns in Liburnia were Iader and Scardona. For authorities consult the article "Liburni" in Friedrich Lübker, *Reallexikon des klassischen Altertums*, vol. ii (8th ed., Leipzig, 1914).

LIBUR'NUM. See LEGHORN.

LIBUSSA, lē'bụ-shȧ. An opera by Smetana (q.v.), first produced in Prague, June 11, 1881.

LIBYA, lĭb'ĭ-ȧ (Lat., from Gk. Λιβύη, *Libyē*). The name given by the oldest geographers to the whole continent of Africa. In the Roman period the name Africa was generally used for the continent as a whole, while the name Libya was applied specifically to what is now known as the Libyan Desert (q.v.), together with the strip of land just north thereof, lying along the coast, and corresponding in part to Tripoli. See AFRICA.

LIBYAN, lĭb'ĭ-an (*Luba*, *Levata*, Egypt. *Lebu*, Gk. Λίβυες, *Libyes*). A branch of the Hamitic stock, or linguistic family, occupying from most ancient times the north of Africa between the Barcan Desert and the Atlantic Ocean. They include in Morocco *Amazirg* (Berbers), *Rifians*, and *Shelhas* (Shluhs); in Senegal, *Senagas;* in the Desert, *Tuaregs* and *Tibbus;* in Algeria, *Kabyles*, *Shawia*, and *Beni-Mzab* (Mzabites); in Tripolitana *Zouaves* and *Jelel*, and *Ghadames*, southward.

The Libyan people are of medium stature (5 feet, 7 inches) and in build are spare, but strong. They are fair-skinned, and much lighter than the average fellah of the Nile or than the Arabs. Dark hair and hazel eyes are more frequent than light hair and blue eyes, though in all villages persons resembling the North German type are to be seen. It is interesting to note how this mark has persisted. On the walls of the tomb of Seti I and Merenptah (1300 B.C.), at Thebes, are shown four types, representing the Egyptian, the Asiatic, the Negro, and the Libyan. The Egyptians are painted red, but the Libyans are white, with blue eyes and fair beards, preserved until this day in the blond Berber, from Tripoli to Tangier and far into the desert.

The home of the Libyans is for the most part a mountainous region, here and there lifted above the snow line and flanked by a piedmont on north and south, the former sloping into the Mediterranean, the latter towards the Sahara.

As distinguished from the nomadic and predatory Arabs, the Libyans are and have been partly agricultural, partly industrial, and partly commercial. The difficult traffic across the Sahara into the Negro Sudan has been theirs from time immemorial. For the prosecution of this commerce horses, camels, and asses were needed, and the rearing of these gave variety to their activities. Agriculture has always been their congenial pursuit. In the narrow valleys terraced gardens are common, but in the wider, more open spaces the plow takes the place of the hoe and the implements seem not to have changed their form in many hundreds of years. The Libyans possess little mechanical skill, as is evidenced by their mills, looms, and metallurgy. Pottery is made by hand, without the wheel, by modeling or building up by coils, and burnt in little kilns in the open air. In some tribes, the Kabyles (q.v.), e.g., the forms and decorations remind the student of the most ancient ceramics of Egypt.

The dress of the Libyans of to-day is for the men a cotton or woolen undergarment and over this a burnoose, consisting of blankets sewed together and having a capuchin hood attached. Sandals with soles of plaited grass complete the costume. To this a caida (*Kaid*) will add a scarf, loose tunic, sleeved waistcoat, embroidered waistcoat, a girdle, and a turban, besides a rosary, boots or stockings of red leather, and large black shoes.

The women wear a single tunic of coarse material, with holes for the arms, tied up at the waist with a girdle. A profusion of silver ornaments is common, and finer garments with gay headdress are worn on festive occasions.

The unit of Libyan social life is the monogamous family; in which the women do not go veiled, but custom lays on them many restrictions. The unit of political life is the village community, with purely democratic government, unless outside influences have prevented, as among the Tuaregs. The presiding officer of the general assembly has no power of initiative, but is the servant of the village. Villages are united into tribes, for geographic and economic reasons, and these in great emergencies unite in confederacies. Beneath this democratic system and modifying its action exist secret societies or organizations which are sworn to protect their members in every difficulty. Excepting on the rarest occasions the Libyans have never developed a national spirit.

The Libyans or Berbers have been Mohammedans since the seventh century. Herodotus says that the Libyan nomads sacrificed to the sun. Egyptian, Greek, and Roman polytheisms, singularly enough, make little impression on them. Beyond nature worship and the wearing of charms they were almost without a cult. Consult: Randall-MacIver and Wilkin, *Libyan Notes* (London, 1901); Arnold van Gennep, "Etudes d'ethnographie algérienne," in *Revue d'Ethnographie* (Paris, 1911); Franz Stuhlmann, *Ein kulturgeschichtlicher Ausflug in den Aures* (Hamburg, 1912); Bertholon and Chantre, *Re-*

cherches anthropologiques dans la Berbérie orientale (Lyons, 1913). See BERBER, and the various Libyan tribes under their special designations.

LIB′YAN DESERT (Lat. *Libyæ deserta*). That part of the African continent lying between Egypt and Fezzan and extending from the Mediterranean to Darfur. It contains a number of oases, or fertile tracts, islands of verdure in the vast sands, which support a sparse population; but the surface generally consists of irreclaimable sandy or gravelly plains, separated by low rocky ridges, or shelving down in a series of terraces towards the Mediterranean. Consult J. C. S. Falls, *Drei Jahre in der libyschen Wüste* (Freiburg, 1911; Eng. trans. by E. Lee, London, 1913), and F. G. Alexander, *Wayfarers in the Libyan Desert* (New York, 1912). See LIBYA.

LIBYAN LANGUAGE. See AFRICAN LANGUAGES.

LIBYAN SEA (Lat. *Mare Libycum*). The name given in ancient geography to that part of the Mediterranean which lies between the island of Crete and the coast of Africa.

LICATA, lē-kä′tȧ, or **ALICATA**, ä′lē-kä′tȧ. The most important city commercially on the south coast of Sicily, at the mouth of the Salso, in the Province of Girgenti, 137 miles by rail southeast of Palermo (Map: Italy, D 6). It is beautifully situated on the lower slopes of the hill of Sant' Angelo, known as Ecnomus to the ancients. It has a Gothic church and a technical school. The principal export is sulphur. The country produces grain, wine, olives, fruit, cheese, wool, hides, and cotton, and the sea yields anchovies and sardines. Here in 256 B.C. Regulus (q.v.) vanquished the Carthaginians in the naval battle of Ecnomus, and in 249 Carthalo, favored by a storm, destroyed a fleet of Roman transports. Pop. (commune), 1901, 22,031; 1911, 24,530.

LI′CENSE (OF., Fr. *licence*, It. *licenza*, from Lat. *licentia*, license, from *licere*, to be permitted). In music, the liberty which a composer takes in deviating from the rules of his art, and which is often marked with the words *con licenza* in order to indicate that it has been introduced intentionally to produce some unusual effect. Many licenses occur, however, in the works of great composers like Mendelssohn, Bach, and Haydn, where the notice *con licenza* is omitted, but it will generally be found that they are introduced for the purpose of characterization. Especially in dramatic music much license is permitted in order to obtain characteristic expression, such as leading voices in open fifths or doubling intervals that ought not to be doubled according to the rules of strict writing.

LICENSE. In general, an authority given by one person to another to do an act which but for such authority would be an infringement of the licensor's rights or a violation of a prohibitive statute or regulation. Specifically the term includes licenses by a landowner to enter upon or otherwise use his land, usually for a temporary purpose, and licenses by municipal or other public authority to ply certain trades or callings.

Licenses of the former sort cover a wide range of permissive use of the licensor's property. They may or may not be based on a consideration, but in neither case do they confer on the licensee any right or interest entitling him to assert the privilege or authority conferred by the license, but are revocable at the will of the licensor and are revoked *ipso facto* by his death or alienation of the property. Of this kind are licenses to fish or hunt or cut wood on the licensor's property, to witness a theatrical performance or athletic game or other sporting event, to enter and dine in a restaurant, and the like. As has been said, the privilege confers no right on the licensee to remain in the place which he has been licensed to enter nor to continue the use thereof after the license has been revoked. If the licensee has paid for the privilege, as for a theatre ticket, his only remedy is in contract for the damages sustained by him through the breach. The only qualification of this rule is in the case when a license is "coupled with an interest," or property right, in the premises, as where a tenant in an apartment house has a license to use the stairs or elevator to reach his apartment. In such case the license is irrevocable so long as the interest continues.

Licenses are classified as *executory*, when not yet acted upon, and *executed*, when acted upon. It is sometimes said that "a license executed is not countermandable," but this is generally true only in the sense that the revocation of a license does not have a retroactive effect so as to convert into a trespass an act which was performed while the license to perform it was still in effect. In two cases, however, the doctrine that an executed license is not revocable is literally applied, viz., where one having an easement in another's land licenses the servient tenant to erect a wall or other structure on his own land which has the effect of preventing the further use of the easement, and where a person licenses his neighbor to erect on his own land a dam or other structure which interferes with the licensor's enjoyment of his land, as, e.g., by backing up water upon it. In neither case can the licensor recall the authority he has given and require the licensee to undo what he was licensed to do or hold him liable for the damage resulting therefrom. In one or two of the United States it has been held that a person who has paid for a seat in a theatre and taken possession, or who has at great expense erected a dam or mill in pursuance of a license so to do, is protected against a revocation, but such cases are exceptional. It is generally held, however, that where a license is based upon a consideration and where it purports to confer upon the licensee a permanent right to use the licensor's land in a specific way, as to dam back the water of a stream upon it or to convey water by a pipe through it, the courts of equity will restrain the licensor by injunction from interfering with the executed arrangement, on the principle of the specific performance of contract. See EASEMENT; REAL PROPERTY, and authorities there referred to.

The most common licenses of the second sort are licenses to sell liquor, to exercise the trade or calling of a peddler, to give theatrical or other public entertainments, to hold public meetings, to use the streets for processions, etc. Such acts are in themselves innocuous and do not constitute a violation of the common law, but are generally restricted by statute or by local municipal ordinances in the interest of public order and safety. Such licenses are a matter of statutory regulation, and, as they are usually granted only on payment of an annual fee, they are frequently resorted to by the state or by a municipal corporation as a revenue measure. A heavy license fee is sometimes imposed for the purpose of discouraging or restricting a calling which is deemed by public authority to be obnoxious to the interest or welfare of the community. This is the method which has commonly been employed in the United States, as an alternative to the policy of prohibition, for regulating the traffic in, and for diminishing the use of, intoxicating liquors. See INTOXICATING LIQUORS; LIQUOR TRAFFIC.

The term "license" is used in international law for the authority given by a state engaged in war to its subjects or the subjects of the state with which it is at war, to engage in a trade forbidden in time of war. The right to give such licenses is original with the sovereign power, and they may be given by commanding officers in the army or navy as its delegates.

A license in patent law is a permission to make or sell a patented article. To be legally effective, it is required by act of Congress to be duly executed in writing and to be filed in the United States Patent Office at Washington. See PATENT.

LICEN′TIATE (ML. *licentiatus*, p.p. of *licentiare*, to license, from Lat. *licentia*, license). A university degree between that of bachelor and doctor or one holding that degree. It is used somewhat in Europe to indicate a person who has taken certain examinations and is licensed to lecture.

LICHAS, lī′k*a*s (Neo-Lat., from Gk. λιχάς, space between the thumb and forefinger). An interesting genus of fossil trilobites found in rocks of Ordovician and Silurian age. The genus is characterized by broad flat carapaces, short wide head, small eyes, and peculiar lobation of the central portion of the head shield. The genus has several allies, especially in the Devonian, that have the most extravagant spinose ornamentation. One of the simpler forms, *Lichas bigsbyi*, is a well-known characteristic index fossil of the Niagara group. See TRILOBITA.

LICHEN, lī′kĕn (Lat. *lichen*, from Gk. λειχήν, *leichēn*, λιχήν, *lichēn*, tree moss, ringworm; possibly connected with λείχειν, *leichein*, Skt. *rih*, *lih*, OChurch Slav. *lizati*, Lat. *lingere*, to lick, OIr. *ligim*, I lick, OHG. *leokōn*, Ger. *lecken*, AS. *liccian*, Eng. *lick*). A dry, papular disease of the skin. Formerly there existed considerable confusion in the use of the term; but since the time of Hebra, the Vienna master, it has been limited to (1) *lichen scrofulosum* and (2) *lichen ruber*. The former has now been definitely classed among the cutaneous tuberculoses, leaving *lichen ruber* as the only affection regarded by dermatologists as entitled to the name. In most cases, especially in neurotic subjects, there is much itching, which provokes destructive scratching. The disease is an affection of nervous origin, following sorrow or violent nervous emotions, and is often accompanied by insomnia, agitation, and headache. Hot sedative douches, arsenic, and proper diet and hygiene produce good results, aided by external application of carbolic acid, pilocarpine, mercury, lead, chrysarobin, and the curette. Consult H. W. Stelwagon, *Essentials of Diseases of the Skin* (7th ed., Philadelphia, 1909).

LICHENIN, lī′kĕn-ĭn. A gum found in Iceland moss, from which it is extracted by digesting the moss in a cold, weak solution of carbonate of soda for some time and then boiling. By this process the lichenin is dissolved and on cooling separates as a colorless jelly. Iodine imparts no color to it. Glacial acetic acts upon it, yielding a tri-acetyl derivative. Lichenin is accompanied in Iceland moss by another gum, known as *iso-lichenin*, which, unlike lichenin, is colored blue by iodine and does not react with glacial acetic acid.

LICHENS, lī′kĕnz (Lat. *lichen*, from Gk. λειχήν, *leichēn*, λιχήν, *lichēn*, lichen). A very large group of plants, forming splotches of various colors on tree trunks, rocks, old boards, etc., and also growing upon the ground and hanging in clusters from the crowns of trees. They may resemble incrustations on these various supports; or they may form very definite flat and lobed bodies that are not attached throughout to their supports; or they may form slender branching bodies that are erect, hanging, or prostrate. The so-called reindeer moss is an erect branching lichen, common in north latitudes; and in certain mountain regions trees are frequently thickly covered with the hanging lichens. Lichens seem to require pure air and are scarce in the neighborhood of cities. The most important fact about a lichen is that it is made up of two very different plants, a fungus and an alga; but these two are so closely associated that they seem to belong to a single body. In fact, a lichen is a parasitic fungus that obtains its food supply from certain algæ and in doing so enwraps the alga completely. Apparently the algæ are not injured, and in fact their position in the midst of a moist, spongelike body is very favorable for their work. This means that in this position the algæ manufacture food enough for themselves and for the fungus, for otherwise they would be destroyed. This association, known as symbiosis, has led to some very important results. It makes it possible for the two plants to exist in conditions that would be impossible for either plant alone. For example, lichens are abundant on bare rocks from which all other plants are absent. In ascending mountains, after all other vegetation has disappeared, the lichens persist on the most exposed rocks. In such places the alga could not grow alone because of lack of moisture, and the fungus could not grow alone because of lack of food; but in the spongelike body of the fungus the alga gets its moisture, and from the enmeshed alga the fungus gets its food. This fact is important because lichens can thus start soil formation on bare and exposed surfaces. The materials of their dead bodies give to other plants a chance to grow, and so a soil gradually accumulates. With few exceptions lichens are Ascomycetes (q.v.), parasitic upon algæ belonging for the most part to the Cyanophyceæ (q.v.) and Protococcales. (See CHLOROPHYCEÆ.) The dual nature of lichens was announced by Schwendener in 1868, but it was many years before the proof of it became convincing. In 1889 Bonnier began to synthesize lichens, that is, to bring together "wild algæ" and lichen fungi, and thus produce artificial lichens. The lichen fungus usually forms a thallus body, much more definite and differentiated than other mycelia (see FUNGI), the thallus often resembling in form that of certain liverworts. In structure there is a distinct, compact cortical region and a central looser region, in either of which the algæ may occur. On the basis of habit, three types are recognized: (1) crustose lichens, with an undefined mycelium, often penetrating the substratum; (2) foliose lichens, with a definite liverwort-like thallus, which has marginal growth and rhizoids; and (3) fruticose lichens, which are erect and often branching, or pendent and branching. Vegetative mul-

tiplication is secured by soredia, which are scalelike or globular bodies composed of a little tangle of mycelium with some algal cells. The ascocarps are very conspicuous structures, usually being disklike forms.

LICH'FIELD. An ancient city in Staffordshire, England, a civic county, 15 miles southeast of Stafford (Map: England, E 4). Considerable brewing is carried on, together with market gardening and manufacturing of harness, carriages, and carpets. Its chief edifice is the cathedral, a red sandstone building of fine proportions in the early English style, dating from the thirteenth and fourteenth centuries and occupying a commanding site. Its length is 403 feet; width of transepts, 149 feet; of nave, 65 feet; and height, 60 feet. It is surmounted by three spires, the central spire being 260 feet high, and the two western spires each 190 feet high. Other notable features are the western façade, ornamented with one hundred statues in niches; the triforium, the Lady Chapel, and several fine monuments. The cathedral, formerly surrounded by a wall, was besieged and damaged greatly by the Puritans in 1643. It was restored by Wren, who built the central spire; at the end of the nineteenth century it again underwent a complete restoration. Adjacent to the cathedral is the close containing the picturesque episcopal palace on the north side, with a flourishing theological college on the south. The city also contains a museum and public library, a probate court, and the ancient hospital of St. John. Lichfield has a free grammar school, in which Addison, Ashmole, Johnson, and Garrick, natives of the town or vicinity, were educated. The market place contains a colossal statue of Dr. Johnson, whose birthplace is preserved and contains many relics of the great lexicographer. Lichfield was made an episcopal see in 669, and received its city charter in 1549. Pop., 1901, 7900; 1911, 8616. Consult John Britton, *History and Antiquities of the See and Cathedral of Lichfield* (London, 1836); W. Beresford, *Lichfield* (ib., 1883); A. B. Clifton, *Cathedral Church of Lichfield*, in "Bell's Cathedral Series" (ib., 1898).

LICH GATE (from *lich*, AS. *līc*, OHG. *līh*, Ger. *Leiche*, Goth. *leik*, corpse, body + *gate*), or CORPSE GATE. A churchyard gate with a porch or shed attached. Such gates are common in many parts of England. The bodies of persons brought for burial are set down under the shelter of the roof while the service is read.

LICHI NUT. See LITCHI.

LICHTENBERG, lĭk'ten-bĕrk. A residential suburb of Berlin, on the east, practically a part of the capital (Map: Germany, J 5). It was united with Rummelsburg-Boxhagen in 1912. It contains many philanthropic institutions of Berlin and manufactures ironware, pharmaceutical implements, railway signals, stoves and heaters, pianos, leather goods, carpets, and dyes. Pop., 1900, 43,372; 1910, 81,199.

LICHTENBERG, GEORG CHRISTOPH (1742–99). A German physicist and satirist, born at Oberramstadt, Grand Duchy of Hesse. He received his first instruction in mathematics and physical studies from his father, and after studying at Göttingen was appointed professor in the University of Göttingen in 1769. At the end of that year he went to England, where he mingled and studied with many of the leading scientists of his day. The results of his investigations appeared later in numerous discoveries in the field of electricity, of which the most important were the electrical figures named after him. In England he became a frequent visitor to, and student of, the theatre in which Garrick was then a distinguished figure. Moreover, a keen observer by nature and training, in his study of English literature he was soon impressed by the inferiority of the German wit to that of such men as Swift, after whom he later patterned to some extent his own satiric method. After a second visit to England (1774–75), he resumed his lectures on experimental physics at Göttingen. He continued, however, to devote much time to literary pursuits. His keenness of wit and his boundless resources of ridicule resulted in his publication of several well-aimed satires, of which the best known are his *Ueber Physiognomik wider die Physiognomen*, against the new science of physiognomy of Lavater (q.v.), and his *Ueber die Pronunciation der Schöpse des alten Griechenland*, against Voss. From 1778 he edited the *Göttingscher Taschenkalender*, in which he severely attacked the Storm and Stress writers. Here he published in part his articles on Hogarth, whom he did much to popularize in Germany. In the completed work, the *Erklärung der hogarthischen Kupferstiche* (1794 et seq.), he gave the most brilliant proof of his critical power by his clear explanation and interpretation of the English artist's work. In later years he was affected by hypochondria, but, though forced to withdraw from society, continued his studies and writings. His *Gedenkbücher*, or Diaries, contain interesting maxims, epigrams, and brief essays. Consult Franz Lauchert, *Lichtenbergs schriftstellerische Thätigkeit* (Göttingen, 1893); E. Ebstein, *Aus L's Korrespondenz* (Stuttgart, 1906); Alex. von Gleichen-Russwurm, *Zur Einführung in G. C. Lichtenberg* (Jena, 1907).

LICHTENBERG, LEOPOLD (1861–). An American violinist, born in San Francisco. He first appeared in public at the age of eight. Four years later he came under the tuition of Wieniawski and toured with him through the United States. Subsequently he was for six months under Lambert in Paris, rejoined Wieniawski in Brussels, and, devoting himself for three years to serious study, was enabled to win a first prize at the national "concours." He returned to America; in 1877 was soloist for the Theodore Thomas concerts; made a three years' tour of Europe; then became a member of the Boston Symphony Orchestra; and was appointed head of the violin faculty of the National Conservatory of Music, New York. Together with Adèle Margulies (piano) and Leo Schulz (cello) he formed the Margulies Trio, which soon ranked with the foremost chamber-music organizations of the United States.

LICHTENBERGER, lĭk'ten-bĕr-gĕr, FRÉDÉRIC AUGUSTE (1832–99). A French theologian, born at Strassburg. He obtained his degree in theology and was made professor at the university of his native town (1864). In 1877 he was appointed professor in the newly founded Protestant faculty at Paris, of which he also became dean. His publications include: *La théologie de Lessing* (1854); *De Apostolorum Præceptis Redemptoriam Christi Mortem Spectantibus* (1857); *Etude sur le principe du protestantisme* (1857); *Des éléments constitutifs de la science dogmatique* (1869); *Histoire des idées religieuses en Allemagne depuis le milieu du XVIIIème siècle* (1873; 2d ed., 1887).

LICHTENSTEIN, lĭκ′ten-stīn, Martin Heinrich Karl (1780–1857). A German traveler and zoölogist. He was born at Hamburg and studied medicine at Jena and Helmstedt. He went as physician and tutor with the Dutch General Janssens to South Africa (1801) and served as surgeon to an infantry battalion of Hottentots and as governmental commissioner to the Bechuanas (1805). In 1806, on the occupation of the colony by the English, he returned to Germany, devoting himself to the study and classification of the zoölogical and especially ornithological material he had collected in Africa. In 1811 he was made professor of zoölogy at Berlin, and two years afterward was appointed to succeed Illiger as director of the Zoölogical Museum, which under his supervision became one of the greatest on the Continent. His more important publications were *Reisen im südlichen Afrika* (1810–11) and *Darstellungen neuer oder wenig bekannter Säugetiere* (1827–34).

LICHTENSTEIN, Ulrich von. See Ulrich von Lichtenstein.

LICHTWER, lĭκt′vĕr, Magnus Gottfried (1719–83). A German fabulist. He was born at Wurzen, studied law at Leipzig and Wittenberg, and was subsequently canon of St. Mauritius. His chief work is to be found in the *Vier Bücher aesopischer Fabeln* (1748). Some of these are still popular. There is a collection of *Schriften* (1828) edited by von Pott and Cramer. Consult J. Minor, *Fabeldichter, Satiriker des 18. Jahrhunderts* (Stuttgart, 1884).

LICIN′IAN ROGA′TIONS (Lat. *rogationes Liciniæ*, from *rogare*, to ask; used of the magistrate who asked the people whether it approved a proposed law). A rogation was the term for a bill proposed by a Roman magistrate for incorporation in the laws of the state. In 367 B.C., after a struggle of almost 10 years, the tribunes Licinius Stolo and Lucius Sextius secured the adoption of a law that put an end to the long strife between the patricians and the plebeians. It provided (1) that the office of consular tribune should be abolished, and that one of the two consuls should be a plebeian; (2) that no one should hold more than 500 *iugera* (about 250 acres) of the public land; (3) that no one should pasture more than 100 cattle or 500 sheep or goats upon the public lands; and (4) the easy payment of accumulated debts. The first plebeian consul under the new law was Lucius Sextius himself. Consult G. W. Botsford, *The Roman Assemblies*, Index, s.v. "Leges Licinia Sextia" (New York, 1909), and the authorities cited under "Lex, 52," in Friedrich Lübker, *Reallexikon des klassischen Altertums* (8th ed., Munich, 1914). See Agrarian Laws.

LICIN′IA′NUS, Granius. A Roman historian. See Granius Licinianus.

LICINIO, lē-chē′nē-ō, Bernardino. A Venetian painter of the Renaissance. (Active 1520–44.) The dates of his birth and death are unknown, but he was born at Pordenone, and was a pupil of his relative, the great Pordenone (q.v.). Later he was influenced by Giorgione, Palma, and Bonifazio. He was one of the first to paint family portrait groups. Several of these survive, all representing an artist surrounded by his family and pupils, of which good examples are in the Borghese Gallery, Rome, at Hampton Court, and at Alnwick Castle. He is better known, however, for his single portraits, including those of Ottaviano Grimani, in the Vienna Gallery; "A Young Man," in the National Gallery, London; "A Lady Seated," in the Dresden Gallery. He also painted religious pieces, of which a "Madonna Enthroned," in the church of the Frari, Venice, is a real masterpiece, brilliant in color and filled with vitality, though not elevated in conception.

LICIN′IUS, Gaius Flavius Valerius (c.270–324). A Roman emperor. A Dacian or Illyrian by birth, he entered the Roman army and rose to high command. The Emperor Galerius (q.v.), a comrade in old campaigns, made him Augustus (307), after the death of Flavius Valerius Severus, with control of Pannonia and the Alpine district. Galerius died in 311, and Licinius strengthened himself in the West by marrying the half sister of Constantine and by concurring in the Western Emperor's edict of toleration of the Christians. By his defeat of Maximinus (q.v.) at Adrianople, Licinius became sole Eastern Emperor. But he soon quarreled with Constantine. He was defeated near Cibalæ in Pannonia (314) and gave up to Constantine his European domain, except Thrace and a part of Mœsia. Having taken up arms again and been defeated a second time by Constantine at Adrianople and Chrysopolis, near Chalcedon in Bithynia (323), he surrendered and was executed for treason, in spite of promises that his life would be spared. Consult *Cambridge Mediæval History*, vol. i (New York, 1911).

LICINIUS CRASSUS. See Crassus.

LICINIUS MACER CALVUS, Gaius. See Calvus, Gaius Licinius Macer.

LICIN′IUS STO′LO, Gaius. A Roman statesman, tribune of the people in 377 B.C., consul in 361. He was one of the authors of the Licinian Rogations (q.v.). Tradition said that he was himself fined for using a larger amount of the public lands than was allowed by the Licinian Rogations.

LICK, James (1796–1876). An American philanthropist, born at Fredericksburg, Pa. He was early a pianoforte manufacturer in Philadelphia, Buenos Aires, Valparaiso, and elsewhere. In 1847 he settled in California, where he invested in real estate and made a fortune. In 1874 he placed $3,000,000 in the hands of seven trustees, to be devoted to certain specified public and charitable uses. He twice appointed a new board of trustees. Lick's principal bequests were: to the University of California for the erection of an observatory, and procuring therefor a telescope superior to and more powerful than any before constructed, $700,000; to found an old ladies' home in San Francisco, $100,000; for the erection and maintenance in San Francisco of free public baths, $150,000; for the erection of three groups of bronze statuary, representing three periods in the history of California, to be placed before the city hall of San Francisco, $100,000; to erect in Golden Gate Park a bronze monument to Francis Scott Key, $60,000; to found and endow the California

School of Mechanic Arts in San Francisco, $540,000. See LICK OBSERVATORY.

LICK′ING RIVER. A river of Kentucky. It rises in the southeast corner of the State (its headwaters originating about 20 miles west of the Cumberland Mountains), flows in a generally northwesterly direction (its total length being about 350 miles), and empties into the Ohio opposite Cincinnati (Map: Kentucky, G 3). At high water small steamboats can ascend to Falmouth, a distance of 60 miles.

LICK OBSERVATORY. An astronomical observatory situated on Mount Hamilton, an eminence in the Coast Range, California, 4209 feet high, and about 13 miles east of San Jose. It is reached by a carriage road 25 miles long but of easy ascent. The observatory, which was completed in 1888, constitutes the astronomical department of the University of California. The advantages gained by this particular situation are an unobstructed view for a radius of 100 miles, and opportunity for observation during the greater part of the year, clear nights occurring regularly for six or seven months. The great telescope is the second largest refracting telescope in the world, the objective having a clear aperture of 36 inches, and is surpassed only by the 40-inch telescope at the Yerkes Observatory (q.v.) near Chicago. It has a focal length of 57 feet, 10 inches, and the cast-iron column on which it rests has a dimension at the base of 17 feet north and south and of 10 feet east and west. The point of suspension of the telescope tube is 36 feet from the floor. The dome, which has an exterior diameter of 76 feet, is moved by water power, as is the observation platform. A smaller dome contains a 12-inch telescope. In front is a piazza, and on the back a plain of about 100 yards in extent has been made by blasting off a peak of the mountain. Upon this a meridian circle is mounted; also a transit instrument and a photoheliograph. On a slightly lower hill, 1200 feet to the south, is a 3-foot reflecting telescope, that formerly belonged to Crossley of England. A lens for photography has been so arranged that it can be attached to the end of the big telescope. The entire fund for the construction of this observatory was given by James Lick. See LICK, JAMES.

LIC′ORICE, or **LIQ′UORICE** (OF. *licorice*, from Lat. *liquiritia*, corrupted from *glycyrrhiza*, Gk. *γλυκύρριζα*, *glykyrrhiza*, licorice plant, from *γλυκύς*, *glykys*, sweet, + *ῥίζα*, *rhiza*, root), *Glycyrrhiza*. A genus of perennial herbs of the family Leguminosæ, the members of which have long, pliant, sweet roots and generally creeping rootstocks; odd-pinnate leaves of many leaflets; flowers in spikes, racemes, or heads. The roots are valuable because of a yellow transparent, uncrystallizable substance called glycyrrhizin, allied to sugar, soluble in both water and alcohol, and used in medicine, being a constituent of many cough mixtures. The common licorice (*Glycyrrhiza glabra*), native of the south of Europe and of many parts of Asia, has stems three to four feet high and racemes of whitish violet-colored flowers. It is cultivated in many parts of Europe, chiefly in Spain and Russia. It has been grown to a limited extent in Louisiana and California. The roots are extensively employed by porter brewers. They are imported into the United States in considerable quantity, and the black concentrated extract of them (black sugar or stick licorice) is largely imported from the south of Europe, in rolls or sticks, packed in bay leaves. After a plantation has been made, almost three years must elapse before the roots can be dug for use. Licorice requires a deep, rich, loose soil, well manured. The roots penetrate to the depth of more than a yard; straight taproots are most esteemed. The plant is propagated by cuttings of the rootstocks, but when once planted the ground will be stocked for many years because the small pieces of root left after digging will grow. The plant is likely to prove a pest upon land suitable to its growth. The roots of the prickly licorice (*Glycyrrhiza echinata*) are used in the same way, chiefly in Italy and Sicily, Russia, and the East. *Glycyrrhiza lepidota*, an indigenous species, is found from Minnesota to Wisconsin, New Mexico and westward, and sometimes sporadically in the East.

LICORICE.

LIC′TOR. The official attendant of a magistrate in ancient Rome. The origin of the name is obscure; ancient writers derive it from *ligare*, 'to bind,' because it was the lictor's duty to bind criminals for execution, or because he bound them figuratively in the punishment of their wrongdoing; to this view it has been objected that the proper form of the word, if it is derived from *ligare*, would be *ligator*. Many modern scholars connect the word with a verb *licere*, 'to summon,' not actually found in Latin authors; they think of the lictors as summoning citizens to the *Comitia* (q.v.) or summoning accused persons before a magistrate. In kingly Rome the lictors were 12 in number and served as personal attendants of the King. Under the Republic the consul had 12, the dictators 24, the *magister equitum* 6, and the prætor 2. In the provinces, the proconsul had 12 and the proprætor 6. During the first century of the Empire the Emperor was attended by 12 lictors; but Domitian increased the number to 24. Afterward, however, the office was wholly abolished. Besides those attached to the persons of the civil magistrates, other lictors were assigned to the high religious functionaries. The chief priest (*pontifex maximus*) had 12, the priest of Jupiter (*flamen Dialis*) 6; and when a vestal virgin went through the streets she was accompanied by a lictor. During the Republic the lictors were men of plebeian rank, under the Empire largely freedmen (*libertini*). They wore the toga, and walked in single file before the magistrate, each bearing on his left shoulder the *fasces* (q.v.). They scourged offenders; in the earliest days, when the death penalty was still in force, they acted as executioners. Their duty was to clear the road for the magistrate, see that his authority was respected, and, in general, execute his orders. Consult Theodor Mommsen, *Römisches Staatsrecht,* vol. i (3d ed., Berlin, 1887), and the article "Lictor" in William Smith, *A Dictionary of Greek and Roman Antiquities,* vol. ii (3d ed., London, 1891).

LI′CUS. See Lech.

LID′DELL, Henry George (1811–98). An English classical scholar. He studied at Charterhouse School, then at Christ Church, Oxford, from which he graduated in 1833 with highest honors. He was headmaster of Westminster School from 1846 to 1855 and in 1862 became chaplain extraordinary to the Queen. In 1855 he was made dean of Christ Church and was vice chancellor from 1870 to 1874. He wrote a *History of Rome from the Earliest Times to the Establishment of the Empire* (1855), but he is best known as the author, together with Dean Scott, of the standard *Greek Lexicon* (1843; 8th ed., 1897), based on the Greek lexicon by Passow (q.v.). This is the best available Greek-English lexicon. Consult H. G. L. Thompson, *Henry George Liddell* (London, 1899).

LIDDELL, Mark Harvey (1866–). An American scholar, born at Clearfield, Pa. Educated at Princeton (A.B., 1887), at Oxford, and at Berlin, he was professor of English in the University of Texas (1897–1900), in the University of Louisville (1908–11), and at Butler University (1912–13), and then assistant professor at Purdue. His publications include, notably: *Works of Geoffrey Chaucer* (1898), edited in collaboration with A. W. Pollard, H. F. Heath, and W. S. McCormick; *An Introduction to the Study of English Poetry, being Prolegomena to a Science of English Prosody* (1902); *The Elizabethan Shakspere* (1903–), an edition with text in Elizabethan English, and fully and illuminatingly annotated; *Brief Abstract of a New English Prosody* (1914).

LID′DON, Henry Parry (1829–90). An English clergyman, generally acknowledged to have been the greatest pulpit orator of his time in the Church of England. He was born at North Stoneham, Hampshire, and educated at King's College School, London, and Christ Church, Oxford, where he took his degree in 1850. He was ordained deacon in 1852 and priest in 1853, proceeding to his first pastoral work at Wantage. In 1854 he was chosen to be the first vice principal of Bishop Wilberforce's new theological college at Cuddesdon; but the pronounced Church views which he had imbibed at Oxford from association with Pusey and Keble, his intimate friends through life, led to his resignation in 1859. He then became vice principal of St. Edmund's Hall and exercised a great and growing influence in university affairs. In 1870 he was appointed Ireland professor of exegesis, but resigned his chair in 1882 and took thereafter no active part in Oxford affairs, regarding the changes made by the Universities Commission as a repudiation of religious influence. From 1870 until his death he was a canon of St. Paul's, London, and here exercised, through the eloquence of his sermons and the power of his personality, his widest influence. He took a leading part in numerous important movements—in opposition to the Public Worship Regulation Act, in defense of the Athanasian Creed, in the foundation at Oxford of Keble College and the Pusey House, and in censure of what he considered the dangerous teachings of *Lux Mundi* (see Gore, Charles). At the time of his death he was engaged in the preparation of an elaborate life of Dr. Pusey; it was afterward edited for publication by Johnston and Wilson (London, 1893–97). He was elected Bishop of Edinburgh in 1886, but did not accept. He always remained a High-Churchman of the older school, and an opponent of liberalism in any of its forms. The most important of his published works are his Bampton Lectures *On the Divinity of Our Lord and Saviour Jesus Christ* (1866). Consult: A. B. Donaldson, *Five Great Oxford Leaders* (London, 1900); his *Life* by Russell (–1903); J. O. Johnston, *Life and Letters of H. P. Liddon* (ib., 1904); G. W. Russel, *Doctor Liddon* (Milwaukee, 1911).

LIDFORSS, lĭd′fôrs, Bengt (1868–1913). A Swedish botanist, born at Lund. He was educated at the University of Lund, became lecturer in botany there in 1897, professor at Upsala in 1910, and professor at Lund in 1911. He studied at several German universities, traveled in Italy and Bohemia, and obtained his doctorate in 1893. His special field for scientific investigations was plant physiology and microchemical anatomy. On those subjects he wrote important articles in *Acta Universitatis Lundensis* (1897, 1901, 1906); in *Vetenskabsakademiens förhandlingar* (1899, 1901–02); in *Arkiv för Botanik* (1905, 1907); in *Arskrift, Lunds Universitets* (1907, 1908). He also contributed to foreign scientific periodicals, and wrote popular articles on social, literary, and botanical subjects.

LID′GETT, John Scott (1854–). An English Wesleyan Methodist clergyman and editor, born at Lewisham. He was educated at University College, London, entered the ministry in 1876, and in 1902 was elected a member of the Legal Hundred. He was president of the National Council of Evangelical Free Churches of England and Wales in 1906 and 1907, president of the Wesleyan Methodist Conference in 1908–09, and was identified with civic interests. Together with the late W. F. Moulton he was the founder of Bermondsey Settlement in 1891, and thereafter was warden, residing at the settlement. In 1911 he became editor of the *Methodist Times* and joint editor of the *Contemporary Review.* He is author of *The Spiritual Principle of the Atonement,* his Fernley Lecture (1897; 4th ed., 1907); *The Fatherhood of God in Christian Truth and Life* (1902); *The Christian Religion: Its Meaning and Proof* (1907); *The Apostolic Ministry* (1909).

LIDNER, lēd′nĕr, Bengt (1757–93). A Swedish poet, born at Göteborg. When he entered the University of Lund (1774), he became the head of a coterie of youthful poets. Already dissipated, he had to leave the university at the end of a year and took his degree at Rostock. At Stockholm he published a collection of fables that attracted the attention of the King, Gustavus III, who sent him to Paris as secretary of the Ambassador, Creutz. While there he wrote his tragedy, *Erik XIV.* His most remarkable poems are *Grefvinnan Spastaras Död* and *Aret 1783,* and *Medea,* a tragedy. His complete works were published in 1788 and again, with a biography by Sander, in 1859 (8th ed., 1878).

LIDO, lē′dô. A range of low islands separating the lagune of Venice from the Adriatic. At the northern end lies the port of Venice, also called Lido.

LIE, lē, Jonas (1880–). An American landscape and figure painter. He was born in Norway, the nephew and namesake of the famous Norwegian writer, Jonas Lie. At 13 he came to America and studied in New York at the National Academy and the Art Students' League. He first exhibited at the academy in 1900 and was made associate in 1912. His early paintings are strongly individual and vigorously handled, yet at times inaccurate and crude. They present strong contrasts of light and shade and are imbued with a weird imagination and poetry of the North, his favorite subjects being storms, whirling winds, snow-covered wastes, or misty rivers. To this period belong "Wind Swept," "Autumn Gale," "A Winter Scene," "The Mill Race" (St. Louis Club); a few figure pieces, including "The Peasants' Dance," "The Emigrants' Wharf." Later, when his work had become more correct technically without losing any of its poetic qualities or effectiveness, he painted interpretations of familiar scenes, especially in and around New York. Such are: "From the Bridge" (1911); "Brooklyn Bridge," "A New York Canon," and "Morning on the River" (1912); "Fishing Boats at Sunrise" (Carnegie Institute, Pittsburgh). Among his latest achievements are paintings of the Panama Canal, of which there is a good example in the Metropolitan Museum of Art.

LIE, Jonas Lauritz Edemil (1833–1908). A Norwegian novelist, born at Eker, Nov. 6, 1833; died at Fleskum, July 5, 1908. He studied at Christiania, where he associated with Björnson and Ibsen, at first practiced law, and then gave himself to literature, journalism, and teaching. His first novel, *The Visionary* (1870; trans., 1894), was warmly received, and the Norwegian government accorded him a traveling stipend and soon afterward state support. He went to the Far North and to Rome, where he wrote *Sketches and Tales from Norway* (1872). His knowledge of the sea and coast life gave a peculiar flavor to *The Bark "Future"* (1872; trans., 1879) and *The Pilot and his Wife* (1874), the latter his most widely known novel. He received from the government the poet's pension and in the main lived abroad in German cities and in Paris, producing some score of good novels and two mediocre comedies. In the novels *The Slave for Life* (1883) marks a turning point. His earlier work—*Thomas Ross* (1878), *Adam Schrader* (1879), both urban; *Rutland* (1880), *Go Ahead!* (1882), both sea tales—is poetic and sympathetic. From 1883 onward—*The Family at Gilje* (1883), *A Maelstrom* (1884), *Eight Stories* (1885), *The Daughters of the Commodore* (1886), *Married Life* (1887; the last two translated into English), *Maisa Jons* (1888), *Poems* (1889), *Evil Powers* (1890), *Trolls I and II* (1891–92), *Niobe* (1893), *When the Sun Goes Down* (1895), *Dyre Rein* (1896), *Faste Forland* (1899), *When the Curtain Drops* (1901), *Ulfunger* (1903), and the dramas *Merry Wives* (1893), *Lindelin* (1897), and *Wulffie & Co.* (1901). Lie falls under the domination of the French Naturalistic school. In seeking to be more true to real life he fixes his eyes on its less pleasant aspects, but sympathy and humor never desert him when he writes of the sea and family life. Many of Lie's stories have been translated into English, German, and other languages. Lie's return to Norway in 1893 after 12 years' absence was celebrated as a national festival. His *Complete Works* (*Samlede Verker*) were published in 15 volumes (Copenhagen, 1902–04; translated into Swedish, 1908–11). Consult: A. Garborg, *Jonas Lie* (2 vols., Christiania, 1893); H. Bang, in *Tilskueren* (Copenhagen, 1908); E. Lie, *Jonas Lies Oplevelser* (Christiania, 1908).

LIE, Sophus (1842–99). A Norwegian mathematician, born at Nordfjordeid, near Bergen. He studied at Christiania and, on receiving a traveling scholarship in 1869, visited Germany, Italy, and France. In the following year he began teaching at Christiania. He received his doctor's degree in 1871, presenting a remarkable thesis, "On a Class of Geometric Transformations." From 1872 to 1886 he held the chair of mathematics (which was especially created for him) in the University of Christiania and was then called to Leipzig to succeed Klein. In 1898 he was again called to the University of Christiania and died there in January of the following year. Lie's greatest work was in the theory of differential equations and in his discovery of continuous transformation groups. His best-known works include: *Theorie der Transformationsgruppen* (3 vols., 1888–93); *Vorlesungen über Differentialgleichungen mit bekannten infinitesimalen Transformationen*, and also *Ueber continuierlichen Gruppen* (ed. by Scheffers, 1891, 1893). He was member of many scientific societies, and his mathematical discoveries gained him the much-coveted honor of the Lobatchewsky prize. For a complete list of his works, consult Friedrich Engel, "Sophus Lie," in *Bibliotheca Mathematica*, vol. i (3d series, Leipzig, 1900); for biography, Darboux, in the *Comptes Rendus de l'Académie des Sciences*, vol. cxxviii (Paris, 1899), translated in the *Bulletin of the American Mathematical Society* (New York, 1899); Engel, in the *Jahresbericht der Deutschen Mathematiker-Vereinigung*, vol. viii (Berlin, 1900). C. Störmer published a list of part of Lie's works in manuscript (in all over 20,000 folio pages) in *Christiania Videnskabsselskabs Forhandlinger* (1904).

LIEB, lēb, John William, Jr. (1860–). An American mechanical engineer, born at Newark, N. J. He graduated M.E. from Stevens Institute of Technology in 1880. Engaged by Thomas A. Edison to assist in the installation of electrical equipment at the first electrical station in the United States, the old Edison Station at Pearl Street, New York, in 1882 Lieb became the first electrician of the Edison Electric Illuminating Company of New York, a connection which he resumed in 1894 after having installed the Edison Underground System at Milan, Italy (1883), and subsequently the trolley system there. He became vice president of the New York Edison Company, president of the Electrical Testing Laboratories, and director of other corporations. In the year 1904–05 he was president of the American Institute of Electrical Engineers.

LIEBEN, lē′ben. A northeastern suburban district of the city of Prague, Austria. It is situated at the confluence of the Rokytnitzbach and the Moldau, on the right bank of the latter (Map: Austria-Hungary, D 1). Weaving, spinning, tanning, dyeing, lace making, and manufactures of machinery, chemicals, cardboard, colors, pipes, and gloves are the leading industries. Pop., 1900, 21,300; 1910, 27,034.

LIEBENSTEIN, lē′ben-stīn. A ruined castle on the Rhine, near Saint-Goar, which, with the neighboring castle of Sterrenberg, is associated with a legend of two brothers estranged through their love for their foster sister Hildegarde. The castles are hence known as the Two Brothers.

LIEBER, lē′bẽr, Ernst (1838–1902). A German politician, leader of the Clericals. He was born at Camberg, studied law and philosophy in Würzburg, Munich, Bonn, and Heidelberg, and, after taking a prominent part in the politics of Hesse-Nassau, was chosen to the Prussian House of Deputies in 1870 and to the Reichstag in 1871. He was one of the founders of the Centrum in each of these Houses and after Windhorst's death succeeded in part to its leadership. As a democratic Clerical, he opposed in 1893 the efforts of the moderate Clericals to come to an agreement with the government, but afterward he practically accepted their programme.

LIEBER, Francis (1800–72). A German-American publicist. He was born in Berlin, March 18, 1800. In 1815 Lieber enlisted in the Prussian army, fought at Ligny and Waterloo, and in the attack on Namur was severely wounded. After Napoleon's overthrow he studied in Berlin and, becoming imbued with liberal political ideas, was in 1819 accused of plotting against the government and imprisoned. The charges never came to trial, but on his discharge he was forbidden to study at the Prussian universities. In 1820 he took his degree at Jena. On the outbreak of the Greek revolution, in 1821, he went to Greece to take part in the struggle. An account of his experiences is given in his *Journal in Greece* (1823). In 1822 he found his way to Rome, where he became a tutor in the family of the historian Niebuhr. With him Lieber returned to Berlin and was rearrested on allegations of disloyalty based on the old charges. After a short imprisonment at Köpenick, enlivened by the composition of a number of poems, he was released through the efforts of his friend Niebuhr and, wearied by this constant persecution, left his native country in 1825 forever. For a short time he resided as a teacher in London, and in 1827 he embarked for the New World. His first work, the editing of the *Encyclopædia Americana,* was completed during his five years' residence in Boston (1827–32). The next two years were spent in Philadelphia, where he was interested in educational plans in connection with Girard College. In 1835 he removed to Columbia, S. C., where he occupied the position of professor of political economy in the South Carolina College for 20 years; and here he produced his most important works: *A Manual of Political Ethics* (1838); *Legal and Political Hermeneutics* (1839); *Civil Liberty and Self-Government* (1852). In his line of investigation Lieber stands second to none. Such writers and jurists as Wittermaier, Bluntschli, Laboulaye, Story, and Kent, recognized in him a kindred mind. The spirit of his work is indicated in his favorite motto, *Nullum jus sine officio, nullum officium sine jure* (No right without its duties, no duty without its rights). In 1856 Lieber was called to Columbia College, New York, to take the chair of political economy, and in 1860 accepted the chair of political science in the Columbia Law School, giving up his chair of economics. During the Civil War he served the government by preparing, at the request of the War Department, a set of "Instructions for the Government of the Armies of the United States in the Field," which is regarded as an authority on the usages of civilized warfare and forms the basis of a number of military codes to-day. It is known as "General Order No. 100" and is quoted often as authoritative. Lieber was a member of the French Institute and of numerous other learned societies in America and Europe. He died in New York, Sept. 2, 1872. Among his voluminous minor writings the following are the most noteworthy: *Reminiscences of Niebuhr; Laws of Property; Penal Laws and the Penitentiary System; Prison Discipline; The Origin and Development of the First Constituents of Civilization; Great Events Described by Great Historians.* His memoir was written by Perry, published in Boston, 1882, and a discriminating estimate of his career was published by Thayer in 1873. Lieber's *Miscellaneous Writings* were collected by Gilman and published in two octavo volumes, Philadelphia, 1881. His collection of books were sold to the University of California, and his manuscripts were deposited in Johns Hopkins University.

LIEBER, Guido Norman (1837–). An American soldier and publicist. He was born at Columbia, S. C., where his father, Francis Lieber (q.v.), was a professor in South Carolina College. He graduated at that institution in 1856 and at Harvard Law School in 1858 and at the outbreak of the Civil War was practicing law in New York City. He then obtained an appointment as a lieutenant in the regular army, was assigned to the Eleventh Infantry, was advanced to the rank of regimental adjutant, and served in McClellan's Peninsular campaign, in which he was brevetted captain for gallantry at the battle of Gaines's Mill (June 27, 1862). At the second battle of Bull Run he served as an aid on General Pope's staff. Appointed major and Judge Advocate in 1867, he was assigned to the Department of the Gulf, receiving further brevets of major for services in the Red River campaign and lieutenant colonel for general services during the war. From 1878 to 1882 he was professor of law at West Point. He became Assistant Judge-Advocate-General, with rank of colonel, in 1884, and from 1895 to 1901 was Judge-Advocate-General of the United States army, in which capacity he was one of the most valuable advisers of President McKinley during the Spanish-American War. His publications include several important treatises on the laws of war, such as *The Use of the Army in Aid of the Civil Power* (1898) and *Remarks on the Army Regulations* (1898).

LIEBER, or **LIEBLER,** Thomas. A Swiss physician and theologian, better known under the Latinized form of his name, Erastus (q.v.).

LIEBERMANN, lē′bẽr-män, Max (1847–). A German painter and etcher, one of the foremost artists of his time. He was born at Berlin, July 29, 1847, of Jewish parentage, and studied under Steffeck in Berlin, under Thumann at Weimar, and under Munkaczy in Paris from 1872. But the strongest influences in the formation of his art came from the Barbizon painters, in particular from Millet, and later from Josef Israëls, with whom he was associated during frequent sojourns in Holland. There he copied the works of Frans Hals and studied the life of the peasantry, who long furnished the themes of his finest productions. After residing from 1879 to 1884 in Munich, he settled in Berlin, where, in spite of adverse criticism, he became the recognized leader of the Secessionist movement in northern Germany. He was the first to introduce the *plein air* methods of the Barbizon school, modified later by Impressionistic principles. His art is individual, simple, and direct. Although at first labored in technique, it shows great power of rendering movement and effects of atmosphere and light. His favorite themes are from the life of the working classes, for which reason he has been frequently termed "an apostle of ugliness." In his earliest paintings, such as "Women Plucking Geese" (1872, National Gallery, Berlin), the influence of Courbet is plainly visible in the subdued color; but his development, starting with "Laborers in a Turnip Field" (1876), was constant, and in later years he worked in bright impressionistic colors. Among his Dutch themes are: "The Asylum for Old Men" (1881); "The Cobbler's Shop" (1881, Berlin); "The Flax Barn, Laren" (1887, Berlin); "The Net Menders" (1889, Hamburg); "Woman with Goats" (1890, New Pinakothek, Munich); "The Hog Market, Haarlem" (1891, Mannheim). A good example of modern genre is his "Country Tavern, Bavaria" (1893, Luxembourg, Paris). His more recent works include: "Polo Players" (1902); "Going to School, Edam" (1904, Königsberg); "Summer Evening on the Alster" (1910, Dresden); "Dutch Landscape" (1912, Munich); and many convincing portraits, such as Dr. Bode (National Gallery, Berlin); Professor Virchow, Burgomaster Petersen, of Berlin, and Gerhart Hauptmann (1913). His etchings are masterly yet simple combinations of lines and strokes, and his drawings are also highly valued. He became professor at the Berlin Academy, received gold medals at Berlin, Munich, Paris, Dresden, Antwerp, and Venice, was chosen Knight of the French Legion of Honor and of Italian, Swedish, Belgian, and other orders; member of the Prussian and Saxon academies, and honorary member of the Société Nationale des Beaux-Arts, Paris, the Société Royale, Brussels, and the Bavarian Academy.

Singer, *Zeichnungen von Max Liebermann* (Leipzig, 1912); Karl Graul, *Max Liebermann's Radierungen* (Berlin, n. d.); Gustav Schiefler, *Das graphische Werk von Max Liebermann* (ib., 1914).

LIEBESMAHL DER APOSTEL, lē′bes-mäl dēr ȧ-pȯs′tel, DAS (Ger., The Love Feast of the Apostles). An oratorio by Wagner (q.v.), first produced in Dresden, July, 1843; in the United States in 1859 (New York).

LIEBESVERBOT, DAS, däs lē′bes-fĕr-bōt′ (Ger., Interdiction of Love), or **DIE NOVIZE VON PALERMO**, dē nȯ-vē′tse fȯn pȧ-lĕr′mȯ. An early opera by Wagner (q.v.), first produced in Magdeburg, March 29, 1836.

LIEBHARD, lēp′härt, JOACHIM. The correct name of the German classical scholar generally known as Joachim Camerarius (q.v.).

LIEBIG, lē′bĭK, JUSTUS VON, BARON (1803–73). One of the greatest chemists of the nineteenth century. He was born at Darmstadt, Germany, the son of a dealer in dyestuffs. He early showed a strong predilection for natural science. At the age of 15 he became apprenticed to an apothecary at Heppenheim, near Darmstadt. Soon after he entered the University of Bonn, then went to Erlangen, where he took his doctor's degree in 1822. In that year he published a paper on fulminating mercury and in 1823 went to Paris, where, by further researches on the fulminates, he soon attracted the attention of Alexander von Humboldt. Humboldt introduced Liebig to Gay-Lussac, Thénard, and Dulong, and the young German chemist was hospitably received in the laboratory of Gay-Lussac. At the recommendation again of Humboldt, Liebig was made professor of chemistry at the University of Giessen (1824), where he remained for more than a quarter of a century, attracting students from all parts of Germany and from foreign countries. In 1845 the Grand Duke of Hesse raised him to the rank of Baron. In 1852 he became professor of chemistry at Munich and in 1860 president of the Academy of Sciences and curator general of the scientific collections of Bavaria. He remained in Munich until his death.

When Liebig began his career, chemistry was in its infancy. Above all, organic analysis was in an extremely undeveloped state, so that a great deal of ingenuity was required in carrying out what are now very simple analytical determinations. At the time of Liebig's death chemistry, both pure and applied, had developed beyond all expectations; and Liebig had contributed more than any one of his contemporaries to its prodigious growth. Liebig established the first laboratory where students might receive a thorough practical training in chemistry, to supplement the instruction given in the lecture room (see LABORATORY), and in Liebig's own laboratory some of the most distinguished nineteenth-century chemists were trained. Another great service was his introduction of the well-known method of organic analysis. (See CHEMISTRY, *Organic Chemistry*.) The number of carbon compounds discovered and studied by Liebig himself was very great. He analyzed many important natural alkaloids; investigated the action of chlorine on alcohol and discovered chloral and chloroform; studied the products of oxidation of alcohol and discovered aldehyde; determined the basicity of many organic acids; investigated the chemical composition of urine and the derivatives of uric acid; analyzed the juice of flesh, etc. His theory of the constitution of alcohol, ether, and chloroethane, and the celebrated research carried out jointly with Wöhler (q.v.) on the benzoyl compounds, gave a powerful impulse to the development of chemical theory. Among his contributions to chemical technology may be mentioned his method of making the cyanide of potassium, a compound extensively used in electroplating and in the manufacture of ferrocyanides. The discovery of aldehyde, mentioned above, has led to important improvements in the manufacture of mirrors and of vinegar.

The phenomena of animal and vegetable life formed one of Liebig's favorite branches of research, and he was the first to advance the theory that the activity of physical and chemical forces is the same in the organized as in the mineral world. He proved experimentally that animal heat is nothing but the energy liberated by the combustion in the organism mainly of fats and carbohydrates. Foods which serve as fuel and supply the heat of the body he termed respiratory foods. Nitrogenous substances, which—as he showed—serve to build up the tissues of the body, he termed plastic foods. He was also the first to prove that the transformation of inorganic into organic substances takes place exclusively in the organisms of plants, from which animals receive ready-formed the principal substances of their flesh and blood. Plants, on the other hand, receive their nourishment from the soil and the air, the former supplying them with the sulphates, sulphites, and phosphates of sodium, potassium, calcium, magnesium, and iron; while the atmospheric air supplies them with carbonic acid, water, ammonia, and nitric acid. It thus became clear that, in order to maintain the fertility of the soil, the saline ingredients necessary for the growth of plants must from time to time be restored to it, either in isolated form or in the form of the sewage of towns, in which they are contained in considerable quantity. The importance to agriculture of the manufacture of saline fertilizers, which has thus originated in Liebig's researches, is inestimable, and Liebig may justly be considered as one of the founders of agricultural chemistry. See CHEMISTRY, AGRICULTURAL.

Liebig's *Chemistry in its Application to Agriculture and Physiology* appeared in Brunswick and in London in 1840. The second part of this epoch-making work was published under the title *The Natural Law of Husbandry* (Brunswick, 1862; London, 1863). His *Animal Chemistry, or Chemistry in its Application to Physiology and Pathology* appeared in 1842 (Brunswick and London; 3d Ger. ed., Brunswick, 1846). An English translation of his paper on foods appeared in London in 1847, under the title *Researches on the Chemistry of Food.* The celebrated *Handbook of Organic Analysis* was published in Brunswick and in London in 1853. Liebig's publications further include: *Handwörterbuch der Chemie,* the compilation of which he began in conjunction with Poggendorff (9 vols., Brunswick, 1836–64, and a later edition); *Handbuch der organischen Chemie* (Heidelberg, 1839–43); *Theorie und Praxis in der Landwirtschaft* (Brunswick, 1856); *Naturwissenschaftliche Briefe über die moderne Landwirtschaft* (Leipzig, 1859), etc. The celebrated *Chemische Briefe* (Familiar Letters on Chemistry) first appeared in the *Augsburger Allgemeine Zeitung* (6th Ger. ed., Leipzig, 1878); it has been translated into most European languages. The list of Liebig's scientific papers comprises more than 300 titles, each paper forming a valuable contribution to organic science. In his private life Liebig was kind and hospitable, noble in thought and generous in feeling. Numberless honors were bestowed upon him. Consult: A. W. von Hofmann, *The Life-Work of Liebig in Experimental and Philosophic Chemistry* (London, 1876); W. A. Shenstone, *Justus von Liebig: His Life and Work, 1803–1873* (New York, 1895); Wilhelm Ostwald, "Justus Liebig," in *Grosse Männer* (Leipzig, 1909); Jakob Volhard, *Justus von Liebig* (2 vols., ib., 1909).

LIEBKNECHT, lēp′knĕkt, KARL (PAUL AUGUST FERDINAND) (1871–1919). A German Socialist leader, son of Wilhelm Liebknecht. He was born at Leipzig, where he studied law; and he finished in 1893 his legal studies at Berlin, where he became a practicing attorney. He was chosen selectman for the city of Berlin in 1902, became a member of the Prussian House of Deputies in 1908, and in 1912 he was elected to the Reichstag, where he was soon recognized as a leader among the Socialist deputies. In 1913 he made charges before the Reichstag that led to the revelation of the Krupp scandals, and in 1914 he was the only member of that body who voted against the $1,250,000,000 war credits. The other German Socialist deputies repudiated his action. He is author, besides *Vorbehaltszahlung und Eventualaufrechnung* (1899), of *Militarismus und Antimilitarismus* (1907; 3d ed., 1911), which was forbidden by the Imperial government to be circulated in Germany and was made the basis of a charge against Liebknecht of high treason. He was convicted in 1907 and sentenced to 18 months in prison. In March, 1915, despite his protests, he was mustered into the army and assigned to service in Alsace.

LIEBKNECHT, WILHELM (1826–1900). A German Social Democrat and agitator, born at Giessen. He studied philology and philosophy at Giessen, Berlin, and Marburg. In 1848 he took part in the revolt in Baden and was imprisoned, but escaped in May of 1849, going first to Switzerland and then to London. There he earned his living as correspondent for German newspapers and, as a member of the Communistenbund, associated with Marx and Engels. In 1862 he took advantage of the amnesty, returned to Germany, and began to write for the *Norddeutsche Allgemeine Zeitung.* But in 1865 he was banished from Prussia for Socalistic agitation. Two years later he was elected to the North German Parliament from Leipzig, and in 1868 he began to edit the *Demokratisches Wochenblatt,* in which he attacked Bismarck so bitterly that in 1872 he was imprisoned for two years, with his fellow editor Bebel (q.v.). But before he was released he had been elected to the German Reichstag (1874). Save for brief periods he kept his seat there until his death. In 1879 he was elected to the Second Chamber of the Saxon Legislature. He was editor of the Berlin *Vorwärts* from 1890 to 1900 and in 1895 was imprisoned for four months on the charge of lese majesty. He wrote: *Zur Grund- und Bodenfrage* (1876; 2d ed., 1885); *Ein Blick in die neue Welt* (1887), relating his impressions of a trip to America made in that year; *Robert Blum und seine Zeit* (2d ed., 1890); *Geschichte der französischen Revolution* (1890); *Die Emser Depesche* (7th ed., 1899); *Robert Owen* (1892); *Volksfremdwörterbuch* (13th ed., 1913). Two of his works have appeared in English, *Karl Marx: Biographical Memoirs,* translated by E. Untermann (Chicago, 1906), and *No Compromise, No Political Trading,* translated by A. Simons and M. Hitch (Chicago, 1911).

LIEBLEIN, lēb′līn, JENS DANIEL CAROLUS (1827–1911). A Norwegian Egyptologist, born at Christiania. He studied in the University of Christiania in Berlin under Brugsch and Lepsius, in Paris and Turin at the expense of the state, and later in London and Leyden. He was made professor at Christiania in 1876. As representative of Norway, he was present with Henrik Ibsen at the opening of the Suez Canal (1869), being Ismail Pasha's guest, and he traveled in Egypt again in 1887–88 and 1899–1900. His earliest publication was *Aegyptische Chronologie* (1863), which did much to systematize that branch, especially in the sequel; *Recherches sur la chronologie égyptienne d'après les listes généalogiques* (1873). His other works include: *Dictionnaire des noms hiéroglyphiques, en ordre généalogique et alphabetique* (1871), which is supplemented by *Hieroglyphisches Namenwörterbuch* (1891); *Gammelægyptisk Religion* (3 vols., 1883–85); *Egyptian Religion* (1884); *Handel und Schiffahrt auf dem rothen Meere in alten Zeiten* (1886); *Le livre égyptien: Que mon nom fleurisse* (1895), a comparison between "Papyrus Lieblein" and 20 other papyri which give the same text; and *Recherches sur l'his-*

toire et la civilisation de l'ancienne Egypte (3 vols., Leipzig, 1910–14).

LIEBLING, lēp′lĭng, Emil (1851–1914). A German-American pianist and composer, born in Pless, Silesia. He studied music and the piano with Ehrlich, Dorn, and Kullak in Berlin, and with Dachs in Vienna. In 1867 he came to the United States, where he settled as a music teacher. Upon a subsequent visit to Europe he studied under Liszt at Weimar. After 1872 he was identified with the musical life of Chicago. His compositions include piano pieces and songs, most of which have met with considerable popular favor. He died in Chicago.

LIEBMANN, lēp′män, Otto (1840–1912). A German philosopher, born at Löwenberg and educated at Leipzig and Halle. He was made professor at Strassburg (1872) and went to Jena in 1882. He retired in 1911. His writings include: *Vier Monate vor Paris*, a journal published anonymously (1871); *Kant und die Epigonen* (1865; new ed., 1912), in which, criticizing the followers of Kant, he urged a return to their master and became the first of the Neo-Kantians; *Ueber die Freiheit des Willens* (1866); *Ueber den objektiven Anblick* (1869); *Zur Analysis der Wirklichkeit* (4th ed., 1911); *Gedanken und Thatsachen* (4th ed., 1904); *Klimax der Theorieen* (1884); *Geist der Transcendentalphilosophie* (1901); *Grundriss der kritischen Metaphysik* (1901); *Immanuel Kant* (1904).

LIEBRECHT, lēb′rĕKt, Felix (1812–90). A German linguist and folklorist, born at Namslau. Educated at Breslau, Munich, and Berlin, he became professor of German at the Athénée Royal in Liége in 1849 and retired in 1867. He was the author of many valuable translations with excellent notes—e.g., of Giambattista Basile's *Pentamerone* (1846), with an introduction by Jakob Grimm; of *Barlaam und Josaphat*, by Damascenus (1857); of Dunlop's *Geschichte der Prosadichtungen* (1851); and of the *Otia Imperialia* of Gervase of Tilbury (1856). Various monographs of his were collected under the title *Zur Volkskunde* (1879).

LIEBREICH, lē′brīK, Oskar (1839–1908). A German pharmacologist. Born at Königsberg, he studied chemistry in Wiesbaden under Fresenius, and then in Berlin, and medicine in Königsberg, Tübingen, and Berlin. At the University of Berlin he became assistant in 1867, professor of therapeutics in 1868, and director of the pharmacological institute in 1872. He introduced the method of phaneroscopic illumination for the study of lupus; showed the value of cantharidin in tuberculosis, of mercuric formamide and of lanolin in syphilis, of butylchloral hydrate and of ethylene chloride as anæsthetics, and of chloral hydrate as a soporific; and in 1865 gave the name "protagon" to a proximate principle discovered in the brain and in blood corpuscles. Liebreich edited the *Therapeutische Monatshefte* (1887 et seq.) and the *Encyklopädie der Therapie* (1895–1900), and with Langgaard published a *Kompendium der Arzneiverordnung* (6th ed., 1907). Among his other works are *Ueber die Wirkung der Borsäure und des Borax* (1903); *Ueber Beziehungen der pharmakodynamischen Therapie zu anderen Wissenschaften im 19. Jahrhundert* (1904); *Zur Frage der Bor-Wirkungen* (1906).

LIECHTENSTEIN, lĭK′ten-shtīn. An independent principality, lying between Austria and Switzerland, with the exception of Monaco and San Marino the smallest independent state of Europe (Map: Switzerland, D 1). It is bounded by the Austrian Crownland of Vorarlberg on the northeast and east, and on the south and west by the Swiss cantons of Grisons and Saint-Gall respectively. The Rhine River marks the western boundary. The area is 61.4 square miles. The surface is extremely mountainous except in the western part. The country is traversed north and south by two ramifications of the Rhætian Alps and reaches in the Naafkopf an altitude of about 8440 feet. The valley of the Samina, a tributary of the Ill, separates the mountain chains in the south. The climate is generally mild and healthful, but sudden storms are frequent. Agriculture, gardening, stock raising, weaving, and the production of wine and of wooden articles are the principal industries. The principality joined the Austrian customs union by the Treaty of 1852, renewed in 1876. Its annual share of the customs receipts must not be less than $9000, but is usually about $20,000.

The principality is a constitutional monarchy, hereditary in the male line. The constitution, first adopted in 1862 and modified in 1878, 1895, and 1901, vests the legislative power in the Prince and in a Landtag of 15 members, three appointed by the Prince and 12 elected indirectly, for four years. The highest administrative authority is the Chancellery at Vienna, to which the administration at Vaduz, the capital, is subordinate, and which serves also as a court of second instance. The highest judicial authority of the principality is the Supreme Court at Innsbruck. The inhabitants are free from military duty as well as from direct taxes. The revenue and expenditure for 1912 amounted to $174,800 and $161,600 respectively. The principality has no public debt and no mint; the Austrian currency and the Austrian weights and measures and postal system are used. Liechtenstein forms a part of the Roman Catholic bishopric of Chur, Switzerland. Pop., 1906, 9650; 1911, 10,716. The inhabitants are German and nearly all Roman Catholic. The population of Vaduz is about 1400. The reigning house dates from the twelfth century. In 1719 the two principalities of Vaduz and Schellenberg were recognized by the Emperor Charles VI as the Principality of Liechtenstein. Upon the break-up of the Holy Roman Empire in 1806, it joined the Confederation of the Rhine; from 1815 to 1866 it belonged to the German Confederation; since the latter date it has been politically independent, though economically allied with Austria. The Prince of Liechtenstein resides for the most part at Vienna.

LIED, lēt (Ger., song). A German term which has no equivalent in any other language, denoting an art form established by Franz Schubert and extensively cultivated since then by composers of all ranks and nationalities. The Germans also use the term *Kunstlied* to distinguish the art form of Schubert from the *Volkslied*, or folk song, from which it is a natural development. During the latter half of the eighteenth century several German composers began to compose simple songs which were consciously modeled after the old folk songs and were called *volkstümliche Lieder*. J. A. Hiller (1728–1804) may be regarded as the father of this style. A. T. Schulz and his followers created the short symmetrical *liedform*. By means of this the composer was enabled on the one hand to preserve the unity of mood (*Stimmung*), on the other to reproduce faithfully the spirit of the individual word by means of proper declamation and harmonization. Schubert's rare genius raised this simple form at once into the domain of the highest musical art. The next step was the broadening of the strophic form into the *durchkomponierte Lied.* In the strophic form all the verses are set to the same music. The *durchkomponierte Lied* pays more attention to the individual word by allowing different musical themes for different stanzas. Schubert succeeds in preserving artistic unity by various means, repetition of some musical phrase, insistence upon some rhythmic or melodic figure in the piano part, etc. Schumann, Franz, Jensen, and Brahms developed the form further by making the piano take an important part in the thematic development, raising it above the rank of a mere accompanying instrument, which it generally is even with Schubert. Hugo Wolf, practically neglected during his lifetime, has recently come to be recognized more and more, and many competent authorities regard him not only as one of the most important figures in the history of the lied, but even as the greatest master of that form. In scrupulous adherence to the metrical accent and correct declamation of the text he surpasses all predecessors. By transferring Wagner's principle of the music drama to the lied Wolf makes the instrument the prime factor in the musical interpretation. Richard Strauss, whose songs contain some of his most divinely inspired utterances, follows very much along the lines of Wolf. Other great names, though not so important for the actual development of the lied, are those of Liszt, Tschaikowsky, and Grieg. Consult: H. Bischoff, *Das deutsche Lied* (Berlin, 1905); W. K. von Jolizza, *Das Lied und seine Geschichte* (Vienna, 1910); Herman Kretzschmar, *Geschichte des neuen deutschen Liedes* (Leipzig, 1911). See ARIA.

LIEDFORM, lēt'fōrm (Ger., song form). A musical form very much employed in instrumental music and borrowed originally from the strophic lied. It consists of three sections with two themes, A—B—A. See FORM.

LIÉGE, lē'ĕzh' (Walloon, *Lige*, Flem. *Luik*, Ger. *Lüttich*). The capital of the Belgian province of the same name and one of the most important manufacturing centres of Belgium, situated on both banks of the Meuse at its confluence with the Ourthe, in a region remarkably picturesque (Map: Belgium, D 4). Liége is the centre of the Walloon country. The hills which form the background of the city on both sides of the river are fortified by a circle of 12 detached forts, six on the right side of the river and six on the left. They were built from 4 to 6 miles from the city, at an average distance of 4 miles apart; they were constructed in concrete with casemates and with automatically disappearing heavy guns. The Meuse makes an island at Liége and divides the city into two parts—the old town on the left bank, containing the principal public buildings, and the new town on the right bank, being given up chiefly to manufacturing industries. The river is spanned here by six main bridges, of which the Pont des Arches is the most attractive. Liége has good water works, electric lighting, and excellent local transportation. The centre of the city, the Square d'Avroy, is splendidly laid out and is adorned with an equestrian statue of Charlemagne. Chief among the churches is the fine cathedral of St. Paul, founded in 968 and completed in 1528. It is built mainly in Gothic style, has a richly ornamented interior, a noteworthy pulpit, and paintings. The former cathedral, St. Lambert's, was sacked and destroyed by the French in 1794. The splendid church of St. Jacques dates from 1056 and possesses an attractive interior; the basilica of St. Barthélemy is of the twelfth century and has a remarkable bronze font of the year 1112. Among other churches may be mentioned St. Croix, a curious pile built in 970, but repeatedly restored since then; and St. Martin, founded in 962 and rebuilt in Gothic style in 1542. Perhaps the most striking building of Liége is the Palais de Justice. It was constructed as an episcopal palace in 1508–40 and was entirely restored in 1848–56. The exterior is ornamented with sculptures. The most interesting part of the building is the two interior courts surrounded by vaulted arcades and unique columns, a mixture of Gothic and Renaissance. Some of the rooms in the building are furnished with royal splendor. The building contains, besides the law court and the provincial administration offices, an interesting archæological museum. The theatre (1808–22) is modeled after the Odéon in Paris. In front of it stands a bronze statue (by Geefs, 1842) of the composer Grétry, who was born in Liége. The university buildings are also modern and scattered all over the city. The university, founded in 1817 by the Dutch government, is a state institution, has faculties of philosophy, jurisprudence, mathematics and natural sciences, medicine and technology, with an attendance of about 2861 students in 1911–12. Its natural-history museum is rich in the remains of antediluvian animals found in caverns in the district. Attached to the university are a library of 405,000 volumes, anatomical and physiological institutes, a chemical laboratory, and a zoölogical institute. The other important educational institutions of Liége are the Ecole des Mines et des Arts et Manufactures and the Ecole Electro-Technique, both affiliated with the university; a seminary for teachers, an episcopal seminary, an academy of art, a royal conservatory of music (attended by 1042 students in 1911 and famous for its teaching of stringed instruments), institutions for the blind and the deaf and dumb, and a number of scientific organizations.

The municipal museum, situated in the old cloth hall, contains a small collection of paintings, chiefly by native artists. Liége has both zoölogical and botanical gardens. From the lofty citadel, erected in 1650, there is a magnificent view. Industrially the city is noted for its extensive manufactures of weapons, which give employment to a large portion of the artisan population. A characteristic feature about this branch of production is that it is still carried on as a house industry. Naturally, however, it has begun to feel the effect of the competition of other countries where the industry is more modern in its organization. Among the larger weapon factories may be mentioned the royal gun factory and cannon foundry. The proximity of rich coal mines makes Liége an important iron and steel centre, its products including different tools and instruments, heavy machinery, needles, nails, etc. Watches, gold and silver articles, mirrors, cloth, leather, paper, oil, and chicory are also among the manufactures, and Liége has large zinc foundries. Its commerce is of great extent; there is considerable navigation in the port. Liége is the seat of a bishop and a United States consul. Pop. (commune), 1890, 147,660; 1900, 157,760; 1910, 167,521; 1913, 170,634, mostly Roman Catholics. The population of the city and the suburbs (Angleur, Bressoux, Grivegnée, Herstal, and Ougrée) was 190,744 in 1890, 214,838 in 1900, and 242,357 in 1910.

The city is believed to have had its origin in a Roman colony. It became the residence of a bishop at the beginning of the eighth century, and its history may be epitomized as a continual struggle between its citizens and the bishops, who were princes of the Holy Roman Empire. The latter frequently employed foreign armies to crush the rebellious spirit of the townspeople. In 1468 it was taken by Charles the Bold of Burgundy and later by Maximilian I. During the seventeenth century it was seized repeatedly by the French, and it fell before Marlborough in 1702. In 1801 it was ceded to France by the Treaty of Lunéville. In 1815 it was annexed to the United Netherlands, and in 1830 it was incorporated with Belgium. Liége was the scene of the first real battle of the European War which began in 1914. After a futile attempt to take it by assault the Germans were obliged to intrench and bring up heavy siege artillery. Although the invaders early entered the city itself, it was only after a two weeks' bombardment that the forts, which were not destroyed by the retreating Belgians, were finally captured. See WAR IN EUROPE.

Consult: Henry Sage, *Les institutions politiques du pays de Liége au XVIIIe siècle, leur décadence et leur dernier état* (Paris, 1908), containing a bibliography; Godefroid Kurth, *La cité de Liége au moyen-âge* (3 vols., Brussels, 1909–10); for the siege of 1914, Paul Hamelius, *The Siege of Liége: A Personal Narrative* (London, 1914), and J. M. Kennedy, "The Campaign around Liége," in *Daily Chronicle War Books*, vol. iv (ib., 1914).

LIEGNITZ, lēᴋ′nĭts. A town in the Province of Silesia, Prussia, capital of the former Principality of Liegnitz, near the confluence of the Schwarzwasser and the Katzbach, 40 miles by rail west-northwest of Breslau (Map: Germany, F 3). The city proper is surrounded by promenades and has many fine suburbs. The principal churches are St. John's, containing monuments of the dukes of Liegnitz and Brieg, of the house of Piast, and SS. Peter and Paul, dating from the fourteenth century and recently restored. The royal castle, destroyed by fire in 1835, has been restored and is used as a government building. Liegnitz has a new city hall, a municipal Gymnasium founded in 1309, an academy for the children of noblemen, an agricultural school, a seminary for female teachers, a museum of antiquities, and a theatre. The manufactures include cloth, machinery, pianos, shoes, tobacco, oil, woolens, wagons, glazed brick, cutlery, gloves, lumber, lamps, whips, and cabinetwork. Vegetables are extensively cultivated. Liegnitz is first mentioned in 1004 and was after 1164 the residence of the dukes of Liegnitz. Near Liegnitz, on the battlefield known as the Wahlstatt, the Silesians, Poles, and Teutonic Knights fought a bloody battle with the Mongols in 1241. As a fortified town, it figured prominently in many wars. It has been in possession of Prussia since 1742. Here in 1760 Frederick the Great defeated the Austrians under Laudon. Pop., 1900, 54,839; 1910, 66,620.

LIEN, lē′*en* *or* lēn (Fr. *lien*, bond, from Lat. *ligamen*, band, from *ligare*, to bind). In law, a security or hold over goods or land, and the right to retain or take the same for a debt which is due. Liens exist (1) at common law, (2) in equity, (3) in admiralty, and (4) by statute; and each of these differs from the others in character and in its effect upon the property. 1. Liens upon chattels were recognized and enforced at common law in favor of innkeepers, common carriers, attorneys, warehousemen, factors, and any one who had performed work upon a chattel in his possession at the owner's request—all of which attached by implication of law without any express agreement. A lien might also be created by a contract or agreement between debtor and creditor by which the debtor deposited personal property with the creditor as security for his debt (see PLEDGE), or in a particular business or trade by a usage so extensive and well established that the courts of law will recognize it. In general, a lien cannot be acquired against the owner of a chattel when possession is given to the would-be lienor by one wrongfully having possession of the chattel. Innkeepers may, however, acquire a lien on stolen goods brought to them by the thief and it has been held in England that a common carrier has a lien for freight on goods shipped by one not the owner. Possession of the property by the lienor is essential to a common-law lien; for as soon as the goods are voluntarily parted with by him the lien is gone. The lienor's only right at common law was to retain possession of the property until his claim was paid. He could not make use of it for his own purposes or sell or otherwise dispose of it without forfeiting his lien and entitling the owner to recover the value of the property in an action of trover. Equity, however, early took jurisdiction to relieve the lienor by allowing him to foreclose his lien and collect the amount due from the proceeds of the judicial sale of the chattels. In many states the lienor now has statutory authority to sell chattels on which he has a lien (usually only on notice to the owner) and apply the proceeds to the payment of the debt.

A common-law lien may be either general or specific. It is *general* when it may be enforced for a general balance due from the owner to the lienor and is not confined to the amount due upon or on account of the specific article over which it exists. A *specific* lien is one over specific goods for a debt contracted in respect to them alone, as for the price of them or for some labor or services expended upon them. Thus, a vendor of goods has a special lien upon them while they remain in his possession with the price due and unpaid, after the title to them has passed to the vendee. A miller has a special lien on the flour he has ground, an artisan on the article he has repaired, etc. Warehousemen and carriers have what has been called a general-special lien—i.e., if an owner place a large quantity of goods in their custody at one time, they may retain any portion of them in their possession for their charges upon the entire quantity, but they have no lien for charges upon goods placed with them at other times. Common carriers also have a lien for charges paid by them to connecting carriers upon the goods upon which a lien is claimed as well as for their own charges. The right of stoppage in transitu—i.e., the right of a vendor to retake goods in transit before delivery to vendee in case of the insolvency of the vendee, as security for the purchase price—although originally equitable in character, is now recognized and enforced as a lien by courts of law.

2. Equitable liens, or those enforced by a court of equity only, are in the nature of constructive trusts (see Trust); i.e., the owner of property is compelled to apply his property in certain cases specifically to the payment of his debt. Equitable liens, unlike common-law liens, may be either upon real or personal property and do not depend on the possession of the lienor. Equitable, like common-law, liens may arise by implication of law. Thus, the vendor of real estate who has given a deed of the property to the vendee has a lien to secure the payment of the purchase price; and the vendee who has paid the purchase price without securing a deed has a lien upon the land to secure the money so paid. Of like character are the reciprocal liens of partners upon the partnership property, and the lien of *lis pendens* (q.v.). Equitable liens arise more frequently from contract or agreement. An agreement for a lien or security which falls short of a legal mortgage or pledge will be enforced in equity as between the parties and against third parties who are not innocent purchasers for value. The rights of third parties with reference to equitable liens are now variously affected by statutes providing for the recording of liens and mortgages. See Recording Acts.

3. Liens in admiralty are similar to those in equity. Like the latter, they do not depend upon possession. They are enforced by means of a libel filed in the admiralty court upon the vessel or property upon which the lien is claimed. See Admiralty Law; Maritime Law.

4. Important liens also exist by virtue of statutes. One of the most beneficent of these is the lien given to mechanics and materialmen for work and material furnished for the erection of buildings, another is the judgment lien upon real property, and still another the lien given to boarding-house keepers on the goods of their boarders for the amount of board furnished and unpaid for. Most statutory liens are acquired by filing a notice of the lien in the appropriate office for records, usually the office of the county clerk; and they are enforced by judicial proceedings corresponding to foreclosure of mortgage.

LIENHARD, lēn'härt, Friedrich (Fritz) (1865–). A German poet and journalist. He was born in Rothbach in Alsace, the eldest son of a village schoolmaster, studied philology and theology at Strassburg and Berlin, spent two years as a private tutor, and then traveled in Norway, Scotland, France, and Italy. Upon his return he settled in Berlin and did editorial work for the *Deutsche Zeitung* and also for the *XX. Jahrhundert*. In 1903 he gave up journalism to devote himself entirely to independent literary work. He was one of the first disciples of the movement known as the *Heimattheorie* in art, a theory of home art as opposed to the exotic, an old idea revived in new form by Julius Langbehn's strange and at that time much discussed book *Rembrandt als Erzieher: Von einem Deutschen* (1890; 42 eds. in three years). Lienhard's lyrics, perhaps his best work, appearing as *Lieder eines Elsässers* (1895; 2d ed., 1897) and *Gesammelte Gedichte* (1902; 2d ed., 1906), have a healthy, genuine, thoroughly German tone, but fail to rise to great heights. His dramas, which for the most part are efforts to revive in form and matter old German themes (somewhat in the manner of Richard Wagner), have earnestness and dignity but little genuine life. The best are: *König Arthur* (1899); *Heinrich von Ofterdingen* (1903; 3d ed., 1911); *Wieland der Schmied* (1905; 2d ed., 1910). Of his prose works the most important is the series of six volumes of essays, entitled *Wege nach Weimar* (1904 et seq.). These appeared as a monthly publication. Among his later works may be mentioned: *Oberlin* (1910; 13th ed., 1912), a novel; *Lichtland* (1912), poems; *Der Spielmann* (1913). Consult Friedrich Kummer, in *Deutsche Literaturgeschichte des 19. Jahrhunderts* (Dresden, 1909).

LIENHARD UND GERTRUD, lēn'härt ụnt gĕr'trōōt, Ein Buch für das Volk. An educational novel, published by Johann Heinrich Pestalozzi (q.v.) in 1781, embodying his main educational ideas.

LIER, lēr, Adolf (1826–82). A German painter, born at Herrnhut, Saxony. He studied architecture in Dresden, then painting at Basel under Süffert and at Munich under Zimmermann. Afterward he was with Jules Dupré in Paris for a year and at Isle-Adam. In 1865 he went to London. Upon his return he taught at Munich from 1869 to 1873 and became the head of a school of landscape painters which, like the Barbizon school, expressed the moods of nature rather than her physical aspects and has had considerable influence on German art. His subjects are usually storms or evening effects, painted in the neighborhood of Munich or in France, with much simplicity and intimate charm. Among the best known are: "The Oise by Moonlight" (1867, Dresden Gallery); "Evening on the Isar" (1877, National Gallery, Berlin); "Harvest in Upper Bavaria" (Leipzig Museum); and "Scottish Coast Landscape" (Stuttgart Museum).

LIER, Jacques van (1875–). A celebrated Dutch cellist, born at The Hague. He began his studies in his native city under Hartog and Giese and later went to Eberle in Rotterdam. In 1891 he became first cellist of the Palace Orchestra of Amsterdam. The following year he took up his residence in Basel, whence he made several extensive concert tours through Europe. From 1897 to 1899 he was a member of the Berlin Philharmonic Orchestra and in the latter year joined the faculty of the Klindworth-Scharwenka Conservatory. Together with Bos and Van Veen he formed the Dutch Trio, and with Van Veen, Feltzer, and Ruinen the Dutch String Quartet, both of which organizations enjoy a European reputation. He is the author of a number of instructive works for the cello.

LIERNE (lyârn) **RIB** (Fr., perhaps for *lienne*, warp thread uncrossed by the woof, from *lier*, from Lat. *ligare*, to bind). A minor rib in Gothic vaulting. The name is properly applied to the short ribs which connect the main ribs sprung from the vaulting shaft with each other and with the ridge rib, forming more or less elaborate patterns. The vaulting in which they are used is called lierne vaulting, which in England preceded fan vaulting (q.v.); in France it occurs but rarely, and it is found in modified form in Spain and Germany.

LIERRE, lyâr (Flem. *Lier*). A town of Belgium, in the Province of Antwerp, 9 miles southeast of the city of Antwerp, at the confluence of the Great and Little Nethe (Map: Belgium, C 3). Its church of St. Gommarius, a fine late Gothic building, finished in 1557, has three fine windows, donated by the Archduke Maximilian, and a number of excellent paintings, including two by Rubens. Lierre manufactures silk, lace, sugar, shoes, and beer. Pop., 1900, 22,654; 1905, 24,611; 1910, 25,869. Lierre was bombarded several times by the Germans in the severe fighting which preceded the fall of Antwerp during the European War which began in 1914. See WAR IN EUROPE.

LIES, FIELD OF. See FIELD OF LIES.

LIESIN, lē′zĭn, ABRAHAM (1872–). The pen name of Abraham Walt, a Jewish-American poet and journalist. Born in Minsk, Russia, of orthodox parents, he received the traditional Jewish education. His heretical views, however, led to his expulsion from the Volozin Talmudical College, and he went to Vilna, where he soon plunged into the revolutionary movement. In 1896, dissatisfied with the existing revolutionary organization, he formed a new one (called simply the Opposition), which already had a strong following when its founder, who had long been hounded by the secret police, was obliged to leave Russia. He came to New York in 1897 and resumed his Socialist-revolutionary activity. His articles appeared in every prominent Jewish-Socialist organ and played a great part in the development of Jewish-American Socialism. In 1914 he became editor of *Die Zuknuft*, a Yiddish-Socialist monthly. His verse, the first of which appeared in 1893, includes lyrics and miscellaneous poems. The former show the unmistakable influence of Heine and rank very high in contemporary Yiddish poetry, while the latter include some of the choicest romantic ballads in the Jewish language. Less impressive, though numerous, are his libertarian poems, specimens of which may be found in a miscellaneous volume of verse, culled from the work of various Yiddish contemporary poets, entitled *Freiheit: Revolutionäre Lieder* (Geneva, 1905).

LIESKOV, lyĕ-skôf′, NIKOLAI SEMIONOVITCH (1831–95). A Russian novelist, known at one time under the pseudonym of Stebnitsky. He was born in the Government of Orel, and though early thrown upon his own resources, becoming a court clerk at 17, he managed to round out his education. He not only read much, but, as secretary of a circuit court, traveled considerably. It was during these years of wandering that he gathered an almost inexhaustible wealth of literary material. His career as a writer began with a few striking sketches in 1860. Having incurred the bitter censure of radicals by his reactionary attitude, he went abroad before publishing his first novel, *No Way Out* (1864). Its uncomplimentary pictures of Nihilists and its general disparagement of contemporary Nihilism further incensed the radicals. Yet the author's second work, *To the Knife* (published serially in 1870–71), proved even more objectionable to the social idealists. Afterward, however, his work gradually lost its polemical character and became more popular. *The Priests* (1872) clearly marked this turning point. With his next collection of stories, *The Sanctified* (1881), his name and fame rapidly spread. He even received an important appointment in the Ministry of Public Instruction, which, however, he relinquished in 1883. Then, coming under the influence of Tolstoy's moral philosophy, he studied the history of Christianity and took to writing religious legends in the style of Flaubert.

Lieskov's inventive fertility is amazing; his shortest stories (of five or six pages) could easily be expanded into long novels. His literary form is equally compressed. Finally, his art in conveying local color and his extraordinary mastery of language place him among the great Russian novelists. The latest complete edition of his works (13 vols., St. Petersburg, 1902–03) contains a good biographical and critical study of the author.

LIEUTENANT, lů-tĕn′ant, *or, esp. Brit.*, lĕf-tĕn′ant (OF., Fr. *lieutenant*, It. *luogotenente*, from ML. *locum tenens*, one who holds another's place, from Lat. *locus*, place, and *tenere*, to hold). A subaltern military rank. In the United States a military cadet on appointment to the army receives the grade of second lieutenant, becoming first lieutenant in the order of seniority as vacancies occur. In the British service second lieutenants are appointed lieutenants in their regiments or corps as vacancies occur. The number of lieutenants per company varies in many European armies, but the general average is two or three to each captain or company. The duties of a lieutenant the world over are to assist the captain under whom he serves and to supervise the routine details connected with the interior economy of his corps or regiment, as officer of the guard, officer of the day, etc. On active service he would usually have command of examining guards, patrols, and pickets. In the United States army it frequently happens that, owing to the scattered posts and detachments, the first lieutenant is virtually the company commander and exercises all the functions and performs all the duties incident to the rank of captain. See PAY AND ALLOWANCES.

Lieutenant, Naval. A lieutenant in the navy is an officer junior in rank to a lieutenant commander and senior to an ensign. Lieutenants are of two grades, senior and junior. The senior ranks with a captain in the army or marine corps and the junior with a first lieutenant in either of these services. Lieutenants perform duty as watch officers, senior engineers, first lieutenants, navigators, executive officers, ordnance officers, or division officers depending upon the size of the vessel and other circumstances. The pay of lieutenants of the senior grade is $2400 and of the junior grade $2000 per annum; to these amounts there is an addition of 10 per cent for each five years of service. The number of lieutenants on the active list of the navy on Jan. 1, 1915, were, senior grade, 351; junior grade, 381.

Lieutenant, First, of a man-of-war. Formerly the officer of the line or executive branch next in rank to the captain was a lieutenant, and to distinguish him from the others of the same rank he was called the first lieutenant, and he performed the duties of executive officer (q.v.). During the Civil War the grade of lieutenant commander was instituted. For many years afterward an officer assigned to duty as executive officer continued to be referred to as the first lieutenant, even if his actual rank was that of lieutenant commander. The arduous duties of the executive officer increased as the size of ships was augmented, until it was realized that in battleships and armored cruisers of modern type the work was too great for one man. It was therefore divided, and that portion concerning the care and maintenance of the *matériel* of the ship assigned to an officer who is designated the *first lieutenant*. He is usually next in rank to the executive, though this is not the invariable practice; but he is always senior to all divisional officers. In rank he may be a lieutenant or a lieutenant commander. See Rank and Command.

LIEUTENANT COLONEL. The intermediate rank between major and colonel. In the United States army his duties are to assist the colonel in command of the regiment. In the United States army a lieutenant colonel may command a battalion when the major is absent. In European armies the lieutenant colonel is often the actual commander of the regiment, the title of colonel being an honorary one conferred upon royal and other important personages. See Pay and Allowances.

LIEUTENANT COMMANDER. An officer of the United States navy above the rank of lieutenant and below that of commander. The grade was established upon the reorganization of the navy in 1862. Lieutenant commanders rank with majors in the army and have the same pay. A lieutenant commander may command a ship of the fourth rate or a ship not rated, or serve as executive officer, first lieutenant, navigator, or senior engineer officer in a ship commanded by an officer of a superior grade. On shore he performs such duties as may be assigned him. The number on the active list of the navy in 1915 was 204.

LIEUTENANT GENERAL (United States army). According to the Act of May 28, 1798, the President is authorized to appoint, by consent of the Senate, a commander of the army. It is provided that the commander of the army, as well as other officers appointed under the act, may be discharged whenever in the opinion of the President the public safety justifies it. Originally the commander was commissioned as lieutenant general, but on March 3, 1799, it was enacted that this rank be abolished, and the title of general substituted. On Feb. 15, 1855, the grade of lieutenant general was revived for Major General Scott for his services in the Mexican War. He retired in 1861. In February, 1864, an Act of Congress was passed directing that the grade of lieutenant general be again revived. On March 2, 1864, Maj. Gen. U. S. Grant received the appointment, followed on July 25, 1866, by Maj. Gen. W. T. Sherman, the grade of general having been revived for Lieutenant General Grant. When the latter was elected President of the United States, Lieutenant General Sherman was made general, Maj. Gen. P. H. Sheridan becoming lieutenant general. An Act of Congress, 1870, abolished the office of lieutenant general and general as soon as vacated. The grade was revived for Major General Schofield from Feb. 5 to Sept. 29, 1895, and again for Major General Miles in 1900. Since the retirement of Lieutenant General Miles as commanding general of the army, the office of lieutenant general and chief of staff has been held by Generals Young, Bates, and Chaffee. The grade expired with the death of Lieut. Gen. Arthur MacArthur. A field army, composed of two or more divisions, is the appropriate command of a lieutenant general. In the United States army the grade does not exist in time of peace, but may be revived in time of war.

LIEVELY. See Godhavn.

LIEVEN, lē′vĕn, Dorothea, Princess of (1784–1857). A woman once prominent in the diplomatic circles of Europe, the daughter of Christoph von Benkendorf, an Esthonian of the middle class. She was born at Riga and received a brilliant education. She was married in 1800 to Prince Christoph Lieven, Russian Ambassador to Prussia, displayed remarkable diplomatic aptitude, and soon enjoyed a continental reputation. On her husband's appointment to the Court of St. James's in 1812, she speedily established herself in a firm position in the political and fashionable society of London. In 1837, upon the death of her husband, she removed to Paris. Here her salon was the centre of schemes and intrigue involving the interests of half of Europe. Consult L. G. Robinson, *Letters of Dorothea during her Residence in London, 1812–1837* (London, 1902), and Sir Spenser Walpole, *Essays, Political and Biographical* (New York. 1908).

LIEVENS, lē′vĕns, **LIVENS,** or **LIEVENSZ,** Jan (1607–74). A Dutch historical and portrait painter and etcher, born at Leyden. He studied at an early age under Joris van Schooten, and later with Peter Lastman at Amsterdam. His work became known in England through the Prince of Orange, and Charles I invited him to visit his court. After a stay of three years in England he settled at Antwerp, where he entered the painters' guild in 1634, and in 1643 he removed to Amsterdam. His early work shows strong resemblance to that of his great contemporary Rembrandt, although inferior in draftsmanship, color, and invention. Many works attributed to the greater master, like the "Presentation in the Temple" in The Hague Museum, are supposed by some critics to be the joint work of both, while others, such as "St. Paul in Meditation" (Museum of Art History, Vienna), are entirely by the hand of Lievens. His work has also been confounded with that of Van Dyck, who strongly influenced his later style. Lievens helped to introduce Caravaggio's influence into Dutch monumental art. Among his authentic paintings are: "Abraham Embracing Isaac" (1642) (Brunswick Museum); "Samson and Delilah" (Amsterdam Museum); portrait of Sir Robert Ker (Newbattle Abbey, Edinburgh). As an etcher, he takes a high rank; his plates are somewhat in the manner of Rembrandt.

LIEZEN-MAYER, lē′tsen-mī′ĕr, Alexander von (1839–98). An Hungarian painter and illustrator. He was born at Raab and studied at Vienna and Munich, where he became the pupil of Piloty in 1862. He first attracted attention with two episodes from the history of his native land, "Queens Mary and Elizabeth of Hungary at the Tomb of Louis the Great" and "Coronation of Charles of Durazzo." Three years afterward he was commissioned by the academy to paint "Canonization of Elizabeth of

Thuringia"; and signal success came to him in 1867 with the completion of his "Maria Theresa Nursing a Poor Woman's Child." Among his best works at this time were his portraits, which include those of the Bishop of Raab, Alexander Wagner, and Emperor Francis Joseph, painted at Vienna in 1870. After his return to Munich he painted, among other historical compositions, "Elizabeth Signing the Death Warrant of Mary Stuart" (1873), now in the Museum at Cologne; "St. Elizabeth of Hungary Performing an Act of Charity" (Budapest Museum); and "Matthias Hunyadi Receives the News of his Elevation to the Throne" (1897)—his last painting, which received the great gold medal at the Budapest Millennium Exhibition. Liezen-Mayer was one of the most talented followers of Piloty (q.v.), and to those traditions he remained faithful throughout his career. That he was a draftsman of the first rank is proved by his illustrations for Goethe's *Faust* (50 cartoons) and Schiller's *Lay of the Bell* (32), done between 1874 and 1880. He was appointed director of the School of Art at Stuttgart in 1880, but returned to Munich in 1883 and in the same year was made professor at the academy.

LIFE, MEAN DURATION OF. The average length of life enjoyed by a given number of persons of the same age. Of 100,000 persons aged 10 years, 749 die the first year. Of the remainder, 746 die in the next year. Following up the deaths each year until all die, it is ascertained that the average age to which a number of the group of 100,000 survives is 48.7 years. This is called, in other words, one's "expectation of life." Though many die sooner, a boy of 10 years may expect to live to be 48.7 years old. If he survives to that age, his expectation at 59 years is that he will live 14.7 years longer, as that is the average age reached by the 59,385 survivors of the original group of 100,000 who attain the age of 59.

Following is an Expectation Table constructed for the use of insurance companies from the American Table of Mortality, which has been adopted by the State of New York as the standard for valuation of insurance policies:

COMPLETED AGE	Number surviving at each age	Deaths in each year
10	100,000	749
11	99,251	746
12	98,505	743
13	97,762	740
14	97,022	737
15	96,285	735
16	95,550	732
17	94,818	729
18	94,089	727
19	93,362	725
20	92,637	723

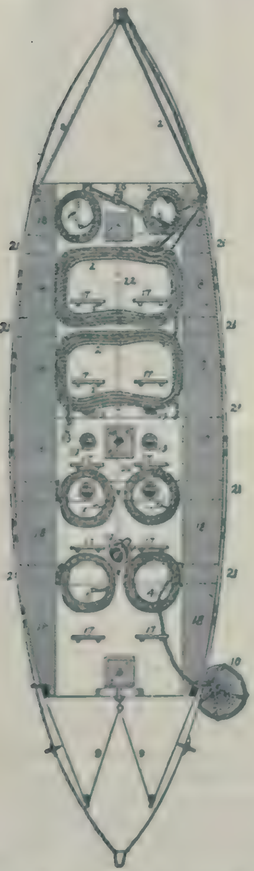
89	1,402	555
90	847	385
91	462	246
92	216	137
93	79	58
94	21	18
95	3	3

According to the Actuaries' or Combined Experience Table of Mortality, as given by Greene, the number of deaths in each year is somewhat lower. At 10 years, e.g., of 100,000 individuals the number dying is 676, with an expectation of 48.7 years. At 20 years the number of deaths would be 680, with a life expectation of 41.49 years. See Brandreth Symonds, *Life Insurance Examinations* (New York, 1905); C. L. Greene, *The Medical Examination for Life Insurance* (Philadelphia, 1905).

LIFE AND ADVENT UNION. See ADVENTISTS.

LIFEBOAT. A boat specially constructed for saving persons from wrecked or imperiled vessels, in storms or heavy seas, when the use of an ordinary open boat would be impossible or extremely dangerous. There have been countless contrivances for this purpose, all varying in their types; but unless a boat is provided with some distinctive properties, such as those of self-bailing or self-righting, or both combined, it is not considered a lifeboat in the strict meaning of the term. The conventional open boat, with or without air chambers, which is used in broken water along the seashore for rescuing life, is known as a surfboat. The name "surfboat" is generally applied to boats which are designed to be launched from the beach without the aid of launchways, etc. Surfboats are principally used by the coast fishermen for passing daily out and in through the surf in pursuit of their vocation.

The many so-called improvements that have been devised at one time or another for lifeboats, which have modified or departed from first principles, have generally proved of no practical value, and there would be little advantage in considering them here. Neither would it serve any profitable purpose to go further back than the time of the origin of the present English model, even if that could be done with any degree of certainty. In 1785 Lionel Lukin, a coach maker of an inland town near London, put afloat on the Thames a Norway yawl, which he had fitted with water-tight compartments, a heavy iron keel, and other essentials in buoyancy and stability, which are the cardinal and requisite features of the lifeboat of to-day. Lukin did not succeed in bringing his invention, which had many defects, into particular notice up to the time of his death, which occurred in 1834. An expert boat builder of South Shields, Henry Greathead, however, put Lukin's device into practical use as early as 1790, when he produced a boat embodying the elements of the original, but with a curved keel and the substitution of cork for side air chambers. This boat had no means of freeing itself of water or of self-righting in case of being capsized. James Beeching, of Great Yarmouth, was really the first person to project a self-righting lifeboat, which he did in 1851, the design subsequently being bettered by James Peake, who added to it the self-bailing quality. This boat has since been much improved by study and experiment.



DECK PLAN OF A SELF-RIGHTING LIFEBOAT, SHOWING THE MANNER IN WHICH THE GEAR IS STOWED.

List of articles shown: 1, anchor; 2, cable; 3, bow heaving line or grapnel rope and grapnel; 4, drogue rope; 5, stern heaving line; 6 and 7, veering lines; 8, jib outhaul or tack; 9, mizzen sheets; 10, drogue; 11, life buoy; 12, loaded cane, heaving line and tub; 13, tailed block; 14, pump-well hatch; 15 and 16, deck ventilating hatches; 17, footboards for rowers; 18, side air cases; 19, relieving tubes and valves; 20, Samson post; 21, thwarts; 22, central batten, to which the masts and boat hooks are lashed.

The chief requirement of the English lifeboat is to counteract, as far as practicable, the tendency of the boat to swamp when it ships a sea and to remain bottom up when capsized. It therefore must possess extra buoyancy, stability, self-bailing and self-righting qualities.

Thirty-four-foot lifeboats patterned after the English model were formerly used in the United States Life-Saving Service at stations on the Great Lakes and at a few points on the ocean coasts where they could be launched. In the process of development of an efficient power lifeboat, 25-horse-power gasoline engines were installed in the 34-foot boats, and these converted boats have been in turn superseded by larger and better power lifeboats. The power lifeboat in the United States Life-Saving Service is 36 feet long, has an extreme width of 8 feet, 7½ inches, and develops a uniform speed of about 9 miles an hour. For motive power the boat is provided with a gasoline engine, sails, and oars for use in case of necessity. The motor is a 6-cylinder, 4-cycle, 35–40-horse-power automarine engine. It is placed in the after-end air chamber of the boat, and on the outside of the bulkhead, in recesses, are starting crank shaft, reverse lever, oil cups, etc. The boat is electrically lighted and is provided with a knockdown guard rail and a folding spray hood. None of the characteristic features of a lifeboat, such as self-righting and self-bailing, is in any way impaired by the installation of the engine and its accessories. In the event of a capsize the engine stops automatically and, owing to its inclosure in the water-tight compartment, suffers no damage or derangement. This type of boat weighs about 8½ tons and is launched from launching ways or by the use of hoisting apparatus. The frames of the boat are of white oak, and the outside planking is of Honduras mahogany, laid diagonally. To render the craft buoyant and insubmergible, a large air-tight compartment is built at each end (the engine is in the stern compartment), and air cases are placed under the deck and along the sides of the boat abovedeck and beneath the thwarts. The self-bailing of the lifeboat is accomplished by means of 10 draining tubes, 7 inches in diameter, extending from the deck, above the water level, down through the bottom of the boat, the top of each tube being fitted with a self-acting valve, which opens downward when there is pressure from above and permits the water to flow out, but prevents it from entering the boat from below. Should the boat capsize and right itself filled with water, or be boarded by heavy seas, the water passes through the valves into the relieving tubes and escapes. A heavy gun-metal keel is secured to the wooden keel of the boat, and this, in conjunction with the air chambers, effects the self-righting property. The craft, when bottom up, floats unsteadily on the bow and stern compartments, while the keel, being carried above the centre of gravity, falls on one side or the other and drags the boat back to its natural, upright position, the water that has been shipped in the process passing out through the tubes. The lifeboat has five thwarts, which can accommodate 10 oarsmen, double banked, is fitted with a centreboard, and provided with movable masts. Suspended below the gunwales along each side of the boat are festooned life lines, to which persons in the water may cling until they can be helped into the boat. The equipments, which are very complete, are carefully stowed in the boat always ready for im-

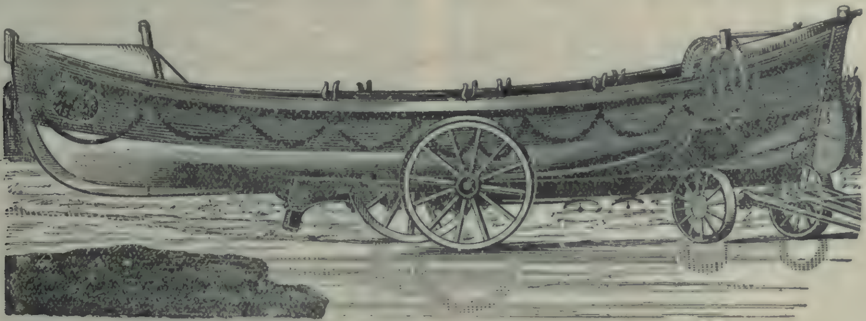
mediate service. The installation of motive power in the lifeboats has greatly extended the field of operations of the service by enabling the crews to cover long distances to scenes of disaster where otherwise assistance could not be had.

The American lifeboat, extensively used on the ocean and lake coasts of the United States by the Life-Saving Service, known as the Beebe-McLellan self-bailing surfboat, is entitled to rank next to the lifeboat above described in exceptional qualities, and in some respects it is superior to it in all-around work. The makers have applied the self-bailing principle to a convenient surfboat of light weight, about 1000 pounds, which can be transported and launched almost anywhere with ease and celerity, and whose liability to capsize is greatly diminished by reason of its ability quickly to free itself of water. It is a cedar, clinker-built boat, 26 feet long, about 7 feet in breadth, with 4 thwarts, a centreboard or none, as desired, and is fitted with air tanks and delivery tubes. Its light weight, as compared with the cumbersome English lifeboat, is of material advantage to boatmen in American waters, while the self-bailing feature gives confidence to those who handle the craft in rough surf where the chief danger lies in being swamped by a boarding sea. The boat is rigged with righting lines, to be used in case of an upset, and is otherwise equipped for all emergencies. It can be carried on shipboard with little trouble.



ENGLISH LIFEBOAT.

The introduction of motor power into this boat has given additional support to the claim of high rank for the American boat. This self-bailing power surfboat is the first and probably the best power surfboat used in any life-saving service and is fast displacing the oar-propelled self-bailing surfboat herein described. The weight of the engine, which is in the centre of the boat and as low as possible, adds to the stability of the boat. The engine is a 12-horsepower, 2-cycle, 3-cylinder horizontal motor, inclosed in a water-tight compartment. The eight oars carried are chiefly used for launching and landing through the surf and for manœuvring about wrecked vessels. There are two 15-inch propellers, one on each side of the stern of the boat, which, by means of a lifting and lowering device, may be drawn up close to the planking so that the propellers will not be injured during launching and landing. This type of boat weighs about 3000 pounds and is not too heavy to be transported along the beach on a boat wagon from which it can be lowered to the water with comparative ease. The introduction of motive power in this boat makes it possible for the boat's crew to arrive on the scene of disaster more quickly and with strength and efficiency unimpaired by the extreme exertion of rowing.

There are many other types of boats designed for saving life, the greater number being for use on merchant ships. The characteristics deemed most essential in these are lightness, buoyancy, and seaworthiness. What is known as the New England whaleboat, long, rather narrow, sharp at both ends, and steered with an oar, is much favored by seamen. Collapsible boats of various patterns, which occupy little space when not in use, are likewise employed, as well as ordinary metallic boats, the latter being less liable to injury when exposed to undue heat and moisture. Methley, *The Life-Boat and its Story* (London, 1912). See LIFE-SAVING SERVICE; SAFETY AT SEA; and kindred articles.

LIFE BUOY. A float intended to support persons who have fallen into the water until other assistance can reach them. Those in common use are large rings of cork-stuffed canvas, each about 30 inches in diameter with a life line looped to the outer side. The wearer gets within the ring, with his arms thereon, and is sustained. These buoys are usually kept at convenient places on shipboard, wharves, etc., where they may be readily detached and thrown to any one in danger of drowning. More elaborate buoys of the circular type, used in the navy and merchant marine, are fitted with markers, so that they may be easily seen when afloat, or with lights which ignite upon contact with the water or by an automatic device as they are released from their places. Life buoys are also constructed of rubber tubing, inflated; but these are liable to damage by being punctured or torn, or are apt to decay prematurely. A buoy, with an opening in the ring, shaped like a horseshoe, has been found to answer its purpose very well. See LIFE-SAVING SERVICE.

LIFE ESTATE. In the common-law system of England and the United States, an estate in land for the life of the tenant or of another. In quality the life estate is a freehold, and therefore of more importance than any leasehold, however long; but in point of quantity or duration it is rated as inferior to the freeholds of inheritance, viz., the fee simple and the fee tail. Historically considered, however, it is of more importance than any of these, being the original form of the fee, or feud, and the most characteristic form of feudal tenure of land. See Fee.

The ordinary classification divides life estates into the "conventional," or such as arise by agreement (*conventio*), and the "legal," or such as arise by operation of law. The ordinary life estate, created at common law by livery of seisin and to-day by deed or will, belongs to the former class. The latter includes the matrimonial estates, curtesy, and dower (qq.v.), and a form of fee-tail estate which is no longer capable of inheritance, technically called "fee tail after possibility of issue extinct." But, however created, the qualities and incidents of life estates are the same. They come to an end abruptly on the termination of the life or lives by which they are measured, leaving no interest to descend to the heir of the life tenant or to pass to his devisees under his will. Being in quantity or duration less than the fee out of which (as the expression is) they are "carved," the land does not, upon the termination of the life estate, go to the state by escheat, but returns to the holder of the fee simple as a reversion or remainder (qq.v.). Though a freeholder, the tenant for life is liable for waste committed or "suffered" by him on the premises and is subject to an obligation of fidelity to his landlord, the reversioner, or to the remainderman. A breach of this obligation, as by making a wrongful conveyance of the premises in fee simple by feoffment, involved a forfeiture of the life estate to the injured landlord. This characteristic of the estate has disappeared with the abolition of feoffment and other "tortious conveyances." See Feoffment; Forfeiture; Waste.

Subject to his liability for waste, the life tenant has most of the rights of an owner of the land. He might at common law protect his possession by the same ancient and exclusive remedies as were available to the tenant in fee simple. His estate is regarded as real property, and not, like a leasehold, however long, as personal estate. He is entitled to estovers (i.e., wood for fuel and repairs, and the like), and his personal representatives are, after his death, entitled to the emblements, or growing crops. (See Emblements; Estover.) He may, by the methods appropriate for the conveyance of freeholds (livery of seisin, deed), freely alienate his estate, though he cannot in general give an estate to endure beyond his own. It is not uncommon, however, in creating a life estate, to confer upon the life tenant a power to lease the premises for 21 years or other determinate period, and a lease so made holds good notwithstanding the prior termination of the life estate. In England, where life estates are frequently created as an incident of marriage settlements for providing a revenue for the parties to the marriage and their issue, it has been provided by statute that such a life tenant may make long leases not subject to the life estate. (Settled Land Acts, 1882, 1890.)

An estate for the life of another than the tenant himself (still known by its Norman-French description as an estate *pur auter vie*) may arise either directly, as by a grant of land to A for the life of B, or indirectly through a conveyance by a life tenant of his life estate to another. In neither of these cases does the estate come to an end upon the death of the tenant *pur auter vie*, the person by whose life the estate is measured (known as the *cestui que vie*) being still alive. In that case there is an unexpired fragment of the life estate remaining, which, at the common law, vested in the first person to take possession thereof (known as the "general occupant") or in a person designated by the creator or the tenant of the life estate (known as the "special occupant"). This remnant of an estate *pur auter vie* is now generally disposed of by statute, going either to the heir or to the personal representative of the life tenant. See Occupancy. See also Estate; Fee; Tenure; and authorities referred to under Real Property.

LIFE FOR THE CZAR, The. The first national Russian opera, by Glinka (q.v.), first produced in St. Petersburg, Dec. 9, 1836.

LIFE GUARDS. The First and Second Regiments of Life Guards are cavalry regiments of the British Household Cavalry and are stationed at Windsor and Regent's Park, London, respectively. They are the senior regiments of the Household Brigade and, being the personal regiments of the sovereign, are not required to go on foreign service. This rule, however, has been broken in every great campaign in which since their organization England has been engaged; notably at Dettingen, in the Peninsular campaign, Waterloo, Tell el-Kebir, in South Africa, and in the European War of 1914. In this latter conflict the Fourth Cavalry Brigade had a composite regiment, made up of detachments of the Household Cavalry. They had their origin in 1660, being then composed of the cavaliers forming a bodyguard for Charles II. Subsequently two troops of horse grenadiers, raised respectively in 1693 and 1702, were reorganized in 1783 as regiments of life guards. They are armed with sword and carbine, mounted on heavy black chargers, and wear a dress uniform consisting of white leather breeches, knee boots, red coat, steel helmet and cuirass, the former surmounted by a high plume. The rank and file are required to be over 6 feet in height before enlistment. Each regiment carries four standards, their motto being *Dieu et mon Droit*. In time of peace they are more or less occupied in the performance of duties about the court and metropolis.

LIFE INSURANCE. Life insurance is a term used to cover a variety of transactions in all of which the uncertainty of human life plays a more or less important part. In its purest form a life-insurance contract contains an agreement on the part of the insurer to pay a stated sum upon the death of the insured, if that event occurs while the policy is in force. In recent years, however, the investment principle has come to be quite as prominent in life underwriting as the insurance principle, and through the combination of the two principles there has developed the great variety of policies now written by life-insurance companies.

History. Originally life insurance was not much more than an incident of marine insurance. When the success or failure of a voyage depended largely on the personal qualities of the master of the ship, the owners of ship and cargo would insure themselves not only against the perils of the deep, but also against the danger of loss through the death of the master; that is, they took out insurance on the life of the master for the voyage. These early life-insurance policies were written by individuals long before life-insurance companies came into existence. The earliest policy of which anything definite is known was issued in London in 1583, insuring the life of one William Gybbons for 12 months. This was underwritten by 13 persons acting individually; the premium was $80 per thousand. A similar policy would cost to-day about $10, at age 35.

The earliest life-insurance company of which we have definite information was established in 1699 by the Mercers' Company of London for the benefit of the widows and orphans of subscribers. The business of the company was limited to annuities, but rates were inadequate and it soon failed to fulfill its obligations. The oldest existing life-insurance companies are the London Assurance Corporation and the Royal Exchange Assurance Corporation, both of which were chartered in 1720 and began to issue life policies in 1721. Life insurance, however, was at first but a minor feature of their business, nominal in amount and limited to short-term contracts. The Equitable, established in 1762, was the first office to devote itself exclusively to the business of life insurance and to make use of the scientific methods which characterize modern underwriting. The only other surviving English society which came down from the eighteenth century was the Pelican, which was founded in 1797, and was recently combined with the Empire, both being now merged in the Phœnix.

LIFE INSURANCE IN THE UNITED STATES

YEAR	No. of companies	No. of policies	Insurance in force	Assets	Surplus
1880	30	608,681	$1,475,995,172	$417,951,009	$71,561,669
1885	29	814,691	2,023,517,488	523,664,678	92,749,486
1890	30	1,272,895	3,542,965,751	753,228,759	* 88,739,362
1895 †	35	1,877,808	4,818,170,945	1,142,419,926	159,750,174
1900	40	3,071,253	6,947,096,609	1,723,737,723	158,277,942
1905	43	5,306,161	10,553,839,955	2,651,316,714	‡ 362,357,798

1913	34	7,452,154	14,304,638,791	4,417,298,211	256,936,224

* The apparent decrease of surplus in 1890 was due to the change from the American Experience Table at 4½ per cent interest to the Actuaries' Table with 4 per cent interest. That of 1910 is due to several circumstances, among them the change of base of valuation to 3 per cent, the rapid payment of maturing deferred dividends, the temporary decline of market values of securities, and the withdrawal of a number of outside companies on account of the newly enacted restrictions of the New York insurance law.

† In 1895 and later years assets and surplus of companies transacting principally or solely industrial insurance appear in the table. Number of policies and amount of insurance in force are exclusive of industrial insurance.

‡ The extraordinary increase in surplus in 1905 was due to including items not included before 1901.

The Presbyterian Ministers Fund Life Insurance Company of Philadelphia is often erroneously referred to as the "oldest company in America." It is in fact the successor of a church benevolent society which was incorporated in 1759 under the name of the "Corporation for the Relief of Poor and Distressed Presbyterian Ministers, and of the Poor and Distressed Widows and Children of Presbyterian Ministers." Its early operations were limited to the payment of annuities, but its plan was unscientific and its rates inadequate. It was not properly a life-insurance company, and the amount of business done was little more than nominal. It did not begin the issue of regular life-insurance policies until late in the nineteenth century, probably in 1875, when its charter was amended and its present name adopted. Several similar societies were incorporated in the eighteenth century, but these ceased to exist after a few years. The first general life company, the Pennsylvania Company for Insurances upon Lives and Granting Annuities, was chartered in Philadelphia in 1812. It is still doing business as a trust company, but ceased writing life insurance many years ago. In 1818 was organized the first Massachusetts company, known as the Massachusetts Hospital Life Insurance Company. This company, also, wrote but little life insurance, soon confining its business to that of a trust company. Several other companies were organized in the next 20 years, among them the New York Life Insurance and Trust Company, chartered in 1830. Like the other early companies, it soon ceased issuing life-insurance policies, but continues to sell life annuities, and is to-day one of the substantial trust companies of New York. It still has two life-insurance policies in force (September, 1914), one issued in 1859, at age 22, and the other in 1860, at age 20. It was not until in the early forties that American life insurance began to assume large proportions. In that decade some of the most prominent of existing companies were established. The Mutual Life of New York began business on Feb. 1, 1843; The New England Mutual of Boston, Feb. 1, 1844; the Mutual Benefit of Newark, N. J., April 1, 1845; the Nautilus, now the New York Life, April 12, 1845; the State Mutual of Worcester, Mass., June 1, 1845; the Connecticut Mutual of Hartford, Dec. 15, 1846; and the Penn Mutual of Philadelphia, May 25, 1847.

After the Civil War a large number of new companies entered the field and a period of intense competition followed. The resulting laxity in the inspection of risks and great expenses of management, with lack of adequate State supervision, led many of the newer and less conservative companies into financial difficulties. During the decade following 1870 a considerable number of companies failed and many others reinsured their risks and were forced to retire from business. This aroused a hitherto unknown feeling of distrust in the minds of the people and caused a falling off in the amount of business, from which some companies were 15 years or more in recovering, though others were but little retarded in their growth. The seriousness of the decline during this period is shown by the following statistics of the insurance in force in companies reporting to the New York Insurance Department: 1870, $2,023,000,000; 1875, $1,922,000,000; 1880, $1,524,000,000; 1885, $2,023,000,000. During the same years the number of companies which reported to the New York Department fell from 71 to 30. Since 1880 the growth of the business in the United States has been steady and rapid. According to the Year Book for 1914 the insurance in force in American companies on Dec. 31, 1913, amounted to $16,168,781,226. At the same time there were industrial policies in force carrying $3,906,046,899, or more than $20,000,000,000 in all.

A very large proportion of the life insurance in force in the United States is in the hands of companies making reports to the New York State Insurance Department. The extraordinary growth of the business since 1880 may be perceived from the preceding table, compiled from these reports.

Technique. The principles by which premium rates are determined in life insurance are few and simple, though the practical application of the principles involves elaborate mathematical calculations and formulæ. The attempt here is to bring out clearly the nature of the fundamental principles. Any one desiring to investigate the mathematical side of the subject will find abundant material in *The Principles and Practice of Life Insurance* (8th ed., New York, 1912).

Uncertainty in respect of the duration of a single life was from the first the chief difficulty to overcome in forecasting the probable future cost of life insurance. How long a particular individual will live cannot be known in advance; but mortality tables have been constructed from the experience of the past, which indicate approximately how many of a large number of persons, all of a given age, will die within a year; how many will live more than one year but die within two; how many will die within 10 years, 20 years, or any given number of years, until all are dead.

Mortality Tables. The discussion of the general subject of mortality tables will be found in the article on VITAL STATISTICS. We shall note only a few tables which have been in general use among life-insurance companies. The early policies were for short periods, and rates were based rather on guesswork than on any definite notion of the actual risk assumed. The premium rates were accordingly high and were independent of the age of the insured. The Amicable of England, which worked on the assessment plan, continued as late as 1807 to make uniform assessments on all ages, partially protecting itself by admitting to membership only persons between 12 and 45 inclusive. No stated sum was promised as a death benefit, but the yearly receipts, less expenses, were distributed annually among the representatives of those who had died during the year. When the more exact calculation of risks was attempted the early English companies relied chiefly on tables prepared by Halley (1693) and Süssmilch (1741). Afterward the Northampton table came into general use. This was prepared by Dr. Thomas Price from the registers kept in the parish at Northampton for the years 1735 to 1785. The Northampton table was later superseded by the Carlisle table. This was prepared by Joshua Milne about 1815 on the basis of two classes of statistics, enumerations of the population of two parishes of Carlisle in 1780 and 1787 and the records of deaths in the two parishes for the years 1779 to 1787. Although the data on which the table was based were very scanty, the total number of deaths, e.g., being only 1840, they were worked over with so much care that the results were much more accurate than those embodied in the Northampton table.

All the tables thus far referred to, as well as others of the same period, were based on the life experience of the general population. The first table which took account only of insured lives was based on the experience of the Equitable Assurance Society of London and was published in 1825. Comparatively little use has been made of this table, but a similar table, based on the combined experience of 17 English life-insurance offices and published in 1843, though never used by English companies, was formerly used by many American companies, and is still used in the calculation of reserves on certain policies issued not later than 1906. It is variously known as the Actuaries' Table, the Combined Experience Table, and the Seventeen Offices' Table. The British Offices Life Table, based on the experience of 60 British offices from 1863 to 1893, was the result of the first investigation in which account was taken of the plan of insurance. The O^{M} Table (ordinary life, participating, males) was published along with the $O^{M(5)}$ Table in 1902, and these, either alone or in combination, have gradually superseded the H^{M} Table (healthy males) for valuation purposes. At the present time (1915), practically all British offices use the new tables.

The early American offices adopted English tables, first the Northampton, later the Carlisle, and afterward the Actuaries' or Combined Experience Table. The American Experience Table was constructed by Sheppard Homans, then the actuary of the Mutual Life Insurance Company of New York, about the year 1860. It was based largely upon the experience of the Mutual Life, only lives which had been insured more than five years having been taken into consideration. The table is now used by practically all American companies, save that some companies compute the reserves of their earlier policies by the Actuaries' or Combined Experience Table and 4 per cent interest. The following tables show the number surviving at the end of 10-year periods out of 1000 living at age 10 according to the different tables mentioned above. For purposes of comparison data have been added from the mortality table recommended by the National Fraternal Congress for the use of fraternal beneficiary societies. This table starts with age 20, and not with age 10, as the other tables do. In order to make a ready comparison possible, the Fraternal Table as here given assumes 925 living at age 20.

NUMBER SURVIVING AT DIFFERENT AGES ACCORDING TO DIFFERENT MORTALITY TABLES

AGE	Northampton	Carlisle	Actuaries'	American	Fraternal
10	1,000	1,000	1,000	1,000	. . .
20	904	943	933	926	925
30	773	873	863	854	878
40	641	786	787	781	826
50	503	681	695	698	756
60	359	564	560	579	646
70	217	372	358	386	456
80	83	148	133	145	188
90	8	22	13	8	15

Inasmuch as it is impossible to forecast beyond question the exact future mortality experience of any company, we should select for use in calculating premiums a mortality table which indicates a somewhat higher death rate than well-managed companies are likely to sustain. This the American Experience Table does, but the heavy saving in mortality over this table shown by many companies accrues chiefly in the earlier years of insurance and is largely due to recent medical selection. The New York insurance law assumes that the mortality in the first year of insurance will be 50 per cent of that indicated by the American Experience Table, 65 per cent the second year, 75 per cent the third year, 85 per cent the fourth year, 95 per cent the fifth year, and that after five years the mortality will follow the table. This assumption is based upon the theory that the effect of medical selection will have disappeared after five years, no insured lives which had been examined within five years having been considered in the construction of the table. As a matter of fact, all well-managed companies do show some saving in mortality during the whole period of insurance, which is as it should be. There must inevitably be either a saving or a loss, and every consideration of safety requires the use of a table which will result in the former rather than the latter. The following figures are taken from the American Experience Table of Mortality and will serve to show the character of a mortality table. The figures from age 30 to age 90 are here condensed in order to shorten the table. Other columns are often added, such as one giving the ratio of deaths each year to the number living at the beginning of the year, and one giving the expectation of life at each age.

AMERICAN EXPERIENCE TABLE OF MORTALITY

Age	Number living	Number dying	Age	Number living	Number dying	Age	Number living	Number dying
10	100,000	749	23	90,471	720	70	38,569	2,391
11	99,251	746	24	89,751	719	75	26,237	2,476
12	98,505	743	25	89,032	718	80	14,474	2,091
13	97,762	740	26	88,314	718	85	5,485	1,292
14	97,022	737	27	87,596	718	87	3,079	933
15	96,285	735	28	86,878	718	88	2,146	744

Calculation of Premiums. As already intimated, we shall not undertake to explain here the technical methods employed by the actuary in the calculation of premiums; it is essential for the policyholder and the layman to understand merely the principles upon which the computation is based. We would point out first that the life-insurance premium consists of two parts, the *net premium* and the *loading*. The latter is for expenses and contingencies and will be explained more fully farther on. The net premium is for one purpose only—the payment of policy claims. It is vitally important to know, therefore, that the net premium is sufficient beyond a peradventure for the purpose named.

The American Experience Table of Mortality starts with 100,000 persons at the age of 10 and, according to that table, 63,364 of these will live to attain the age of 56. Adopting these figures for convenience' sake, let us suppose that we have 63,364 persons, all of the age of 56, to be insured for $1000 each on the ordinary life plan. (The ordinary life policy is the simplest form of whole-life insurance, if we except the single-premium life, which is rarely written.) The premiums on the ordinary life are to be paid annually during the remaining lifetime of the insured, and the policy is to be paid only at death. The premiums paid by these 63,364 policyholders are to constitute a common fund which, with interest, will be sufficient to pay $1000 to the beneficiary of each policyholder at death, to the last man.

Net Single Premium. To simplify the matter, let us suppose first that our 63,364 persons are to be insured for the tenth year only; i.e., all are to contribute equally to a common fund which will suffice to pay $1000 to the beneficiary of each one who dies in the tenth year, those who die before or after the tenth year to receive nothing. The mortality table indicates that 1980 of the 63,364 persons will die in that year. We know therefore that we must prepare to pay to the beneficiaries of these 1980 persons in that year the total sum of $1,980,000. Let us assume that we are to collect of each of these 63,364 persons his pro rata share of this money at once, for a good many will die before the tenth year comes. It is not necessary, however, that the entire amount of $1,980,000 be collected immediately, for the funds in our hands will earn interest during the 10 years, and we shall need therefore only the present worth of that sum. We do not know in advance what rate of interest will be earned; but, in order to be absolutely safe, we shall assume a rate so low—say 3 per cent yearly—as to make morally certain that no less will be earned. Now the sum of $1,473,305.94 at 3 per cent compound interest will amount to $1,980,000 in 10 years. It follows therefore that if our 63,364 policyholders will make up to-day a total fund of $1,473,304.94, we shall have money enough, if our funds earn 3 per cent interest, to pay the beneficiaries of all those of their number who die in the tenth year the sum of $1000 each, or a total of $1,980,000. All policyholders, being of the same age, must contribute equally to the fund. Dividing the required amount, $1,473,305.94, by the number of contributors, 63,364, we obtain the sum of $23.25. This sum, called the net single premium, is the amount which each individual member must contribute in order to provide for the deaths of the tenth year.

The mortality table shows how many of our policyholders will die in each and every year—1260 in the first year, 1325 in the second year, 1980 in the tenth year, 1292 in the thirtieth year, etc., until in the fortieth year only three, at the attained age of 95, remain to be provided for. According to the mortality table these three will die in the ensuing 12 months, requiring the payment of $3000 in the fortieth year. If, now, we can determine in the manner illustrated the sum that each one of our company must pay in order to provide for a death benefit of $1000 for all who die in the tenth year, we can as readily determine the amount that each must contribute to provide for the deaths of the first year, the eleventh year, the thirtieth year, and of every other year including the fortieth, when the last three policyholders pass away according to the table. Computing in this manner all the net single premiums that would be required for the payment of the death claims of each year, we find that the total of these net single premiums will be $621.18. That sum, therefore, is the net single premium which must be paid at once by each of the 63,364 persons in order to provide a fund sufficient, with 3 per cent compound interest, to pay all death claims as they accrue in each year thereafter according to the mortality table until the last policy matures.

Net Annual Premium. Most persons, however, would not find it convenient to pay for their life insurance in a single sum. They would generally prefer to pay a small premium each year during life—the annual premium. The *net* annual premium is found by dividing the net single premium by the value, or cost, of a life annuity of $1, the first payment of $1 to be made immediately. Such an annuity in this case would call for the immediate payment of $1 to each of our 63,364 persons, a total of $63,364. The mortality table indicates that 62,104 will be living at the beginning of the second year, requiring the payment of $62,104 at that time. In like manner, $49,341 will be required to pay $1 to each of those surviving at the beginning of the tenth year, $5,485 to pay the annuities accruing at the beginning of the thirtieth year, etc. Thus we determine the several amounts that will be required to pay the annuities of each year, including the last payment of $3 at the beginning of the fortieth year. The sum of the present worths of these several amounts, discounted at 3 per cent, will be the total fund required at the beginning to make certain the payment of a life annuity of $1 to each of the 63,364 annuitants. Dividing the total amount thus obtained by 63,364 we get $13.006, which is the net value of a life annuity of $1 at age 56.

Now if $13.006 will buy a life annuity of $1 at age 56, the sum of $621.18 (the net single premium of a whole life policy of $1000 at age 56) will buy a life annuity of as many dollars as $13.006 is contained times in $621.18. Dividing, we obtain $47.76. Inasmuch, then, as the net single premium of $621.18 will, at age 56, pay in full for a whole life policy of $1000, and inasmuch as the same sum will buy at the same age a life annuity of $47.76, it is obvious that the sum of $47.76 paid at the beginning of each year during life is the mathematical equivalent of $621.18 paid in a single sum. That is, the net single premium of $621.18 is the mathematical equivalent of a net annual premium of $47.76. Accordingly, if each of our 63,364 persons will pay the sum of $47.76 immediately, and the same sum at the beginning of each year thereafter during life, the payments will be sufficient to create and maintain a fund large enough to pay the sum of $1000 as each member dies, until the last three have passed away at the attained age of 96. Obviously the sum of $47.76 is the net annual premium required.

Limited-Payment Life. In lieu of paying premiums yearly until death, as in the case of an ordinary life policy, payment may be completed within a limited number of years, such a contract being known as a limited-payment life. A 20-payment life, e.g., calls for the payment of only 20 premiums, the policy being payable at death, as any other whole-life contract. To compute the premium of a limited-payment life policy we must first find the value of a temporary annuity—an annuity contract which terminates at the end of a stated period or at prior death. The value of a temporary annuity terminating in 20 years is computed by a process similar to that used in the case of a life annuity, save that we consider the survivors at the beginning of each year for 20 years only, instead of until age 95. To find the net annual premium of a twenty-payment life, divide the net single premium of a whole-life policy by the value of a 20-year temporary annuity.

Term Insurance. A form of temporary protection is offered by what is known as term insurance. A 20-year term policy, for illustration, is payable only at death, and then only in case death occurs within the 20 years. At the end of that period the policy terminates without further value. The net single premium of a 20-year term policy is computed by a process similar to that used in computing the net single premium of a whole-life policy, save that the deaths of only 20 years are considered. To find the net annual premium, divide the net single premium by the value of a 20-year annuity.

Endowment Policy. A pure endowment policy is one which is payable only to those who live to complete the endowment period. Those that die before the end of that period receive nothing. Of 63,364 persons taking pure endowment insurance at age 56, only 23,761, according to the table, will live to receive the endowment at the end of 20 years. This would call for the payment at that time of $23,761,000. To find the net single premium, divide the present worth of this sum by 63,364, the number of persons insured. To find the net annual premium, divide the net single premium by the value of a 20-year annuity.

Regular endowment insurance provides for the payment of the face amount of the policy to the beneficiaries of any who die during the endowment period and to those policyholders themselves who live until the end of the period. This policy may be regarded as a combination of term insurance and pure endowment. Under the former, those who die during the endowment period are paid, and under the latter those who live to the end of the period are paid. The net annual premium of a 20-year endowment policy consists of the net annual premium of a 20-year term policy plus the net annual premium of a 20-year pure endowment.

Endowment insurance does not differ in essence from whole-life insurance. The companies will issue endowments for various periods, to mature in 20, 30, 40 years, etc. An ordinary life policy issued at age 56 matures by the death of the insured in 40 years at the attained age of 96 or earlier, at which time the full amount will be payable. Likewise, a 40-year endowment policy issued at age 56 would mature at the attained age of 96 or at prior death. In other words, the net premium for an ordinary life policy issued at age 56 would be precisely the same in amount as the net premium for a 40-year endowment, and the two policies will be in every particular essentially the same.

Step-Rate Insurance. Natural premium insurance, yearly renewable term insurance, the step-rate plan, etc., are terms representing a form of policy which provides protection at current cost from year to year, the premium increasing yearly as the insured advances in age. To illustrate: of 63,364 persons at age 56, 1260, according to the mortality table, will die in the ensuing 12 months. Theoretically, death claims are payable at the end of the policy year, so that in this case the sum of $1,260,000 will be required at the end of the first year. The present worth of this fund discounted at 3 per cent would be $1,223,300.98. Dividing this sum by 63,364, the number of contributors, we get $19.31, the net premium which each contributor must pay at the beginning of the first year. Entering upon the second year at age 57, there will still be 62,104 of the original number living, of whom 1325 will be dead at the end of that year. Computing the premium in the same manner as in the first year, we find that the net premium to be paid at the beginning of the second year is $20.71. In like manner the net premium at the beginning of the third year is $22.27. At age 70, the natural premium would be $60.19; at 80, $140.26; at 90, $441.31; and at 95, $970.87. It will be seen that while this form of protection is comparatively cheap in the earlier years, the cost becomes prohibitive in advanced age.

Loading. In the matter of loading there is considerable diversity. The loading is the sum added to the net premium to provide for expense of management and for contingencies, the greater part usually being required for expenses. The loading varies greatly in different companies and in different forms of insurance. In participating insurance, issued by purely mutual companies or by stock companies operating on the mutual plan, so much of the premiums paid as can be saved by reason of safe and profitable investments and an economical management is refunded to the policyholders in the form of so-called dividends. In nonparticipating insurance all that may be thus saved from the premiums paid commonly reverts to stockholders. In participating policies the loading is generally about 25 per cent of the gross premium; while in nonparticipating insurance it is much less, sometimes little more than nominal, the management relying largely upon the gain from excess interest earned and the gain from saving in mortality for payment of expenses and dividends to stockholders.

During several decades prior to 1906, owing chiefly to keen competition for new business, the expense of management had increased to an unwarranted extent. By the New York law, enacted in 1906, certain restrictions calculated to reduce the expense of management to the minimum were imposed upon the companies. One immediate effect of these restrictions was the withdrawal from New York State of a number of companies not domiciled therein; but the expenses of all domestic companies and of all foreign companies continuing to do business in New York are now much lower than formerly, and lower in almost all cases than those of companies not conforming to the New York law. Indeed, all companies doing business in New York are competing keenly with one another in their efforts to reduce the expense of management to the lowest point consistent with business efficiency, and to furnish life insurance at the lowest possible net cost. Again, while expenses in every other line of business have largely increased in the last two or three decades, the net cost of life insurance to-day, in most companies of the better class, is lower than at any previous time in many years. The publicity which insurance departments now require of the companies in respect of every phase of their business renders it impossible for the latter to conceal the cost of new business, or other expenses, even were they disposed to do so. Whether the loading is relatively large or small has little bearing on the cost of life insurance. All companies operating on the mutual plan return to the insured (in most cases annually) the unused portion of the loading in the form of so-called dividends. An important office of the loading is to provide for unforeseen contingencies, such as a mortality in excess of the tabular, a rate of interest earned less than that assumed, an increase in cost resulting from adverse legislation, wars, pestilence, exorbitant taxation, etc. The larger the loading the better equipped will the company be to withstand any unusual strain that may come; while in the absence of any adverse contingencies the excess loading is promptly returned to the insured.

Medical Examination. The early mortality tables were constructed on the basis of the mortality of the general population. In the absence of restrictions it is obvious that insurance companies would suffer from an unfavorable selection of risks. The unhealthy and the weak would seek the benefits of insurance, while the strong and healthy would make comparatively little use of it. To avoid such unfavorable selection, insurance companies endeavor to limit their operations to persons of average expectation of life and to bar out those below the average. In the beginning, therefore, insured lives are a selected class, and might be expected to show a death rate considerably below the average for the general population. It is commonly claimed, however, that through the tendency of the stronger to surrender their insurance readily and of the weaker to keep theirs up as long as possible, the entire benefit of the original selection is lost within five or six years.

The original selection of risks was made chiefly on the results of the medical examination. The medical examiner is required to ascertain from the applicant personally all needed facts relating to family and personal history, as well as to present physical condition and evidences of past disease. Among the facts to be elicited are the following: age and occupation, residence; whether or not he has been rejected or postponed because of illness or risk; use of liquors and of tobacco; service in army or navy, or rejection by recruiting officer; height and weight; race and sex; presence of hernia, or results of accident or injury; hereditary influences, as inferred from age and condition of health of parents and of four grandparents, if still alive or at time of death, with cause of death in each case; similar facts regarding brothers and sisters; existence of pulmonary tuberculosis or insanity in any part of family; all diseases from which applicant has suffered, with date, duration, severity, and result in each case, as well as name of attending physician; present condition of physical health and evidence of tendencies towards disease. Moral hazard must be considered as well as physical condition. From this information the examiner is asked to judge of the risk as a partial guide for the medical director.

Termination of Policies. There are five ways in which life-insurance policies may be terminated: by maturity, by death, by expiry, by lapse, or by surrender. The method of settling endowment policies at maturity is simple and presents few points of interest. The payment of death claims is hedged about with more formality. Formerly companies were disposed to take advantage of technicalities in order to avoid paying claims of doubtful validity, but now reputable companies show commendable willingness to settle on receipt of proofs of death when fraud is not apparent. In the nature of things the chief reliance for such proof is on medical testimony. The termination of a pure endowment by death and the discontinuance of a term policy at the end of the period for which it was issued are examples of termination by expiry.

Lapses and Surrenders. A policy is said to lapse when it terminates through failure to pay an accruing premium, the default occurring before a surrender value of any kind has accrued. A policy is surrendered when it is terminated at the request of the policyholder, or by failure to pay an accruing premium, after a surrender value in the form of cash, paid-up, or extended insurance has accrued or is allowed. The proportion of policies surrendered or permitted to lapse is large. A great many deferred-dividend policies are surrendered at the completion of the dividend period, the policyholder treating them as endowment insurance, the guaranteed cash value and the accruing dividend together frequently approximating, and sometimes exceeding, the face amount of the policy. Surrenders are also largely increased through policy loans. The loan values contained in modern policies are a constant temptation to borrow to meet some real or fancied need. Such loans are rarely repaid directly, but are deducted from the proceeds of the policy at death, or from the guaranteed cash value in case of default in payment of premium or interest. Most policies carrying loans are surrendered sooner or later. During the five years 1909–1913 the regular life-insurance companies reporting continuously to the New York Insurance Department issued policies on which the first premiums were actually paid which carried insurance to the amount of $7,870,665,643; during the same five years they wrote off their books $4,590,727,729. The amount terminated by lapse or surrender was $2,978,302,102. In 1913 the amount terminated in regular ways was $355,725,818, while $723,469,303 was terminated by lapse or surrender.

Reserve and Surplus. The general public has ordinarily very confused ideas regarding the reserve in life insurance. Simply defined, the so-called reserve is merely the insurance fund—the fund from which all policy claims are paid. No policy is ever paid, either in whole or in part, from any other source; nor can any part of the reserve be applied legitimately to any other use than the payment of policy claims. In illustration we again take the example of 63,364 persons at age 56 insured for $1000 each on the ordinary life plan. The net premium (exclusive of loading) to be paid annually by each policyholder until death is $47.76 (carried to six decimal places, the net premium is $47.760895). That part of the premium which constitutes the loading, being for expenses and contingencies only, is not considered in this illustration. The initial reserve, or insurance fund, at the beginning of the first policy year consists of the total net premiums paid by the 63,364 policyholders, amounting to $3,026,321.35. To this fund we add 3 per cent ($90,789.64) on account of interest, the premium having been calculated on the assumption that the interest earned each year would be sufficient to increase the reserve at that rate. Adding the interest we get $3,117,110.99, which is the maximum reserve, or insurance fund, of the first year. According to the table 1260 of our 63,364 policyholders will die in the first year, calling for the payment of $1,260,000 in death claims. Deducting this sum from the total reserve we have a balance of $1,857,110.99, which is the terminal reserve of the first year. Twelve hundred and sixty policyholders having died during the year, there are 62,104 still living. The terminal reserve of $1,857,110.99 is the property of these living policyholders as a body, not as individuals. If the fund were to be divided, however, the pro rata share of each policyholder would be $29.90. This is the individual policy reserve at the end of the first year, but it is not the property of the individual policyholder, nor can any part of it be withdrawn by him save as may be provided in his policy.

At the beginning of the second year the net premiums paid by the 62,104 living policyholders amount to $2,966,142.62. To this sum we add the terminal reserve of the first year, $1,857,110.99, making the initial reserve at the beginning of the second year $4,823,253.61. To this amount add 3 per cent as before, and from the sum deduct $1,325,000 in payment of the death claims of the 1325 policyholders who, according to the mortality table, die in that year. This will leave a balance of $3,642,951.22, which is the terminal reserve, or insurance fund, of the second year, the pro rata share pertaining to each policy being now $59.94.

To complete the illustration proceed in the same manner, collecting the net premium of $47.76 from each policyholder living at the beginning of each subsequent year as indicated by the mortality table; add to the net premium income the terminal reserve of the previous year; to the initial reserve thus obtained add 3 per cent; and from the sum total deduct the death claims of the year as indicated by the table. At the end of the third year the total terminal reserve will be found to be $5,348,184.98, and at the end of the fourteenth year $15,837,373.42. The policyholders still living at the beginning of the fifteenth year are now all 70 years of age, and the tabular death claims of the year will aggregate $2,391,000, a sum in excess of the total net premium income and interest combined. From this time on the drain upon the reserve, or insurance fund, will increase rapidly, and the balance on hand each year will decrease accordingly, for from the beginning no new members have been received to add to the premium income. At the beginning of the twenty-fifth year only 14,474 policyholders are still living and these are 80 years of age; the net premium income is only $691,291.19, and the reserve at the end of the year only $8,376,129.16. As 2091 deaths have occurred during the year, the individual policy reserve at the end of the year is $676.42. At the end of the thirty-fourth year, when the 847 policyholders still living have attained the age of 90 years, the terminal reserve of $724,542.93 is equivalent to an individual policy reserve of $855.42. At the end of the thirty-ninth year, three policyholders, according to the table, will still be living at the attained age of 95. The total reserve or insurance fund will be only $2,769.34, but this is equivalent to an individual policy reserve of $923.11. We now enter upon the fortieth year and the three living members will contribute the sum of $143.28 in premiums. Adding to this premium income the terminal reserve of the previous year, $2,769.34, we have an initial reserve of $2,912.62. Adding

3 per cent, $87.38, we have a total insurance fund or reserve of $3000, or just sufficient to pay the three remaining policies in full; for, according to the mortality table, the three remaining members will not live beyond the end of that year, or beyond the attained age of 96.

Observe that the pro rata reserve pertaining to each policy increases yearly as the insured advances in age, the reserve of a life policy becoming equal to the face amount of the insurance at the attained age of 96. The illustration takes no account of additional lives insured, for the premiums to be paid by the 63,364 policyholders must be sufficient with interest to provide for all death claims occurring in their own number, without depending upon the addition of new blood. No account of lapses or withdrawals is taken in the illustration, for the company is bound to carry every policy to maturity if premiums are duly paid, and it can do no less than assume that every policy will persist to the end. It must therefore be prepared to pay every policy in full when it matures. Lapses and surrenders there will be, but they will not affect the reserve values of the remaining policies. A policy which has been in force the required length of time can be surrendered, and a part or all of the reserve pertaining to that policy may then be withdrawn, as stipulated in the contract. In most companies no surrender value is allowed until the end of the second year, and many allow nothing until the policy has been in force three years. In all companies the surrender value in the earlier years is less than the full reserve pertaining to the policy, but it increases gradually thereafter. Two or three companies allow the full reserve as a surrender value at the end of the third year, many companies do not allow the full reserve until the end of the tenth year, and a large number not until the end of the fifteenth year. When a policy lapses, or when it is surrendered for value, so much of the reserve as may not have been conceded to the withdrawing policyholder is carried to surplus and the reserves of the remaining policies are neither increased nor decreased by the withdrawal. Although the forfeited reserves of lapsed or surrendered policies become surplus, it is not considered that there is any real gain from this source. On the contrary, the withdrawal of sound lives, secured originally at considerable expense, is universally regarded as detrimental to the interests of the company, i.e., to the interests of the remaining policyholders.

In the States whose laws provide for efficient supervision of insurance, the mortality table to be used and the interest rate to be assumed in calculating net premiums are prescribed by law. In most States the American Experience Table of Mortality and a maximum interest rate of 3½ per cent are prescribed, although 4 per cent is permitted in some States. Most of the more prominent mutual companies assume only 3 per cent. This means larger net premiums and reserves than when the assumed rate is 3½ or 4 per cent, and is in the interest of strength and safety.

Dividends. If in practice the mortality experience of a life-insurance company corresponded precisely with that indicated by the mortality table employed, if the rate of interest earned proved always to be the same as that assumed in the calculation of the premium, and if the loading added to the net premium were always just sufficient to provide for the expense of management and for contingencies, the premiums collected on outstanding policies would always be precisely sufficient to pay all death claims, maturing endowments, and other policy claims until the last policy outstanding had matured. There would be no surplus from any source. In actual experience, however, the mortality incurred by a well-managed company proves to be less than the tabular, the interest earned is greater than the assumed rate, and the loading is more than sufficient to provide for expenses and contingencies. From each of the three sources named, therefore, there is a gain—a gain from saving in mortality, a gain from excess interest earned, and a gain from saving in loading. This gain, however, is not a profit on an investment but merely a saving in the estimated cost of life insurance. The premium charged has proved larger than was required for the payment of claims, and in mutual companies the excess will be refunded to the policyholder in the form of a so-called dividend. The New York law requires that the surplus thus accruing shall be distributed among the policyholders "annually and not otherwise," save that a limited portion must be set aside and retained permanently as a contingency reserve, to provide for possible future losses of invested funds, excessive mortality, or other unforeseen contingencies. In stock companies not operating on the mutual plan the accruing surplus belongs to the stockholders, though the stock company, in lieu of apportioning dividends to the policyholders, charges smaller premiums than the mutual company. Some stock companies, though controlled by the stockholders, conduct their business in other respects on the mutual plan, apportioning the accruing surplus to policyholders in the same manner as purely mutual companies. These are called mixed companies.

The surplus in practically all American companies is distributed upon what is known as the contribution plan, under which the holder of a participating policy receives so much of the accruing surplus as has resulted from the premiums paid by him. The apportionment of dividends, however, is not an exact science and the formulæ used by different companies for making the distribution vary slightly according to the judgment of the actuaries, though without doubt approximate justice is always done. In the case of policies written since the 31st of December, 1906, practically all distributions are made on the annual dividend plan. Prior to the date named a number of companies distributed the surplus annually, or deferred the distribution to the end of a stated period, as requested by the insured in his application. The deferred dividend period was usually 5, 10, 15, or 20 years, and the surplus accruing during that period was distributed among the policies in force at the end of the period. Under this plan policies terminating by death, surrender, or lapse during the period received no dividends, the surplus lost by them inuring to the benefit of those that persisted to the end of the period.

Control of Life-Insurance Companies. The control of a mutual life-insurance company rests, in the last analysis, with the policyholders; that of a joint-stock company with the stockholders. But it is generally recognized that the life-insurance business is essentially mutual. The policyholders of the stock company own the reserve or insurance fund, but not the surplus; and although the management of the business is in the control of the stockholders, the rights of policyholders are fully protected by the insurance laws. Immediate control of an insurance company rests in a board of directors, elected by the stockholders in a joint-stock company and by the policyholders in a mutual company.

In order to bring the management of mutual life-insurance companies under the control of the policyholders, the New York Legislature enacted in 1906 a law requiring the removal of the existing directorates of the mutual companies of that State and the election of new boards, invalidating all existing proxies and limiting the validity of new proxies to two months, and prescribing in detail methods of voting in person, by mail, and by proxy. The law also required that the lists of policyholders should be accessible to any policyholder. The law further contained provisions for facilitating the transformation of existing joint-stock companies into mutual companies.

While frequent changes in management are undesirable, and annual struggles for the control of a company, like that carried on in 1906 between the existing management and the International Policyholders' Committee for the control of the New York Life and the Mutual, tend to impair public confidence in the companies, it is generally believed that as a rule the management will have sufficient influence to continue itself in power so long as its policy is generally approved.

Investments of Life-Insurance Companies. The reserves and surplus of the life-insurance companies represent capital for investment amounting (in 1913) to $4,417,298,211 for the companies reporting to the New York Insurance Department. These funds are specially adapted for permanent investment, since under ordinary conditions, with the business of the company remaining stationary, the income from premiums and investments is at least equal to all the expenditures. The fundamental requirements of all investments of life-insurance companies are (1) security of the principal; (2) certainty of income; and (3) the highest income compatible with these requirements. Other things being equal, the higher the interest return, the lower will premiums need to be, or the higher the dividends.

Mortgages on improved real estate, restricted to a limited proportion of the value of the property, meet the above requirements admirably. If due care is exercised by the company in making such loans, they are among the most secure and profitable of investments. The expense of administering such assets is, however, considerable, and the business would become unwieldy with large companies. Real estate itself, as it continually fluctuates in value, is a doubtful form of investment.

The bonds of municipalities in States where municipal corporations are carefully restricted as to their debt-incurring powers form an investment which is secure, easily administered, and profitable. State bonds may be very satisfactory, but the possibility of repudiation exists.

Loans to policyholders upon their own policies, the amount of the loan being restricted to the reserve on the policy, are a perfectly safe investment for the insurance company, and yield a return above the average. Such loans form a considerable part of the investments of most companies. Recent experience, however, indicates that the right of a policyholder to demand a loan at any time on the pledge of his policy, as required by recent laws, may prove detrimental to the interests of the policyholders as a body. In a time of long-continued financial depression the demand for loans or cash value might easily exceed the surplus income of the company. To meet such demands the company might be compelled to sell valuable securities on a depressed market at heavy loss, and in any event it would be precluded from buying high-class bonds at the favorable rates then prevailing. For these and other reasons the National Convention of Insurance Commissioners has recommended a modification of existing laws to authorize the companies to defer the granting of loans or the payment of cash values for a period of six months after demand.

The bonds of great private corporations, excluding industrials, are an exceedingly common form of investment and, with reasonable care on the part of the investing companies, meet all the requirements as to security of principal and certainty of interest. Their yield is often low, as they are much in demand by other investing agencies. Corporation stocks, on the other hand, are generally regarded as unsuitable for the investment of life-insurance funds. They may be quite secure as to income; but their value is constantly fluctuating. In a time of panic the value of such assets might easily shrink to such an extent that an insurance company which had invested largely in them would fall below the minimum of assets required by law for the protection of its reserves, and so be forced into liquidation.

The holder of corporate stocks, moreover, becomes in the measure of his holdings responsible for the management of the companies whose stock he holds. Thus, the insurance companies, through stock holdings in banks, trust companies, railroads, and the like, were forced to concern themselves with the management of business wholly foreign to life insurance, and often to the detriment of the life-insurance business. The New York law now prohibits life insurance companies from investing in corporation stocks, and requires them to dispose of present holdings at an early date.

The assets of the life-insurance companies reporting to the New York department consisted on Jan. 1, 1913, of real estate, $147,078,103; bonds and mortgages, $1,453,931,586; stocks and bonds, $2,014,080,445; collateral loans, $14,317,215; loans on policies to policyholders, $589,312,568; premium notes and loans, $25,612,561; cash in office or bank, $55,403,435; deferred and unpaid premiums, $55,588,366; other assets, $61,973,932; a total of $4,417,298,211. The item classed as stocks and bonds, making nearly one-half of the total assets, consists mainly of securities which find a ready market and are therefore subject to constant fluctuations in their market value, though the real value of bonds is not affected by the daily market quotations. High-class bonds (and life-insurance companies buy no other) are purchased by the companies as a permanent investment for the sake of the income they yield. This income is a fixed percentage of the par value, does not fluctuate in amount, and will be received by the company yearly until the maturity of the bond, the face amount of which will then be paid. These particulars are as certain in the case of high-class bonds as of the best real-estate mortgages.

Obviously such heavy investment in securities many of which are subject to speculative dealings gives the insurance companies a position of extraordinary influence in the financial world. In the floating of a new issue of corporation bonds, or the launching of a new corporation, the support of insurance investment was formerly a factor hard to overestimate. Hence arose the practice of participation by the life-insurance companies in syndicates formed to underwrite large issues of corporate securities. The companies participating in such transactions, as ordinary speculators, disposed of the securities contracted for at an advanced price; and in most cases the syndicate transactions of the past years proved profitable to the companies. At the same time the business was hazardous; and the participation of life-insurance companies in underwriting syndicates has been generally condemned as unsound policy, and is now prohibited by the New York law.

Legislation. The chief activity of State governments in the United States in respect of life insurance is supervision and restraint. The history of life insurance in the United States has shown a marked tendency on the part of some companies to recklessness in the matter of reserves, and it is only the activity of the government which has induced the companies to give to their policyholders adequate protection. Massachusetts was the first State to establish an insurance department (1855). It was also the first State to adopt a scientific method of insuring the solvency of an insurance company. That method is, in brief, to compel it to carry a reserve sufficient to reinsure all its outstanding risks at net premium rates; that is, a reserve which is called for by a calculation based on a specified mortality table and rate of discount. The Actuaries' Table and 4 per cent were specified in the Massachusetts law, and were adopted by most of the other States as they introduced the net valuation test of solvency. Some States, however, authorize the use of a discount rate of 4½ per cent, which diminishes somewhat the amount of reserve required. New York originally used the American Experience Table, then changed to the Actuaries' Table with 4 per cent interest, and Jan. 1, 1901, in recognition of the fall of the rate of interest in safe investments, returned to the American Table of Mortality with interest of 3½ per cent. This has materially increased the amount of reserve necessary for the companies to carry. All the leading mutual companies of New York now (1914) voluntarily use a 3 per cent rate in valuation of new business.

Laws taxing the premiums collected by life-insurance companies within a State are virtually universal. The total taxes paid by the companies in the United States is estimated at $13,000,000 yearly. Such laws are regarded by insurance men as wholly unjustifiable, since they tend to discourage men from making due provision for their families in case of death. Much of the other State legislation, also, is of an unnecessarily burdensome nature. It has been estimated that the total cost of inspection, as conducted by the various States, is at least eight times as great as inspection by a single authority would be. This burden is in most cases borne by the companies.

Formerly a considerable number of the insurance bills proposed in the various State legislatures were chiefly designed, it is alleged, to blackmail the companies. Complaints on this score now are very rare. Apart from blackmailing legislation, there are many laws proposed which the insurance companies are bound to oppose, in the interests of their policyholders. The New York legislative investigation in 1905 disclosed the fact that some of the companies retained agents to watch legislation and to employ appropriate means to defeat obnoxious measures. This work is now in the hands of the Association of Life Insurance Presidents, representing the leading companies of the country. The New York Law of 1906 requires every agent representing a corporation before the New York Legislature to file with the Secretary of State a statement of the services he expects to perform, and to make public a sworn statement of all expenditures incurred.

This law limited the expenses for new business, the total expenses, the new business a company might do annually, and the contingency reserve, or surplus, which it might hold. Companies incorporated in other States and doing business in New York were required to conform to the expense limitations, and the limitation upon new business was afterward imposed on them. The first three limitations named above have since been considerably modified.

Exclusive Federal regulation of insurance is now conceded to be impracticable save by an amendment to the Constitution of the United States, since the Supreme Court has held (Paul *v.* Virginia) that insurance contracts are not articles of commerce and cannot be brought under the Interstate Commerce clause of the Constitution. Discussion of such regulation was an outgrowth of the New York investigation. Under the pressure of popular demand, a legislative commission was appointed in the special session of the New York Legislature of 1905 to examine into the business of the principal life-insurance companies doing business in the State. The commission, consisting of three senators and five assemblymen, with Senator W. W. Armstrong as chairman, began its sessions Sept. 6, 1905, having secured Charles E. Hughes as counsel. The principal companies investigated were the Equitable Life Assurance Society, the New York Life, the Metropolitan Life, and the Mutual Life of New York. As a result of the exposures made by the legislative committee, radical reforms were made in several companies. On Feb. 22, 1906, the Armstrong Committee submitted its report on the insurance companies to the Legislature, and recommended a thoroughgoing reform of insurance legislation. Its recommendations were practically embodied in the Law of 1906, the important provisions of which have already been discussed. See INSURANCE.

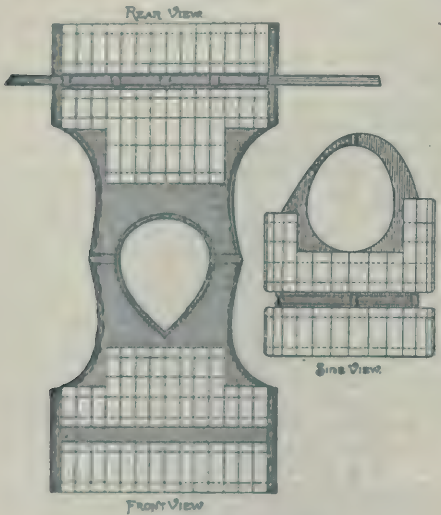
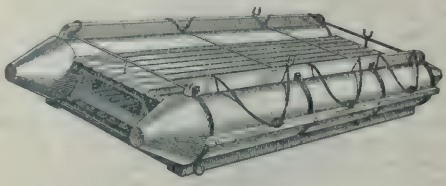
LIFE MORTARS AND ROCKETS. See Life-Saving Guns and Rockets; Life-Saving Service.

LIFE PRESERVERS. Contrivances adjustable to the body for buoying up persons in the water. They are made of various materials and in various forms. The best kind of ordinary life preserver, such as is used on passenger vessels, is made of good, sound cork blocks, or other suitable substance, with belts and shoulder straps properly attached, and so constructed as to place the cork underneath the shoulders and around the body of the person wearing it. It should contain at least six pounds of good cork and have a buoyancy of 24 pounds. Cork cushions, with belts and shoulder straps, are considered good substitutes for the jacket above described when they have the proper buoyancy. Life preservers of an approved pattern are required by law on passenger vessels in the United States, and it is the duty of the inspecting officers to see that they are adequate and serviceable. Oarsmen in the life-saving service of the Coast Guard use an improved belt made of blocks of cork fastened to a cloth lining as shown in the cut. The man adjusts it by thrusting his head through the hole in the lining, the front and back parts falling into position and being secured by a lashing around the waist. This method obviates the necessity for shoulder straps, and, there being but one knot to tie or unfasten, the belt can be readily put on and removed. Tule, deer hair, and kapok are used to some extent in the construction of life preservers. Those in the form of inflated vests and overcoats are seen in service occasionally, and in the British navy swimming collars of rubber inflated were issued during the Great European War of 1914. Waterproof, air-tight life-preserving suits, consisting of headdress, jacket, and trousers, made of rubber or similar material, are seldom employed at the present time except by divers. See Safety at Sea.



A LIFE-SAVING CORK JACKET.

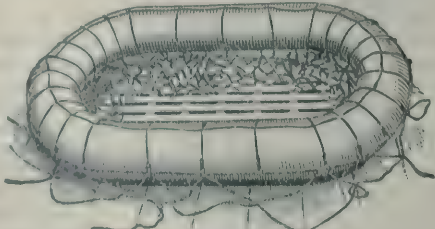
LIFE RAFTS. Structures used in saving life at sea. Nowadays nearly all seagoing steamers carry a certain number of rafts, of some approved description, as an equivalent for a portion of the small-boat capacity they are required to maintain. These floats, as a rule, can be conveniently stowed, are easily transported from one part of the vessel to another, may be launched overboard anywhere, and sometimes prove better instruments than boats for saving the shipwrecked. The devices of this kind are well-nigh innumerable. All depend for their extra buoyancy upon some ingenious method of utilizing air receptacles, cork, etc. Rafts and floats intended to be carried on the decks of ocean steamers must have 4½ cubic feet of inclosed air space for each person that they will accommodate, and those for steamers on lakes, bays, sounds, and rivers, 3½ cubic feet of air space for each person. Such rafts are equipped with life lines and oars.



ORDINARY CYLINDER LIFE RAFT.

An effective contrivance, which is much used on passenger and other vessels, is the metallic cylinder life raft, consisting of two cylinders, cone-shaped at the ends, firmly connected with cross rods, and having slats running longitudinally between the hollow forms. This raft owes its great buoyancy to the air-filled cylinders.

The Carley life float is another and later form of raft. It consists of a copper tube, shaped like an ellipse, which is divided into air-tight compartments. The tube is sheathed with cork, the whole being covered with canvas and made water-tight. A bottom, composed of wooden slats, is suspended from the interior sides of the float by a rope netting about 3 feet deep. The netting is so arranged that, whichever side of the float may fall upon the water, the slatted

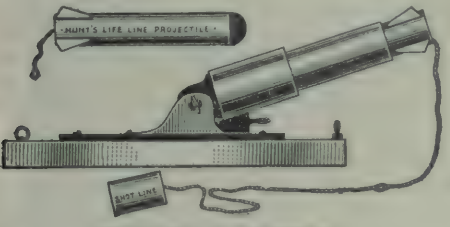


CARLEY LIFE FLOAT.

bottom will go undermost. Oars and a signal flag are lashed to the tube. A large number of persons can be supported by this device, which is constructed in various sizes. See Safety at Sea.

LIFE RENT. In Scots law, the usufruct, i.e., the right to the beneficial use and enjoyment of a heritable estate for life, the person entitled thereto being called a life renter. The estate is nearly equivalent to the life estate of the English and American law, its distinctive features being derived from the Roman or civil-law system, on which the law of Scotland is based. See Civil Law; Life Estate; Usufruct.

LIFE-SAVING GUNS AND ROCKETS. Ordnance used to fire line-carrying projectiles from the shore to a wrecked vessel or vice versa. The Lyle gun, which is more generally used in the United States than any other, is described under Life-Saving Service. American ocean-going steamers are required to be supplied with some approved means of firing lines to the shore. The Hunt gun and Cunningham rocket are employed by many for such a purpose. The former, which was devised by Edmund S. Hunt, of Massachusetts, is mounted on a flat wooden carriage, to which it is fastened at the cascabel by a hinge. Elevation is obtained by use of a quoin between the forward part of the carriage and the under side of the gun. The projectile is the chief feature of the apparatus and consists of a cylindrical tube of tin, into one end of which is soldered a solid hemispherical shot which rests on the cartridge in the gun. About half the shot line is coiled in the tube, from which it pays out during flight, the balance of the line being in a can or on a reel placed on the ground or deck. When the gun is discharged, the weight of the line causes the projectile to reverse similar to the Lyle method. The Massachusetts Humane Society uses the Hunt gun, which has a range of more than 700 yards. The rocket, which is the invention of Patrick Cunningham, of the same State, consists essentially in a head carrying the projectile charge, in combination with a tube adapted and arranged to contain a coiled line. The latter is connected with a shore or deck line in the same manner as the Hunt system. This is a powerful rocket having a range of 1000 yards with a small line. It is fired from a stand. Guns, rockets, or mortars, of various designs, are used by all life-saving institutions for effecting line communication with stranded vessels. For other life-saving appliances, see Life-Saving Service.



HUNT GUN AND PROJECTILE.

LIFE-SAVING SERVICE. By Act of Congress approved Jan. 28, 1915, the Life-Saving Service and Revenue Cutter Service were united under the name of the Coast Guard. The union is designed to secure certain advantages of an administrative character affecting both services and to give the field force of the Life-Saving Service the benefits of retirement pensions after a long period of faithful and honorable service, or upon becoming incapacitated through injury or disease incurred in the service. The Coast Guard becomes a part of the military force of the nation and in time of war forms a naval reserve of 4000 men. The organization of the field force of the Life-Saving Service, with its stations, boats, apparatus, and other equipment, as well as its former functions and methods of operation hereinafter described, remain unchanged. The Life-Saving Service of the United States was organized under the present system in 1871. Previously, however, a number of small boathouses had been located on the coasts of Long Island and New Jersey, placed in charge of officers known as keepers, and imperfectly equipped with boats and appliances for the use of such of the coast residents as might volunteer to serve without compensation upon occasions of disaster. The Act of April 20, 1871, gave the Secretary of the Treasury authority to establish additional stations on the coasts of Long Island and New Jersey, and to employ crews of experienced surfmen at such stations and for such periods as he might deem necessary, at a compensation not to exceed $40 per month. Upon this limited authority the inauguration of the existing system was undertaken. Subsequent legislation has extended it to embrace the entire ocean and lake coasts of the United States and has added many improvements. Its purpose primarily is to save life from wrecked or imperiled vessels near the shore by means of organized equipment and effort. Next to the rescue of life is the saving of marine property.

In 1807 the Massachusetts Humane Society, a benevolent organization, placed a lifeboat station at Cohasset, which was the first regular attempt in this country to render direct aid to the shipwrecked from the shore. Later the society built a number of small stations and enlarged materially the scope of its work. The creation and extension of the government service, however, relieved the society of much of its charge, although it still maintains some 43 small houses, equipped with boats and line-carrying guns, on the Massachusetts coast. Between 1848 and 1871 Congress made occasional small appropriations, commencing with one of $10,000 in the former year, for providing means for the rescue of life and property from shipwreck, and under the authority of such fragmentary legislation a number of houses were established along the seaboard furnished with boats and some other life-saving appliances. Lifeboats were also placed at scattered points on the Atlantic and lake coasts. The stations erected had to rely upon volunteers from among the fishermen in the various localities to man the boats and apparatus as occasion required. While there was much of value in this inchoate service, its defects were many and serious. Finally the occurrence of a number of disasters to vessels and their crews on the Atlantic coast, disclosing the inadequacy of the means of succor then at hand, so aroused public sentiment as to cause the enactment of national legislation, upon which the present life-saving system is based. It is the only governmental service, all other life-saving institutions, except one or two small European organizations, being maintained wholly or in part by private contribution.

At the close of the fiscal year which ended June 30, 1914, there were 285 stations included in the service. Of these 203 were situated on the coasts of the Atlantic Ocean and the Gulf of Mexico, 62 on the shores of the Great Lakes, 19 on the Pacific coast, and 1 at the falls of the Ohio River, Louisville, Ky. Eight stations included in this summary were houses of refuge on the eastern coast of Florida. For the convenience of administration, the sea and lake coasts, which have a general extent of about 10,000 miles, exclusive of Alaska, are divided into separate districts numbered from 1 to 13 inclusive. These districts have been fixed with reference to the conformation of the shores, there being 8 on the Atlantic, 1 on the Gulf, 1 on the Pacific, and 3 on the Lakes, one of the last named (the tenth) including the station at the falls of the Ohio River.

The station buildings are located at points of danger to shipping, most of them being at exposed places. Those on the ocean coast are generally two-story wooden structures, built to withstand severe winds and the encroachment of storm tides, and, when conditions permit, are placed sufficiently back of high-water mark to make them safe. The stations on the lakes are similar to those on the seashore. Many of them, however, are located in the vicinity of harbors, behind piers or breakwaters, and are specially devised for the use of the heavy lifeboats employed in that region. The interiors of the buildings are divided into suitable apartments for the accommodation of the crews and the reception of the life-saving appliances, the largest space being allotted to the boatroom, from which a sloping platform leads for the running out of the heavier equipments. Stations exposed to view from offshore are so painted that they can be distinguished a long distance. Each has a lookout tower or platform, where the day watch is kept, and is marked by a flagstaff that may be used in signaling passing vessels. Two stations, the one on the Ohio River and another in Boston harbor, are house boats or floating stations, which are moored in their respective localities and are equipped and manned for their special purposes. The houses of refuge on the coast of Florida are small dwellings, each large enough for the residence of one man, who has charge, and his family. They are supplied with provisions and other necessaries and are intended for places of shelter only, as the character of the neighboring shores makes it possible for wrecked persons to reach the land with little difficulty, their chief danger being from hunger and thirst.

The stations are designated by local names indicating their positions. When they are near each other, some being not more than 4 or 5 miles apart, they are connected with telephone lines, which makes it easy to concentrate two or more crews in combined effort at the scene of wrecks. It often happens that several vessels strand at the same time in the same neighborhood, and for this reason it is desirable to have means to assemble speedily the necessary force to assist them. Whenever practicable, unadjacent stations are connected with the nearest available point that will put them within telegraphic reach. The telephone lines of the service are of value to the commercial interests of the country, as they are used in giving maritime exchanges, underwriters, and others concerned early notice of disasters, and in advising them of the condition of wrecked vessels and their cargoes. During the war with Spain the telephone system was used by the surfmen as a military coast signal service.

The stations on the Atlantic and Gulf coasts, with the exception of the floating station at Boston, are manned from August 1 to May 31 of each year. In the months of June and July, termed the inactive season, the keepers alone are in charge on those coasts, that being the period least liable to high winds and rough water. The members of the crews, however, who are off duty at that time are required to respond promptly to any call for assistance that may reach them and are paid for services rendered on such an occasion, while volunteers are also relied upon in case it becomes necessary to attend a wreck. Stations on the Pacific coast, and the one at Louisville, are manned continuously, while on the Great Lakes active service covers the interval between the opening and closing of navigation. The floating station in Boston harbor is employed from April 1 to November 30 of each year, its work, like that of the Louisville station, consisting largely in the rescue of imperiled persons from small craft and requiring unremitting vigilance. Its equipment includes a steam launch and two gasoline launches.

A life-saving crew is composed generally of a keeper and from six to eight surfmen, although the number depends a great deal upon the nature of the service they are to perform, in some cases a larger crew being necessary to man a station properly. At most of the stations on the Atlantic coast an extra man is put on during the winter season. A surfman must be a citizen of the United States, not under 18 nor over 40 years of age when originally enlisted, able to read and write the English language, physically sound, a good swimmer, and experienced in the management of boats. Appointments are made upon examination and certification by the Civil Service Commission. Great care is exercised in selecting the men, no one being admitted or promoted to a higher grade who has not furnished manifest proof of his fitness for the position. A vacancy in the keepership of a station is filled by the promotion of a surfman judged to be the most competent available man in the district. There is in each crew a No. 1 surfman—the others being numbered 2, 3, 4, and so on—who ranks next to the keeper and performs that officer's duties in his absence.

The keeper is intrusted with the care of the buildings and their contents and the government of the station. He is the captain of the crew over which he has control. In the boat he takes the steering oar and at other times directs the operations. The crews are put through a rigid course of drills, recitations, and inspections, which the keeper carries out on specified days each week, weather and surf permitting, while the district officers and others in authority make frequent visits to the stations. The drills, which the regulations of the service prescribe, are with the beach apparatus (each station has a drill ground on which is a wreck pole representing the mast of a stranded vessel), surf and life boats, life car, international and general service signal codes, method of resuscitating the apparently drowned, etc. Keepers and surfmen provide themselves with uniforms which they are required to wear at all times when on duty.

The service uses several principal appliances for saving life from shipwreck. The first of these is the cedar surfboat, which is the boat most suitable to launch from flat beaches through

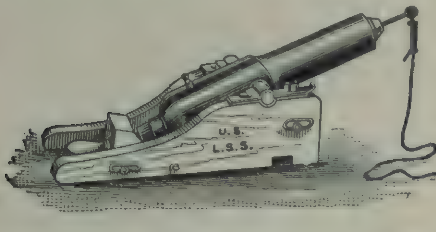
the shoaling waters of the Atlantic and Gulf coasts. The various types of this boat are developments of the boats used in surfing by the fishermen of Long Island and New Jersey when the first stations were placed on those shores. Those in most general use are from 22 to 27 feet long, 6 to 7 feet beam, and are provided with end air chambers which make them insubmergible. Each is completely equipped with oars, boat hooks, boat hatchets, bailing buckets, life preservers, life and righting lines, cork fenders, an anchor, a canvas drogue, heaving stick, etc. This boat, being comparatively light, can easily be hauled alongshore on its carriage. Its action in the hands of the station crew is often marvelous, the boat being manœuvred in the breakers and in proximity to wrecks with great dexterity. It is propelled by from five to eight oars and is expected to carry, besides the crew, from 9 to 12 persons, although as many as 15 have been safely landed at a time in a bad sea.

Other contrivances are the self-bailing and self-righting lifeboat, a reproduction of the English model, and the Beebe-McLellan self-bailing boat of American design. (See LIFEBOAT.) Lifeboats are used with good effect on the Great Lakes, where the conditions favor their employment, are utilized to some extent at selected points on the ocean coast, and often go long distances under sail. The matter of placing boats at stations has always to be carefully considered, as the type which may be suited to one locality may be entirely unfitted for another.

When it is impracticable to use a boat, wreck ordnance is relied upon for communicating with stranded vessels. A small, bronze, smoothbore gun, weighing with its carriage 185 pounds, invented by Col. David A. Lyle of the United States army, is the appliance in general use. It carries an 18-pound elongated cast-iron projectile, in one end of which is an eyebolt or shank that projects sufficiently beyond the muzzle of the gun to protect the line which is fastened to it from being burned off. When the gun is fired, the strain of the line causes the projectile to reverse. A range of nearly 700 yards, with a small shot line, has been obtained with this gun under favorable circumstances, although the piece is not often called upon to cover a range of more than 400 yards.



LYLE GUN.

The breeches buoy is a circular life preserver of cork, about 7½ feet in circumference, to which short canvas breeches are attached. It holds one person, is suspended by lanyards from a hawser, and is drawn to and from the wreck with lines. On account of its being safe as well as light and easy to transport and handle, and from the further consideration that the greater number of vessels now stranding on the coast have small crews, from 6 to 10, it is more frequently used than the life car.

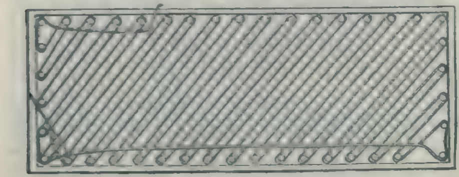
The life car is made of galvanized sheet iron and is shaped like a covered boat with an opening on top, provided with a hatch which may be fastened inside or out. While practically watertight, it has means for supplying air to those within. It is between 10 and 11 feet long, has sufficient capacity for five or six persons, and may be connected with a hawser and hauled in the water to and from a vessel, or can be operated similarly to the breeches buoy. This car has been found very useful in landing sick people and valuables, as they are protected from getting wet.

There are a number of appliances, auxiliary to the principal means of saving life, belonging to the regular outfit of a station. Among these are boat wagons, roller boat skids, apparatus carts, cork jackets, heaving sticks, signal flags, night warning signals, beach torches, patrol lanterns, medicine chests, hawsers, hauling lines, etc. At some points, where the outlying bars are a considerable distance from the shore, powerful line-carrying rockets, which have a greater range than the gun, are kept, but there have been few calls for their use.

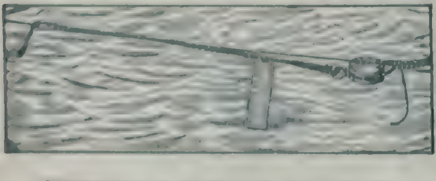
In the day a strict lookout seaward is kept from the stations for distressed craft, and during the night between sunset and dawn, and at all times when the weather is thick and stormy, the patrolmen maintain a steady vigil along the beach. At the beginning of their watch two surfmen from each station follow the shore line in opposite directions until they meet the patrolmen from the adjacent stations, with whom metallic checks, suitably marked, are exchanged and taken to the keepers as proof of the honest performance of duty. When the stations are remote from each other, this scheme, of course, is not practicable, and then the patrolman carries a watchman's clock which can be registered as to time of arrival only by means of a key contained in a post at the limit of his beat. Each man carries, besides a lantern, a night signal which, when exploded by percussion, emits a red flame that flashes far out over the dark waters and warns the unwary ship, approaching too near the breakers and outlying reefs or shoals, of impending danger, or assures the shipwrecked that help is close at hand. The patrol system is a feature that distinguishes the United States service from all others in the world and accounts largely for its unrivaled success in affording relief to seafarers. During the year 1914 198 craft were warned away from dangerous places by the signals of the patrolmen. At some stations, where service is likely to be facilitated by the use of horses, and where the shore is suitable, patrolmen on extended beats are permitted to go mounted.

When the watch, either at night or in the day, discovers a vessel ashore, he takes instant measures to alarm the crew of the station. Sometimes this may be quickly accomplished by use of the telephone in a near-by watch-house; otherwise the surfman must hasten on his errand as best he can. The condition of the weather and surf will indicate to the keeper whether a rescue should be attempted by means of a boat, the breeches buoy, or life car. Either the boat must be hauled on its carriage or the apparatus cart dragged to the scene of the wreck. Draft animals are kept at many stations to facilitate and hasten the transportation of the appliances, but when they are not provided the keeper may hire horses when needed.

If the rescue is to be effected by means of the beach apparatus, no time is lost, after selecting a suitable place abreast of the vessel, in setting up the gear. Each one of the crew proceeds at once to break out the part assigned to his charge and place it in position. The keeper fires the gun, and the slender shot line goes flying over the stranded vessel. This line, to insure its running out without entanglement or friction, has been previously faked over pins, layer upon layer, and inclosed in a box. When brought into use, the box is inverted and the pins are withdrawn, leaving the line disposed in loops so that it will pay out freely. The shot lines are soft-laid and are of three sizes, numbered 4, 7, and 9, being respectively $\frac{4}{32}$, $\frac{7}{32}$, and $\frac{9}{32}$ of an inch in diameter. The sailors on the vessel, with the shot line that has been sent them, haul off an endless rope, rove through a tail-block, called the whip line. If the masts are standing, the tail-block is made fast to the lower mast, well up. The life-saving crew then send off by the whip a 3-inch hawser which is secured to the mast about 2 feet above the tailblock. By means of a strong tackle attached to a sand anchor, consisting of two pieces of flat, stout timber, crossed and bolted, and buried in a trench to support the strain, the surfmen set taut the hawser, passing it over a wooden crotch about 10 feet high which firmly suspends the line between ship and shore. The breeches-buoy block is usually snapped upon the hawser, and the buoy is hauled to and from the wreck with the whip line. Small wooden tablets called tally boards, bearing printed directions in English and French for handling the lines, are attached to the whip and hawser and sent off to the people on the vessel to enable them to coöperate intelligently with the agencies at work for their rescue. In the usual drills at the stations the life-saving crews accomplish the rescue in about five minutes, although it has been made without error in two and one-half minutes. Of course such time cannot be expected in actual service at shipwrecks, where many unfavorable elements conspire to obstruct progress.



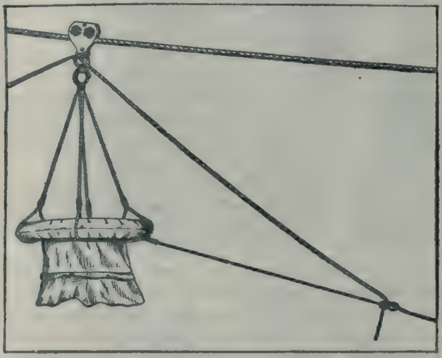
METHOD OF FAKING THE SHOT LINE.



WHIP-LINE TAIL BLOCK AND TALLY BOARD.

The survivors from a wreck within scope of the service are cared for at the station nearest the scene of the occurrence. The victims of marine disaster are often recovered from the water apparently drowned or dead from exposure. In such cases the surfmen attempt restoration by the methods in which they are drilled, their efforts in about half the trials turning out successfully.

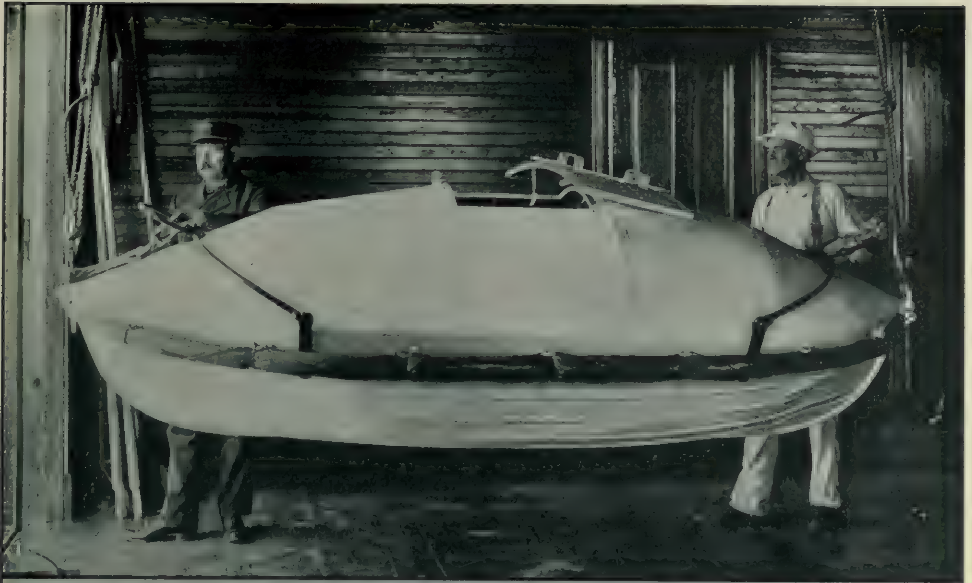
The Life-Saving Service, owing to its relation to commerce, and the assistance it renders in the collection of revenue and the prevention of smuggling, is connected with the Treasury Department. The chief officer in charge is the general superintendent, appointed by the President, the incumbent in 1914 being Sumner I. Kimball, who has been the head of the service since it was established in 1871. The general superintendent is assisted in the performance of his duties by an assistant general superintendent. A captain of the Revenue Cutter Service is detailed as inspector of stations. He personally visits them at stated times and discharges such other duties as the general superintendent directs. The superintendents of construction of life-saving stations are also captains of the Revenue Cutter Service. Each district is under the immediate charge of a superintendent who has been promoted to his position from the ranks of the keepers. His business is to conduct the general affairs of the stations under his supervision, which he visits at least once a quarter, recommend supplies, repairs, etc., pay off the men, inspect public property, fix the patrol limits, after consultation with the resident inspector, certify the names of eligibles for vacancies in the crews, and see that the regulations governing drills and discipline are faithfully fulfilled. The district superintendents and keepers are, under the law, inspectors of customs and as such take care of the government interests in relation to dutiable property wrecked within their jurisdiction. Assistant inspectors for the various districts are obtained from the officers of the Revenue Cutter Service, who periodically inspect the stations, drill the crews, make investigations into the conduct of keepers and surfmen, when such action is necessary, and in cases of shipwreck within the domain of life-saving operations attended with loss of life, and give attention to such other matters as may be assigned them by superior authority.

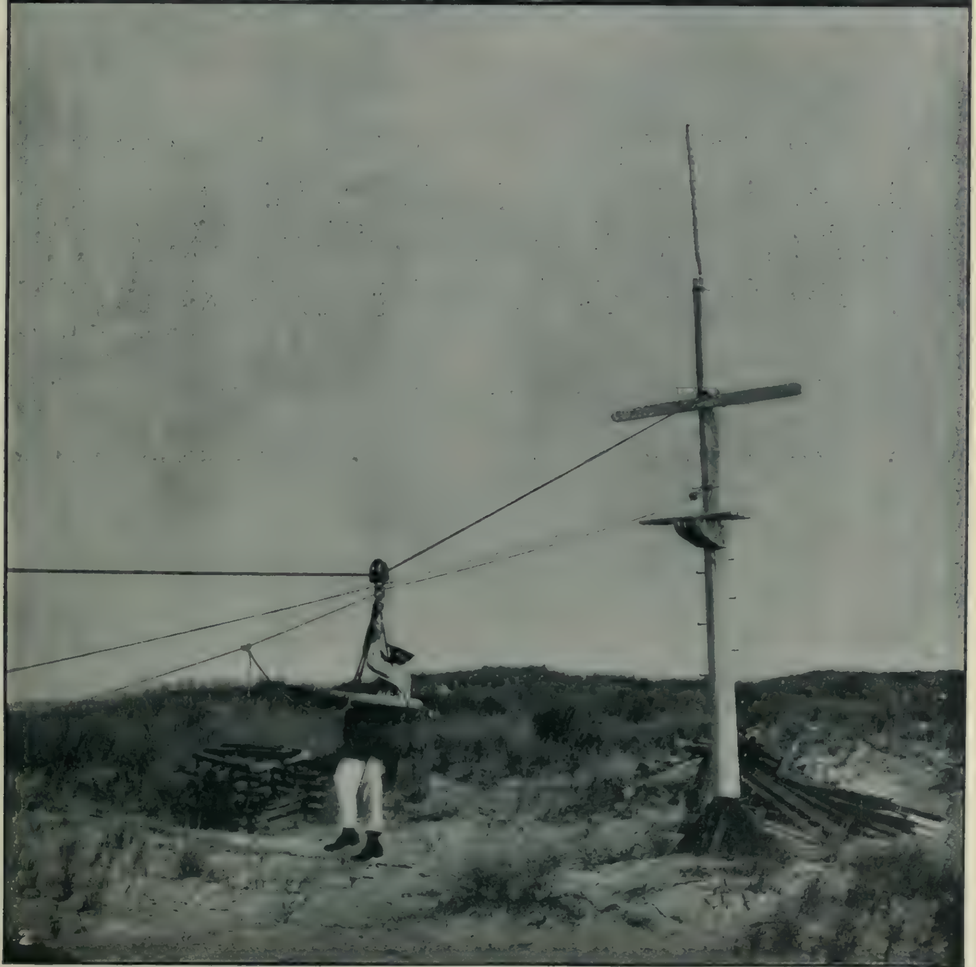


THE BREECHES BUOY.

For the purpose of examining and testing devices, plans, and inventions for the improvement of station equipments, an advisory board is constituted, consisting of experts, which meets annually, as a rule, to consider matters submitted to it by the general superintendent.

Members of crews, including keepers, who become disabled in the line of duty may be continued on the rolls of the service, under pay,

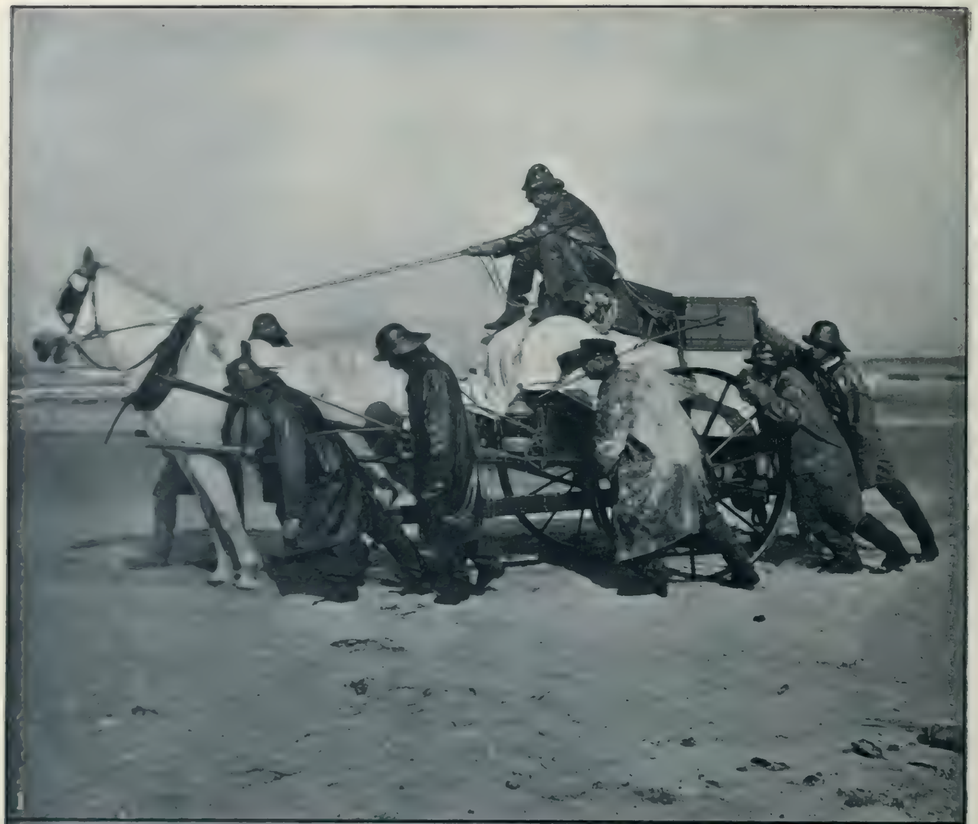


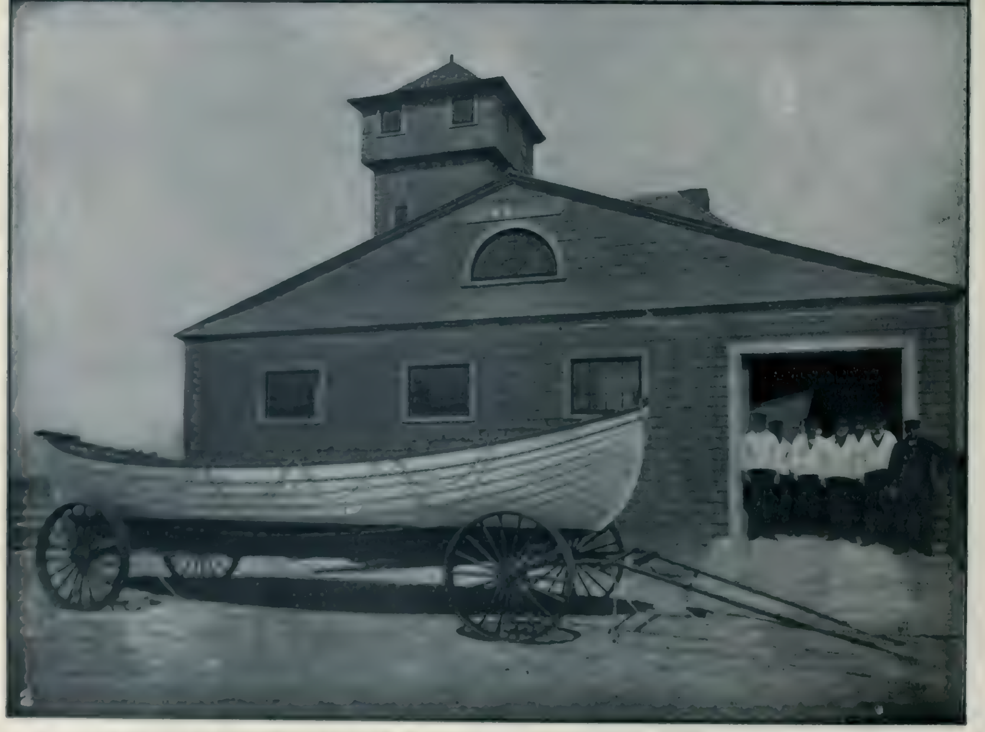


1. THE LIFE-CAR

2. DRILL WITH THE BREECHES BUOY

UNITED STATES COAST GUARD





1 UNITED STATES COAST GUARD CREW AND BEACH APPARATUS EQUIPMENT

2 BEEBE McCLELLAN SURFBOAT ON ITS WAGON. This type of boat is propelled by oars. A typical Coast Guard station is also shown

during the continuance of their disability, not to exceed one year, except in the most meritorious cases, but not longer than two years in any case. In case of their death, from disease or other cause incident to the service, their widows and children under 16 years of age, if they have any, are entitled to receive for two years, in equal portions, the same pay that the husbands or fathers would have received had they lived.

Gold and silver medals are awarded in cases of heroism, where persons endanger their own lives in rescuing or endeavoring to rescue lives from the perils of the sea. These rewards, however, are not confined to the professional life-savers, but may be bestowed upon others who have shown conspicuous heroism on such occasions.

The general superintendent, in accordance with the requirements of an act of Congress, publishes annually a complete report of life-saving operations. Incorporated in this is also a collection of statistics of marine disasters, at home and abroad, put in tabular form for convenient reference, which is of great value to commerce. The net cost of maintaining the service during the fiscal year ending June 30, 1914, was $2,309,317.41. The results of service operations for the same period are as follows:

Number of disasters	1,937
Value of property involved	$21,507,860
Value of property saved	$18,783,200
Value of property lost	$2,724,660
Number of persons involved	9,296
Number of persons lost	38
Number of persons succored at stations	920
Number of days succor afforded	1,234
Number of vessels totally lost	82

EUROPEAN AND OTHER LIFE-SAVING SERVICES

In nearly all maritime countries some organized means exist for assisting the shipwrecked from the shore. These means, with few exceptions, are controlled and supported either wholly or in part by private institutions. China for centuries has had a life-saving service, operated by benevolent societies, which has been mainly directed to rendering aid and preventing casualties on the great waterways of the Empire. The following summary embraces the principal efforts in this direction that have been made in European countries:

Austria. The conditions on the east coast of the Adriatic do not render necessary the maintenance of a regular life-saving service. In case of shipwreck or other marine casualty the health officers of the port or harbor police are required to give the first aid to those in danger and to relieve and take charge of vessels and cargoes. Specially constructed lifeboats, ready for immediate use, are stationed for this purpose at a number of the ports, while steamers and other boats are employed in emergencies.

Belgium. A small service, which was organized in 1838, is maintained by the government. Life-saving stations are scattered along the coast, over an extent of about 400 miles, and these are provided with lifeboats, completely equipped, wreck guns and projectiles, and other apparatus for assisting crews and vessels in distress. The appliances are kept in sheds situated at places accessible to the beach. Medicines and surgical implements are also supplied, a physician being appointed to care for shipwrecked crews.

Denmark. The institutions for the rescue of the shipwrecked are those of North Jutland, Bornholm, and Möen, the expenses of which are defrayed by the government. The service was organized in 1852, but means for the relief of distressed seamen were adopted at certain points on the coast before that time. Lifeboats and rocket apparatus are used and the work is performed by overseers and boatmen, there being some 50 or more stations and substations on the coast of Jutland, where the principal efforts for saving life are directed.

France. The task of maritime life-saving is performed by the Société Centrale de Sauvetage des Naufragés, which was founded in 1865. The organization is somewhat similar to that of Great Britain and is supported mainly by voluntary contributions, the government granting some financial aid. The society has between 400 and 500 stations on the coasts of France and Algeria, and employs more than 2000 persons, most of whom, however, are in the customs service. About one-fifth of the stations are provided with lifeboats. Unlike most of the European services, the French use the gun in preference to the rocket for effecting line communication with vessels, and the statement is made that to M. Ducarne de Blangy should be attributed the credit of having first invented a line-carrying projectile in 1790.

Germany. The entire life-saving service is under the management of the German Society for the Rescue of the Shipwrecked, which was founded in 1865. It is under the patronage of the Emperor and is wholly supported by voluntary contributions, there being more than 100 stations on the coasts of the Baltic and North Sea. About half of them are equipped with both boats and rocket apparatus, the others having boats or rockets only.

Great Britain. Life-saving operations are conducted by the Royal National Lifeboat Institution, which was established in 1824. This organization, which is aided by various local corporations and private parties, provides lifeboats and apparatus for the whole English coast. There were in 1914 274 lifeboat stations under its management. Except a coxswain and an assistant for each boat, who receive annual salaries, the boatmen are volunteers, who are paid for each occasion of service. The rocket service, which embraces a large number of stations, is in charge of the Board of Trade and was organized in 1855. Operations on wrecks are under the supervision of the Coast Guard, which patrols the coast. The English claim that Lieutenant Bell, of the Royal Artillery, first invented, in 1791, a method for projecting a line to a vessel from the shore.

Holland. Two private companies carry on the life-saving operations—one at Amsterdam and the other with headquarters at Rotterdam. The former, which appears to be the more important, is supported by donations from private sources, no assistance being received from the government. The exertions of the company are confined exclusively to the saving of imperiled persons, about 25 stations, provided with lifeboats, being maintained. Fifteen of these have rocket apparatus also.

Italy. The principal life-saving institution is the Società Italiana per provvedere al Soccorso dei Naufraghi, which has its central offices in Rome. It maintains eight lifeboat and two rocket stations. There are besides a number of local societies for alleviating the miseries of the shipwrecked or for resuscitating persons apparently drowned. One of these, the Società Ligure di Salvamento, has 46 huts of refuge.

Russia. The work of rendering assistance to persons in distress on the seas, lakes, and rivers is directed by a society established under the patronage of her Majesty the Empress. It is supported mainly by private benefactions. The business of the society is managed by a principal board located at Petrograd and by a number of district and local boards in various towns and villages. The stations number nearly 1000 of all kinds, including boat and rocket stations, winter stations, substations, places of refuge, lighthouses, posts, etc. The compensation of the life-saving men is determined by the district boards, some of the keepers and crews being paid annual salaries, while others receive remuneration for service and drill only.

Spain. The Spanish Society for Saving the Shipwrecked, with a central board in Madrid, which was reorganized in 1880, has charge of the life-saving service. It receives both government and private gratuities. Its object is to save lives only. Some 50 stations are supported, supplied with boats, line-throwing apparatus, etc., while life-saving appliances of various kinds are kept at many of the lighthouses.

Canada. The Life-Saving Service of Canada was established in 1880 and is supported by the government. The present organization, methods, and equipment are patterned from the United States Life-Saving Service. There were in 1915 between 40 and 50 equipped stations.

Japan. The National Lifeboat Institution of Japan is a voluntary society receiving government assistance. The society was founded in 1889 and is managed by a president, vice president, and council.

Lifeboat and apparatus service is rendered also in the following-named countries by voluntary associations: Turkey, established in 1868; Portugal, established in 1898; Norway, established in 1891; India (east coast); New Zealand; Australia (South). See SAFETY AT SEA.

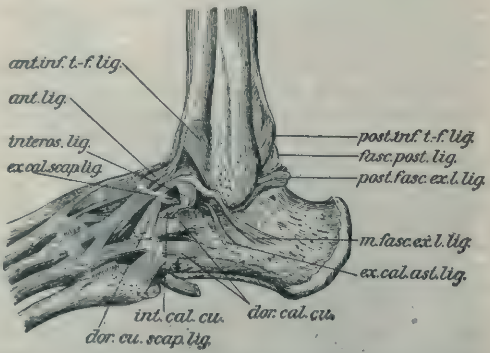
LIFFEY, lĕf′ĭ. A river of Leinster, Ireland, rising in the Wicklow Mountains, 12 miles southwest of Dublin (Map: Ireland, E 5). After a semicircular course of 70 miles, south, west, and northeast, it divides the city of Dublin (q.v.) in two and flows into Dublin Bay on the Irish Sea.

LIG′AMENT (Lat. *ligamentum*, band, from *ligare*, to bind). A cord, band, or membranous expansion of fibrous tissue passing in a fixed direction from one bone to another and serving to limit and control the movements of joints. Ligaments are divided into three classes: (1) *capsular* (Lat. *capsula*, a small box); (2) *fascicular* (Lat. *fascis*, a bundle); and (3) *funicular* (Lat. *funis*, a rope). 1. Capsular ligaments are cylindrical expansions which are attached by their extremities around the margins of the articulating surfaces composing the joint. 2. Fascicular ligaments are flattened bands of various shapes and widths. 3. Funicular ligaments are round on section, and shaped like a heavy cord, as the *ligamentum teres* of the hip joint.

Two ligaments in the body, the *ligamentum subflava* and the *ligamentum nuchæ*, both of which are connected with the spinal column, are composed of yellow elastic tissue. All other ligaments in the body are composed of white fibrous tissue.

The various ligaments result from metamorphosis and retrogression of muscle tissue, with but few exceptions. In a few cases ligaments represent the degenerate remains of cartilage or bone. Capsular ligaments are derived from the periosteum, and are strengthened by the incorporation of tendons of adjacent muscles.

The term "migration of muscles" is applied in myology to an alteration of a point of attachment of a muscle, occurring during tissue changes in low vertebrate forms, whereby a point of origin of a muscle shifts from a position below a joint, e.g., to a position above the joint. The former position of the muscle end is occupied by a ligament under which form part of the muscle tissue persists. An excellent example is the external lateral ligament of the knee joint, which represents the tendon of the *peroneus longus*, this muscle having migrated from the femur to the head of the fibula. See JOINTS. Consult Cunningham, *Text-Book of Anatomy* (New York, 1913).



EXTERNAL VIEW OF THE LIGAMENTS OF THE FOOT AND ANKLE.

Ant.inf.t.-f.lig., antero-inferior tibio-fibular ligament; *ant.lig.*, anterior ligament of ankle joint; *interos.lig.*, outer extremity of the interosseous ligament; *ex.cal.scap.lig.*, external calcaneo-scaphoid ligament; *post.inf.t.-f.lig.*, postero-inferior tibio-fibular ligament; *fasc.post.lig.*, fasciculus of posterior ligament of ankle; *post.fasc.ex.l.lig.*, posterior fasciculus of external lateral ligament; *m.fasc.ex.l.lig.*, middle fasciculus of external lateral ligament of ankle; *ex.cal.ast.lig.*, external calcaneo-astragaloid ligament; *dor.cu.scap.lig.*, dorsal cubo-scaphoid ligament; *int.cal.cu.*, internal calcaneo-cuboid; *dor.cal.cu.*, dorsal calcaneo-cuboid.

LIGAMENT, IN COMPARATIVE ANATOMY. The presence of true ligaments among invertebrates is doubtful, unless we include under the term all strands of connective tissue which serve to bind one part to another, such as that in the hinge of bivalved mollusks. This band is composed of two layers, of which the inner is very elastic, and has somewhat the appearance of cartilage. See PELECYPODA.

Among vertebrates ligaments are found of great variety of form and function, especially among birds and mammals. Of these, one which is but slightly developed in man, though largely developed in the gorilla, deserves a brief description. This is the *ligamentum nuchæ* or neck ligament, which assists in the support of the head in long-necked ungulates, as the horse, camel, and ox. It is composed of yellow, elastic, fibrous tissue and is associated with a remarkable development of the neural spines of the anterior thoracic vertebræ, to which its posterior end is attached. The anterior end is connected with the base of the skull and some of the anterior cervical vertebræ. This ligament is well known to butchers, by whom it is called paxwax or faxwax. A similar ligament is present in most other mammals, but does not reach such a high development. The ligament whose function it is to operate the elevated sheathed claws of cats will be found explained and illustrated under Cat.

LIGAMENTUM NUCHÆ. See Neck.

LI′GAN, or LA′GAN. In English and American law, goods cast overboard to lighten a ship in danger of destruction by storm or of capture by pirates and which are attached to a buoy so as to make recovery possible. Such goods are not technically wreck and so do not fall within the operation of the peculiar rule which, under certain circumstances, involved a forfeiture of wrecked property to the crown. See Flotsam; Jetsam; Wreck.

LIGAO, lē-gä′ō. A town of Luzon, Philippines, in the Province of Albay (Map: Philippine Islands, D 4). It is situated on the main road of the province, about 22 miles west-northwest of Albay, in the midst of a large hemp-growing district. Pop., 1903, 17,687.

LIG′ATURE (Lat. *ligatura*, band, from *ligare*, to bind). A thread of silk, catgut, or other material, tied around a blood vessel to arrest hemorrhage or to diminish the flow of blood to an aneurism or tumor. While a distinction is made between ligature and suture, the latter term designating strands used for sewing or stitching, the same materials are employed for both purposes. The use of ligatures was known many centuries ago, the old Roman surgeons using them with considerable skill. During the Dark Ages they were forgotten, and it was not until Ambroise Paré (q.v.) introduced them (about 1536), while in Italy with the army of René de Mont-Jean, that their use was slowly revived. Up to this time hemorrhage from wounds was stopped by searing them with red-hot irons or plunging the part in hot pitch. John Hunter, an English surgeon, first advocated the ligature in the treatment of aneurisms by tying off the artery at some distance from the aneurismal sac. The materials from which ligatures have been made are very numerous. Those in most common use are silk, catgut, and silkworm gut, but kangaroo tendon, linen, hemp, ox aorta, horsehair, dentists' floss, fine wire, and other materials are utilized. Catgut, like most animal substances, is quickly absorbed by the tissues and is used for buried ligatures. Silk is not absorbed, but has the advantage of being much stronger than catgut (and therefore more suitable for delicate work) and more easily sterilized. Silver wire is useful where considerable masses of tissue have to be included in the ligation.

Ligatures are employed for arresting hemorrhage in arteries or veins either at the time of an amputation or other operation in which a vessel is divided, or when an artery is wounded accidentally; for removing tumors of various kinds such as hemorrhoids; for diminishing the supply of blood to a part, as in the case of inoperable malignant tumors, whose growth may be sometimes temporarily arrested by cutting off their circulation, and for bringing about a cessation of blood flow through an aneurism.

The usefulness of the ligature depends upon the fact that when the internal coat of an artery is torn off or injured, the blood clots, the fluidity of the blood depending upon the integrity of this coat. Ligatures are therefore applied with sufficient force to rupture the internal and middle coats and constrict firmly the outer coat of the artery. Clotting takes place as far as the nearest branch, and this portion of the vessel is ultimately converted into a fibrous cord. Injured arteries of any size are tied on both sides of the wound to prevent possible recurrent hemorrhage from connecting branches. When the injured point is not accessible the ligature is sometimes placed at a distance from the wound.

In the treatment of aneurisms, the ligature is placed upon the artery, when possible, between the heart and the sac, and at some distance from the aneurism, for the reason that the artery in the vicinity of the aneurism is too diseased to resist being cut through by a ligature. This operation was devised by Hunter. Brasdor afterward conceived the idea of tying on the distal side of the aneurism; a barrier to the blood current is just as effectively formed, collateral branches above the aneurism enlarge, the blood is diverted and a clot forms in the aneurismal sac. Another device is that of Wardrop, which consists in tying one of the branches of the artery below the aneurism.

The important operations in arterial ligature are those involving the subclavian, innominate, carotid, and iliac arteries, and the abdominal aorta. The latter vessel has been tied on nine or ten occasions and the operation has always resulted fatally. It was first performed by Sir Astley Cooper in 1817, the patient surviving 48 hours; in 1902 a case operated on by Keen, an American surgeon, survived 48 days. These operations are done only in cases of desperate need, either in the event of an aneurism about to rupture or alarming hemorrhage from penetrating wounds. See Aneurism; Circulation; Brasdor's Operation.

LIGATURE. In music, a slur or tie, hence a term which indicates that a group or series of notes is to be executed coherently; if in vocal music, that they are to be sung with one breath. The term is used in instrumental music to mark the phrasing. In mensurable music ligature denotes a group of notes that are to be executed on one syllable. See Mensurable Music.

LIGER. See Loire.

LIGHT (AS. *lēoht*, Goth. *liuhap*, OHG. *lioht*, Ger. *Licht;* connected with Lat. *lucere*, to be bright, Gk. λευκός, *leukos*, bright, Ir. *loche*, lightning, OChurch Slav. *lucha*, beam of light, Skt. *ruc*, to shine). The sensation of which one becomes conscious through the optic nerves. In general the cause of this sensation is the entrance into the eye of ether waves whose wave numbers lie between certain limits; and therefore such unscientific expressions as "light enters the eye," "light waves," etc., are often used. From the standpoint of physics one is concerned with the problem of the production of these ether waves, their propagation and their entrance into the eye; after reaching the retina their further action becomes the study of physiology.

Any proper physical explanation of light must show that all the phenomena of ether waves both in the pure ether and inside material bodies may be deduced from certain dynamical equations, and with our present knowledge of matter and the ether this can be done with a fair degree of satisfaction. There are, however, many phenomena which do not require for the explanation of their main features any exact knowledge of the properties of ether and matter, but which may be referred to certain general mechanical principles. Thus, the most important phenomena of interference and diffraction may be explained by the general principles of wave motion; and the most striking features of lenses, mirrors, and prisms may be shown to follow from the treatment of rays of light, assuming the laws for reflection and refraction of rays.

That portion of the subject of light which may be explained by the use of the idea of rays is called Geometrical Optics; that portion which uses the idea of wave motion is called Physical Optics; and the complete treatment which explains the laws of rays and of waves and connects all the phenomena of dispersion, reflection, magnetic rotation, etc., by one set of dynamical equations is called the Dynamical Theory of Light.

HISTORICAL SKETCH

Geometrical optics is not entirely a modern science, for the Greeks and their disciples the Arabs were acquainted with the law of reflection and its more immediate consequences. Aristotle, Euclid, Archimedes, Hero, and Ptolemy knew that light was transmitted in straight lines; but with the important exception of Aristotle and some of his followers the ancient philosophers believed that rays proceeded *from* the eye *to* the object, instead of in the contrary direction. Ptolemy was well acquainted with atmospheric refraction. Alhazen (early part of eleventh century) and Vitellio the Pole (1260) were almost the only students of this science during the Middle Ages, and their additions to it were unimportant. The lens, though known from early antiquity, was not applied as an aid to defective eyesight till after the time of Roger Bacon. Jansen, Metius, and Galileo separately invented the telescope (q.v.) about the beginning of the seventeenth century; and with it the last-mentioned philosopher (see GALILEO) made various important astronomical discoveries. Kepler, shortly after, gave the true theory of the telescope, explained the method of finding the focal length of lenses, and applied it to find the magnifying power of the telescope, besides pointing out the mode of constructing an instrument better adapted for astronomical purposes than that of Galileo; he also made some useful experiments on the nature of colors, and showed that images formed on the retina of the eye are inverted, a fact previously discovered by Maurolycus of Messina. From this period the science of optics steadily advanced through the labors of De Dominis, Snell (the discoverer of the law of refraction in 1621), Descartes, Fermat, Barrow, Mariotte, and Boyle. Up to the time of Newton it was generally believed that color was produced by refraction, but he showed by a beautiful series of experiments that refraction only separates the colors already existing in white light. In his hands the theory and construction of the telescope underwent many valuable improvements, and in 1672 the description of his reflecting telescope was submitted to the Royal Society. Gregory had constructed an instrument on similar principles some years before. About the same time Grimaldi made his interesting series of experiments on diffraction, and noticed the remarkable fact of the interference of one pencil of light with the action of another.

To explain the phenomenon of sharp shadows Newton advanced his corpuscular theory of light, the idea of which was that light is due to the emission of streams of fine particles from the source of light. To explain refraction on this theory it was necessary to assume that the velocity of light is less in air than in glass or water. Using this theory, Newton tried to explain diffraction and the colors of thin plates; but the hypotheses involved in the explanation were too involved to be satisfactory. The important services of the ingenious but eccentric Hooke cannot be easily stated in a few words, as he discovered a little of everything, completed nothing, and occupied himself to a large extent in combating faulty points in the theories of his contemporaries. It must not, however, be forgotten that he has as much right as Huygens to the credit of originating the undulatory theory, though Hooke made little more than a lucky guess, while Huygens gave a remarkable discussion of the application of the theory to reflection and refraction. Newton's corpuscular theory was, however, the accepted one until the work of Young and Fresnel. The double refraction of Iceland spar was discovered (1669) by Bartholin, and fully explained in 1690 by Huygens. The velocity of light was discovered by Roemer (1675), and in 1720 the aberration of the fixed stars and its cause were made known by Bradley, who likewise determined with accuracy the amount of atmospheric refraction. The fact that the two rays produced by Iceland spar were polarized was known to Huygens; but polarization by reflection was not known until discovered by Malus in 1808. The properties of polarization were then investigated by Brewster, Biot, and especially by Arago.

The proof that light is due to wave motion was first given by Dr. Thomas Young, who published his work on interference in 1801. The difficulty of accounting for polarization phenomena by the theory of waves was first met by Fresnel, who proposed the idea that the ether waves are transverse, and showed how this hypothesis perfectly explained the observations. It is to Fresnel also that we owe the explanation of rectilinear propagation and of diffraction. The attempt made by Fresnel to give a dynamical theory of light was not successful, although he did deduce formulæ for reflection, refraction, and total reflection which are in good accord with experiment. Green, Lord Kelvin, Helmholtz, Stokes, Rayleigh, and more recently Poincaré, Larmor, and Lorentz, have advanced dynamical theories with more or less success; the theory of Lorentz based on the motion of electrons is most satisfactory.

GEOMETRICAL OPTICS

It is assumed in this subject—as the result either of direct experiments or of deduction from physical optics—that rays of light pass in straight lines through any homogeneous medium; that they are independent of each other; that when a ray meets a surface separating two transparent material media, e.g., water and air, it produces a reflected ray back into the first medium and a refracted ray in the second medium, the two having definite directions given by the laws of reflection and refraction. The laws of reflection are: If a tangent plane is drawn to the separating surface at the point where the ray strikes, the line perpendicular to this plane at the point bisects the angle between the incident and reflected rays and lies in the plane which includes them. The laws of ordinary refraction are: If a tangent plane is drawn to the separating surface at the point where the ray strikes and if a perpendicular line to this plane is drawn through this point, it will lie in the plane including the incident and refracted rays; and if the angles between these rays and the perpendicular line are θ_1 and θ_2, the ratio of sin θ_1 to sin θ_2 is a constant for the two media for a given kind of light. This ratio is called the index of refraction of the second medium with reference to the first; it is found to vary for light of different colors. If the first medium is the pure ether, this ratio is called the index of refraction of the second medium.

There are certain bodies—either crystal or isotropic bodies in a state of strain—such that when an incident ray falls upon them, not one but in general *two* refracted rays are produced. This is called double refraction. In one class of bodies one of the refracted rays obeys the ordinary laws of refraction and is called the ordinary ray, while the other ray does not in general do so and is called the extraordinary ray. In other bodies neither of the refracted rays obeys the ordinary laws in general. The main features of bodies of the former class, e.g., Iceland spar, were fully explained by Huygens on the wave theory, while those of the latter class, e.g., aragonite, were explained similarly by Fresnel. See section on *Physical Optics* below.

Shadows. If rays pass in straight lines, the main phenomena of shadows are at once explained. A small source of light, a point source, will cast sharp shadows of any opaque object which stops the rays. If the source of light is large, like a window, there will be certain points in the shadow of an opaque object, close to the object, which are not reached by any rays, there will also be points which are reached by rays from part of the source only, and then there will be points which receive rays from the whole source. Those points which do not receive any rays lie in the umbra or shadow proper, while those which receive rays from only a portion of the source lie in the penumbra. Thus, an eclipse of the sun by the moon is *total* at a point of the earth's surface which passes through the shadow cast out into space by the moon obscuring the sun's rays; it is called *partial* at a point on the earth if that point passes through the penumbra only; it is called *annular* if at any time during the eclipse there can be seen a ring of the sun's surface extending past the moon's disk. Pinhole photography is another phenomenon which follows at once from the passage of rays in straight lines.

Reflection. If rays from a point source fall upon a reflecting surface, each ray individually will obey the laws of reflection. If the incident rays form a small solid cone symmetrical about the line drawn through the point source and perpendicular to the surface, they are said to form a homocentric pencil; if, however, the axis of the cone of rays is oblique to the surface, it is called an astigmatic pencil. The rays forming a homocentric pencil after reflection form another such pencil, i.e., they either *converge* to a point on the perpendicular to the surface or *diverge* in such a manner that if the rays be produced back of the surface they will meet in a point on the perpendicular to the surface. This vertex of the cone of reflected rays is called the focus or image of the point source: it is a real focus or image in the former of the above cases; virtual, in the latter. The rays forming an astigmatic pencil after reflection do not in general have a point focus or image, but have as foci two short straight lines at right angles to each other and a short distance apart: they are called focal lines, and may be either real or virtual. A few special cases will be discussed briefly.

Plane Surface.—Let *PM* be the section made by the paper of a plane surface perpendicular to the paper; let *O* be the point source; *OMO'*, the perpendicular dropped from *O* upon the surface; *OP*, any incident ray; *PQ*, the reflected ray; *SP*, a perpendicular to the surface at *P*; *PO'*, the continuation of *QP* backward. By the laws of reflection the angles *OPS* and *QPS* are equal. Therefore by the laws of geometry the point *O'* is at a distance *O'M* back of the surface equal to that of the point *O* in front of it; and further the position of *O'* is entirely independent of the direction of the ray *OP*, and is therefore the same for all rays. Consequently, all rays diverging from *O*, both homocentric and astigmatic pencils, proceed after reflection at the surface as if they had come originally from the direction of *O'*. *O'* is therefore the virtual image of *O*. Similarly if an extended object is emitting light towards a plane mirror each point of the object will have a virtual image in the surface at the same distance behind it as it itself is in front of the surface. There will thus be a virtual image of the object of the same size.

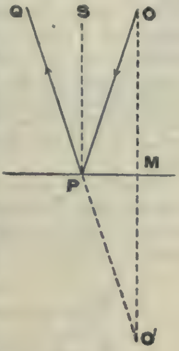


FIG. 1.

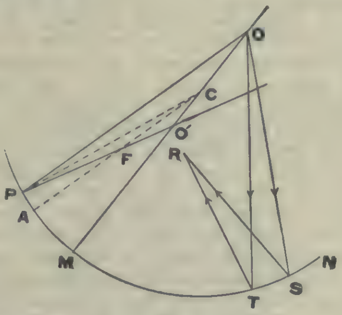

FIG. 2.

Spherical Surface.—Let *PMN* be the section made by the paper of the concave spherical surface; *O*, the point source of light; *C*, the centre of the sphere of which the surface is part; *OCM*, the perpendicular to the mirror (i.e., the axis for the point *O*); *OP*, any ray of a homocentric pencil; *CP*, the radius of the sphere drawn to *P*, and therefore perpendicular to the surface at *P*; *PFO'*, the reflected ray; *CFA*, a line drawn through *C* parallel to the ray *OP*. By the laws of reflection the angles *OPC* and *O'PC* are equal; then by ordinary laws of geometry the point *F* where the reflected ray O'_2P intersects the radius *CA* divides this radius in two equal parts, and the position of the point *O'* on the line *OCM* is independent of the incident ray provided that *P* is near *M*. Therefore all the rays of a homocentric pencil from *O* form another homocentric pencil on reflection with its vertex at *O'*: this point is therefore a real focus or image of *O*. If the distances *OM*, *O'M*, *CM*, are called u, v, r respectively, they are connected by the formula

$$\frac{1}{u}+\frac{1}{v}=\frac{2}{r}.$$

This formula can be shown to apply to any position of the point O and to either a concave or a convex mirror, provided only that the pencil of rays is homocentric.

Let OS and OT be two rays of an astigmatic pencil, and let SR and TR be their reflected rays. They intersect in a point R not on the axis. If a small pencil of rays is considered as falling on an elementary area of the mirror near T and S, the reflected rays will combine to produce a line perpendicular to the paper at R and another line lying in the paper across the axis; these are the two focal lines, real in this case.

If all the rays falling on the whole concave mirror are considered, they will form by reflection a bright point at the focus O', which is the apex of a bright curved surface made up of the focal lines such as was produced at R owing to an elementary area of the mirror. This pointed surface is called the caustic surface. A section of such a caustic formed by reflection at a cylindrical mirror is often seen on the surface of a glass of milk or a cup of coffee. The fact that astigmatic pencils do not bring the rays to the same focus as that of the homocentric pencil is said to be due to spherical aberration.

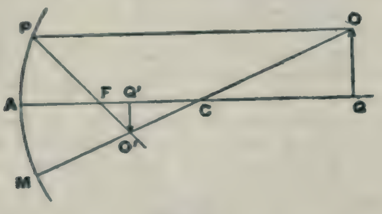

Fig. 3.

If any small object OQ is placed in front of a concave mirror, as shown, its image will be $O'Q'$, as is evident from the figure. The image is therefore real, inverted, and diminished in size, if the object itself is further from the mirror than the centre C. If the object is between the mirror and its principal focus F (which lies halfway from the centre to the mirror), the image is a magnified virtual one. The linear size of the image divided by that of the object equals $\frac{r-v}{u-r}$.

The case of a convex spherical mirror may be treated in the same manner, and the same formulæ will be found to apply, proper attention being given the algebraic signs of u and v.

Refraction. One must distinguish between homocentric and astigmatic pencils in refraction as well as in reflection; for a homocentric pencil of incident rays produces a homocentric pencil of refracted rays, thus giving a point focus, either real or virtual; and an astigmatic pencil produces, as before, two focal lines at right angles to each other. It should be observed, further, that the index of refraction—and hence the direction of the refracted rays and the positions of the foci—differs for different colors of the light. Light of a definite index of refraction is called light of a pure color, or homogeneous light. The indices of refraction with reference to air and for the mean wave length of white light are given for a few substances in the following table:

Alcohol, 1.36
Glass, soft, 1.52
Glass, hard, 1.66
Water, 1.34

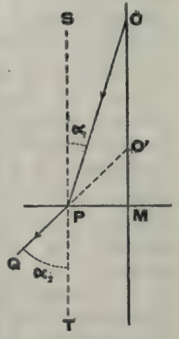

Fig. 4.

Several special cases of refraction will be considered.

Plane Surface.—Let PM be the section of the plane surface by the paper which is perpendicular to it; let O be a point source of homogeneous light forming a homocentric pencil, of which OP is one of the rays and OM is the axis; let PQ be the refracted ray; SPT be perpendicular to the surface at P; O' be the intersection of the line OM with the prolongation backward of the refracted ray. Call the angles SPO and TPQ α_1 and α_2 respectively. By the laws of refraction $\frac{\sin \alpha_1}{\sin \alpha_2}$ is a constant; call it n: then by ordinary geometry it can be proved that $O'M = nOM$. O' is therefore independent of the direction of the incident ray OP and is the vertex of the refracted homocentric pencil, being a virtual image of O. The diagram is drawn for a case where $n < 1$, e.g., rays emerging into the air from a bright point below the surface of water. If rays emerging from a bright point in air were entering water, $n > 1$ and O' is farther from the surface than O. If light of a different color had been used, i.e., of a different value for n, O' would have had a different position on the line OM. Thus, if light of different colors is emitted from O, there will be a series of colored images along OM. This fact that rays of different colors have different images is said to be due to chromatic aberration. Experiments show that in the case of air and glass, or air and water, blue light is refracted more than green, green more than yellow, yellow more than red; or, as a general statement, shorter waves are refracted more than longer ones.

A pencil of rays incident obliquely on the plane surface is astigmatic and has two virtual focal lines. If in the above diagram the incident ray OP is so oblique that the refracted ray PQ just grazes the surfaces, $\alpha_2 = 90°$, and therefore $\sin \alpha_2 = 1$. Hence $\sin \alpha_1 = n$, or $\alpha_1 = \sin^{-1} n$. If then there should be a ray more oblique than this value of α_1, it would be totally *reflected*, and there would be no refracted ray. This limiting value of the angle of incidence—$\sin^{-1} n$—beyond which all rays are totally reflected is called the *critical angle* for the two given media separated by the surface and for the particular kind of light for which the index of refraction is n.

Plate.—A portion of transparent matter bounded by two plane parallel faces forms a plate. A ray in passing through it from the medium on one side out into the same medium on the other side does not have its direction changed although the emerging ray is displaced sidewise.

Prism.—A portion of transparent matter part of whose bounding surface is two plane faces oblique to each other forms a prism. The line in which these two planes meet (or would meet if prolonged) is called the edge of the prism. Let the paper make a section of the prism perpendicular to its edge, as in the figure. Let the index of refraction of the material of the prism with reference to the surrounding medium be greater than 1; then the path of an incident ray *OP* will be as shown *OP* — *PQ* — *QR*, the angles of refraction being such as to satisfy the laws of refraction. The direction of the incident ray is *OPV*; that of the emerging ray, *WVQR*; so the change in direction, or the *deviation*, is the angle *PVW*. This deviation is a function of the index of refraction and therefore of the color of the light; so if there are two incident rays of different color along *OP* they will have different deviations and on emerging from the prism will be dispersed. It should be noted, however, that prisms of different material, e.g., different kinds of glass, disperse the same colors to different amounts; this is called irrationality of dispersion; and it is owing to this fact that achromatic lenses and prisms are possible. (See ACHROMATISM.) This phenomenon of dispersion may be expressed differently. If *O* is the source of a pencil of rays, it will have a virtual image owing to refraction at the first surface of the prism; the rays diverging from this image will have a virtual image owing to their refraction at the second surface; so the emerging rays will seem to come from a virtual source on the same side of the prism as *O*, the actual source. The position of this virtual source varies with the index of refraction of the rays; and different colors will have different virtual sources. So, if *O* is a source of rays of different colors, there will be a series of virtual sources, one for each color. If the prism is glass and the surrounding medium air, the virtual image of blue light will be closer to the edge of the prism than that of green light, and this is closer than that of red, referring to Fig. 5. This shows that the index of refraction *n* for glass with reference to air is greater for blue than for green, and the index for green greater than that for red.

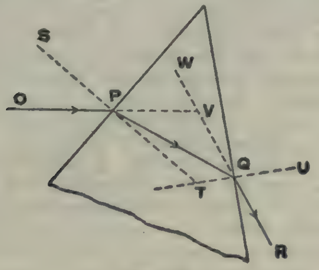

FIG. 5.

It should be noted that in the case shown in the figure, if *OP* is the central ray of a cone of rays, they form an astigmatic pencil; and so the virtual source is not really a point, but two focal lines. It may be proved that for one particular direction of the incident ray *OP*, these two focal lines, due to two refractions, cross at a point and thus give practically a point for the virtual source. This direction is such that the incident and emerging rays, *OP* and *QR*, make equal angles with their respective faces of the prism. For this ray, too, it may be shown that the deviation is less than for all the other rays from the source *O*; and it is called the angle of minimum deviation.

A prism offers one of the simplest and best methods for the measurement of the index of refraction with reference to air of a given material for definite colors. It may be proved that if *A* is the angle between the two faces of the prism and *D* the angle of minimum deviation for rays of a definite color—both measurable quantities—the index of refraction of the material of the prism for this color is given by the formula

$$n = \frac{\sin\frac{A+D}{2}}{\sin\frac{A}{2}}.$$

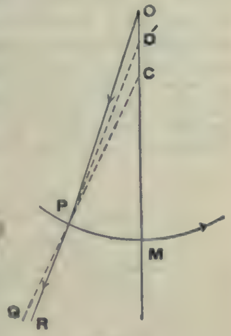

FIG. 6.

It is found for all ordinary transparent bodies such as different kinds of glass, water, etc., that as the color is changed from red to yellow, to green, to blue, etc., the index of refraction increases. In some bodies this is not so (e.g., green may be refracted less than yellow); they are said to exhibit anomalous dispersion.

Spherical Surfaces.—Let *PM* be the section of the spherical surface separating two transparent media; let *C* be the centre of this sphere; *O* be the source of a homocentric pencil, of which *OP* is one ray, and for which *n* is the index of refraction; let *CPQ* be a perpendicular to the surface at *P* and *PR* be the refracted ray, whose prolongation backward is *PO'*. As before, $\frac{\sin a_1}{\sin a_2} = n$, and by geometry it may be shown that *O'* is the virtual image of *O*, where *O'* lies on the line *OCM* which passes through the centre of the spherical surface, and the distance *O'M* is such that

$$\frac{n}{O'M} = \frac{1}{OM} + \frac{n-1}{CM}.$$

This same formula may be shown to apply to both convex and concave surfaces.

Lenses. A portion of transparent matter bounded by two spherical surfaces and symmetrical about the line joining their centres is called a lens; this line of symmetry is called the axis. A homocentric pencil of homogeneous rays from any point on the axis gives rise after two refractions to another homocentric pencil with its vertex on the axis. If the source of rays is *O*, at a distance *u* from a thin lens, the image *O'* will be at a distance *v* on the opposite side of the lens, where *u* and *v* are connected by the relation

$$\frac{1}{u} + \frac{1}{v} = \frac{1}{f},$$

f being a constant depending on the radii of the two surfaces of the lens and its index of refraction for the particular rays. *O* and *O'* are conjugate foci. If *O'* is the real image of *O*, then *O* will be the image of *O'* as a source of rays. (If in this formula, on substituting for *u* and *f* their values, *v* is a negative quantity, *O'* is on the same side of the lens as *O*.) There are two classes of lenses; for one, *f* is a positive number; and for the other, *f* is negative.

1. *f* is essentially positive.—As a special case let *O* be at an infinite distance, i.e., $u = \infty$ and all the rays from *O* are lines parallel to the axis. Therefore $v = f$, a positive quantity; and *O′* is on the opposite side of the lens at a distance *f*. This point is called the principal focus on that side; and all rays on the other side parallel to the axis pass through this focus after refraction through the lens; for this reason a lens of this kind is called a converging one. Similarly, if $u = f$, $v = \infty$; i.e., all rays passing through a point on the axis at a distance *f* from the lens emerge on the other side of the lens parallel to the axis. There are thus two principal foci at equal distances from the lens on its two sides. Again, any ray through the point where the axis cuts the lens has its direction unaltered, because at this point, which is called the centre of the lens, the two surfaces of the lens are parallel and close together, assuming that the lens is thin. These principles enable one to trace at least three rays leaving a point, and thus to find its image and to draw images for any point or for any object as formed by such a lens. Drawings are given for a few special cases:

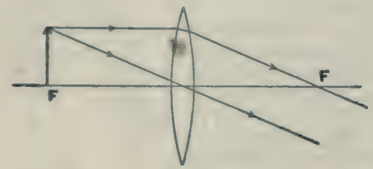

FIG. 7.

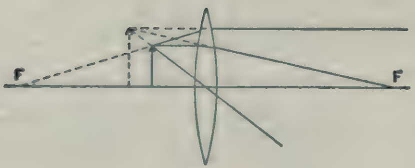

FIG. 8.

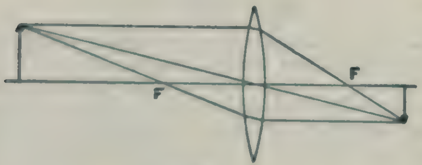

FIG. 9.

It is evident from the formula that if $u < f$, $v < 0$ and the image is virtual as shown in Fig. 8. In this case the image is magnified. The plane perpendicular to the axis at a principal focus is called a focal plane. If an object lies in this plane, as shown in Fig. 9, the image of each of its points lies off at infinity, as appears from the fact that the rays are parallel after leaving the lens. Conversely, parallel rays falling upon a lens for which *f* is positive converge after passing through the lens to that point in the focal plane through which passes that one of the parallel rays which cuts the lens at its middle point or centre.

2. *f* is essentially negative.—As a special case let *O* be at an infinite distance, i.e., $u = \infty$, and all the rays from *O* are lines parallel to the axis. Therefore $v = f$, a negative quantity; and *O′* is on the same side of the lens as *O* at a distance *f* from the lens. This point is called a principal focus; and there is evidently another one on the other side of the lens at the same distance from it. Therefore all rays parallel to the axis on one side of the lens *diverge* after passing through the lens as if from a point at a distance *f* from the lens on the same side as were the parallel rays. For this reason a lens of this kind is called a diverging one. Similarly a ray on one side of the lens pointed towards the principal focus on the farther side emerges from the lens parallel to the axis. Further, a ray through the centre of the lens remains parallel to itself. These principles enable one to trace at least three rays leaving a point not on the axis and thus to find its image, and to draw images of any object. Drawings are given of a few special cases:

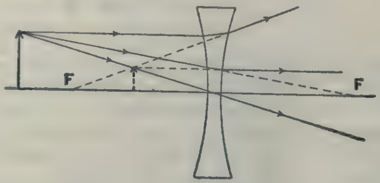

FIG. 10.

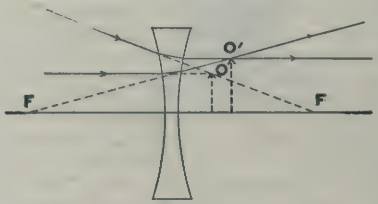

FIG. 11.

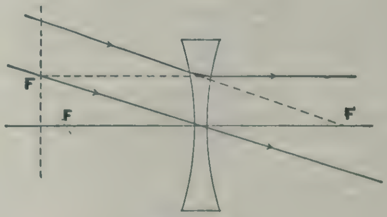

FIG. 12.

It is evident from the general formula that *v* will be positive, i.e., there will be a real image, if *u* is negative and numerically less than *f*, i.e., if *O* is on the opposite side of the lens from that on which the rays enter, and between the lens and the principal focus. This is the case when the entering rays are converging towards the point *O*, as shown in Fig. 11; under these conditions *O* would be called a virtual source. Again, as is seen from Fig. 12, parallel rays falling on the lens emerge as if coming from that point in the focal plane on the same side as that from which the rays come where the ray through the centre of the lens meets the plane.

If two thin lenses of focal lengths f_1 and f_2 are put close together with their axes coinciding, they form a lens whose focal length *f* is given by the formula

$$\frac{1}{f} = \frac{1}{f_1} + \frac{1}{f_2}.$$

If the two lenses are at a distance d apart, the focal length of the combination f is given by the formula

$$\frac{1}{f}=\frac{1}{f_1+d}+\frac{1}{f_2}.$$

If the lens is not thin, but so thick that this fact must be taken into account, it may be proved that there are two planes perpendicular to the axis, either in the lens or near it, which are so placed that if u is the distance from the source O to one plane and v that from the image O' to the other, the same formula as before applies. These planes are called the principal planes. They have other important properties also; but for a full discussion of thick lenses and their combination reference must be made to some treatise on optics.

Lenses and systems of lenses as used in microscopes, telescopes, photographic apparatus, etc., are subject to the following—among other—imperfections:

1. *Spherical Aberration.*—An oblique ray from a point on the axis does not pass through the same focus as does a homocentric pencil. See ABERRATION OF LIGHT.

2. *Curvature of Field.*—The image of a large plane figure perpendicular to the axis will not be formed on a plane but on a curved surface.

3. *Distortion.*—The image of a large object, e.g., a building, is not similar in all its parts to the parts of the object; the magnification may be different and a rectangular portion of the object may appear in the image with curved edges.

4. If the image of a small plane area perpendicular to the axis is formed by a lens which is large compared with the object, the image is not a small plane area perpendicular to the axis unless Abbe's sine formula is satisfied. If the system satisfies this condition, it is called *aplanatic*.

5. *Chromatic Aberration.*—Owing to the fact that the index of refraction differs with the color of the light, there are different focal lengths for rays of different color; and, further, if the lenses are thick, the magnification is different also. See ACHROMATISM.

Many of these imperfections can be avoided by a suitable choice of material for the lenses, by proper curvature for the lens surface, and by using suitable combinations of lenses. Lens combinations which are free from certain errors are called by special names. A photographic lens free from distortion of field is called orthoscopic; one free from curvature of field and from chromatic and spherical aberrations is called anastigmatic; a microscopic objective free from secondary spectra of chromatic aberration and aplanatic for several colors, apochromatic.

Several facts should be borne in mind in regard to an optical combination: 1. The intrinsic brightness of any surface cannot be increased by any optical means. The natural brightness of any object—that is, the light received per square centimeter of the image on the retina of the eye when looking directly at the object—is as great as the brightness when looking at the object through a telescope or microscope. 2. The brightness of a star or point source may, however, be increased by using a telescope, because by means of it more light is brought into the eye; the increase is in general proportional to the ratio of the area of the object glass of the telescope to that of the iris of the eye. 3. No amount of magnification will enable one to resolve two point sources—i.e., to see them as two separate objects—if they are as close together as a certain fraction of the wave length of the light which they are emitting. This fact depends upon the properties of diffraction of the ether waves, and will be discussed later. For detailed description of various optical instruments, see the articles MICROSCOPE; TELESCOPE; SPECTROSCOPE; ETC.

PHYSICAL OPTICS

In this branch of light the assumption is made that the sensation called light is due to the reception into the eye of trains of waves. A source of light is, then, a source of waves which are propagated from the source to the eye—or to whatever instrument is used to detect their presence—and produce there certain effects. The phenomena to be considered are then (1) the fact that trains of waves carry energy; (2) the fact that waves are propagated with a finite velocity; (3) the kinematic properties of composition of wave motion.

Photometry (q.v.) is that division of light which is concerned directly with the comparison of quantities of light emitted by various sources and received by different bodies. If a point source emits in all directions a quantity of light M, its intensity is said to be $M/4\pi$, i.e., the quantity of light going out through a unit solid angle. This intensity is written I. A small surface of area A, at a distance r from the point source, and inclined to the line joining it to the point source so that the angle between this line and a line perpendicular to the surface is θ, receives therefore an amount of light $\frac{IA\cos\theta}{r^2}A$. The intensity of illumination of this surface is the amount of light per square centimeter; it is written E. Hence $E=\frac{I\cos\theta}{r^2}$. Therefore the illumination varies directly as the intensity of the light, inversely as the square of the distance, and as the cosine of the obliquity of the surface.

Velocity of Light. The fact that time is required for the propagation of whatever it is that causes light has been known since the observation of Roemer on the eclipses of Jupiter's satellites in 1675. It follows then—granting that light is due to wave motion—that there is a medium filling all interstellar space, which serves to convey these waves. This medium is called the ether (q.v.), and it is evident from the properties of transparent bodies that it permeates them, and may in fact be regarded as a universal medium. There is every reason, both theoretical and experimental, for believing that the velocity of waves of all lengths is the same in the pure ether, e.g., in interstellar space; but inside of ordinary matter the velocity of ether waves varies with the wave length, and of course their velocity is different in different media. It will be shown below under *Refraction* that the index of refraction of one medium with reference to another for a definite color is the ratio of the velocity in the second medium of these ether waves which correspond to that color to that of the same waves in the first medium. There are two experimental methods for the determination of the velocity of ether waves in air—or, as often expressed, the velocity of light in air. One depends upon the use of a toothed wheel, which is made to revolve rapidly in front of a source of light, thus allowing intermittent flashes of light to be seen through the teeth. These waves coming through the gaps between the teeth traverse a considerable distance—several miles—and fall upon a mirror which reflects them back in their original direction. If on their return to the wheel the latter has turned so far that they strike a tooth, they are stopped; if, however, the wheel has turned farther so that they find an opening between the teeth, they will pass through and their return may be observed by suitable means. If the speed of the wheel is thus exactly right, the waves passing out through one opening will return through the next; if the speed is now increased, the returning waves will be stopped by a tooth; if the speed is still further increased, the waves passing out through any one opening will return through the next but one, etc. Therefore, if the speed of the wheel, the size of the teeth, and the distance between the wheel and the mirror are known, the velocity of the waves may be calculated. This method is due to Fizeau and has been used by him, by Cornu, by Forbes and Young, and more recently by Perrotin. The other method consists in allowing light from a narrow slit to fall upon a mirror, be reflected to another distant mirror which reflects it back to the first mirror and thus back to the source. This first mirror is not stationary, however, but is made to revolve rapidly; so that, when the waves return from the distant mirror, the angles of incidence and reflection are not quite what they were before, and so the waves are not reflected directly back to the slit source, but are deflected slightly. If the amount of this deflection, the distance apart of the two mirrors, and the rate of revolution of the rotating mirror are known, the velocity of the waves may be calculated. This method is due in part to Fizeau also, but in the main to Foucault. It has been used by the latter, by Michelson, and by Newcomb. For several reasons this method is not so good as that of the toothed wheel. (See Cornu, *Reports of International Congress of Physics*, Paris, 1900, vol. ii, p. 225.) The accepted value for the velocity of light in air is 300,000 kilometers or 3×10^{10} centimeters per second, with a possible error of less than one part in 1000. This is about 186,600 miles per second. Foucault showed by direct experiment that the velocity of light in air is greater than that in water, an observation which definitely overthrows Newton's corpuscular theory of light.

Huygens's Principle. To show how the properties of rays, which were assumed as the basis of geometrical optics, are consequences of the propagation of ether waves, use must be made of a theorem in kinematics known as Huygens's principle. As a result of disturbances in any medium which can transmit wave motion there will be at any instant a definite wave front, *i.e.*, a surface which is the locus of all points just reached by the spreading waves; there will be no effect at any point ahead of the wave front until it is reached; but Huygens's principle asserts that we can predict what will be the effect at that point if we assume that each minute portion of the medium in the wave front is a centre of spherical waves. These spherical waves spreading out from each point of the wave front all start in the same phase; but, as they overlap and are superimposed at the point for which the effect is to be predicted, they will be in different phases depending upon the distances from this point to the various point sources. The entire effect at the point due to the compounding of these secondary waves is, in accordance with Huygens's principle, exactly the same as that due to the advance of the original wave front. This principle of Huygens has been perfected so as to give the proper amplitude and phase for the resulting motion, and serves as the basis for the explanation of all the purely optical phenomena of light. It will now be shown how this principle, combined with that of interference, explains the properties of rays.

Rectilinear Propagation. A point source of waves produces a spherical wave front in an isotropic medium, because the velocity is the same in all directions. Let O be such a point source of waves; NM the section by the paper of the spherical wave front at any instant; P is some point in front of the wave front; M is the intersection of the wave front by the line OP. When it is said that light travels in a straight line, it is equivalent to saying that if an opaque obstacle is placed with its edge at the point M its shadow will just include P. It can be shown that the principle of Huygens predicts that this statement is not quite accurate; and more careful experiments prove that the modifications suggested are observed. Instead of considering all the infinite spherical secondary waves, proceeding from the surface NM to P, the disturbances may be grouped together according to a manner devised by Fresnel. Call the distance PM a, and let the wave length of the waves be λ; then with P as a centre draw spherical surfaces of radii $a + \frac{\lambda}{2}$, $a + \lambda$, $a + \frac{3\lambda}{2}$, etc. These surfaces will intersect the spherical wave front in circles which will thus include zones between them, the distinguishing characteristic of a zone being that any point in it lies at such a distance from P that there are points in the two contiguous zones for which the distances to P differ from it by half a wave length. Consequently, if the combined effect of the action of all the secondary waves from the points of any one zone is to produce action in one direction, the resultant action due to both the neighboring zones is in the opposite direction. Let the numerical values of the effects at P due to the different zones be m_1, m_2, m_3, etc., for the first or central zone around M, the second, third, etc. The final numerical value of the action of the secondary waves is, therefore,

$$m_1 - m_2 + m_3 - m_4 + m_5 - \text{ etc.}$$

The value of m for any zone depends upon three things: the area of the zone, the distance of the

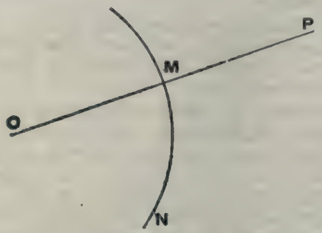

FIG. 13.

zone from P, and the inclination of the line joining P to the zone with the line PMO. It may be shown that owing to these causes the value of M for any zone is less than that for the one just inside; and, if the wave length is small, as it is in the case of ether waves (and also for the waves produced in air by very shrill sounds), this difference between the numerical values of the action for the zones is small. Under these conditions the above sum $m_1 - m_2 + m_3 -$ etc., reduces to simply $\frac{1}{2}m_1$. In words, the action at P owing to the secondary waves from any one zone is neutralized by that of the waves from one-half of each of the neighboring zones; and so the final action at P is one-half of that due to the secondary waves from the central zone around M, because in the case of a large wave front the effect of the outmost zone may be neglected. If the wave length is extremely small, as in ether waves, the areas of these zones are almost infinitesimal; but if the wave length is long, as in aërial waves, they have a sensible size. If the action of the central zone is blotted out by an opaque obstacle, the action at P due to the rest of the wave front spreading out from the source at O is $m_2 - m_3 + m_4 -$ etc., or $\frac{1}{2}m_2$, and is therefore hardly changed at all, if the zones are small. If the obstacle blots out two zones, the action at P is $\frac{1}{2}m_3$; etc. Consequently, if any small circular opaque disk is placed at M at right angles to the radius, there is always action at P, and its value is one-half that due to the first zone outside the edge of the disk. Naturally as a larger and larger disk is used the intensity of the action at P decreases. Similarly, if an opaque screen with a circular opening is placed at M, the effect at P depends upon the area of the opening. If this area is that of the first zone, the action at P is twice what it would be if the screen were entirely removed; if the area includes two zones, there is practically no action at P; etc.

If the opaque screen has zonal openings so as to expose only the odd zones, the effect at P is $m_1 + m_3 + m_5 +$ etc., and so is very intense. If this zone plate, so called, is modified so that the opaque rings are replaced by transparent rings of such a thickness as to introduce a difference of half a wave length by virtue of the fact that the velocity of light in the transparent material is less than in air, all the zones will conspire to help in the action at P. It is evident that the size of the zones varies with the color of the light; and if white light—or a mixture of colors—is coming from the source, passing either through a small circular opening or around a small circular disk, there will be colored effects near P. All of these effects with openings and disks are amply verified by experiments with both ether and aërial waves, the only difference coming from the fact that the aërial waves are as a rule many centimeters long, while the ones in the ether that affect our sight are about 0.00005 of a centimeter long.

If a large opaque screen ML is placed near a point source O, as in Fig. 14, rays drawn grazing its boundary form what is called the geometrical shadow. Thus, if OMP is one of these rays, the shadow lies on one side of it. The effect at a point Q just within the shadow can be found by considering the zones on the wave front around N, which correspond to Q. It is evident that there is an action at Q due to those zones which are not obscured by the obstacle. As points are taken farther and farther in the shadow, however, this effect becomes less and less, gradually fading away. (This explains why aërial waves pass around corners into the shadow, and asserts the same phenomena for ether waves, only to a much less distance, owing to the smallness of the zones in their case. This is actually observed.)

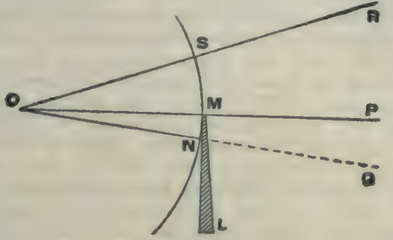

FIG. 14.

Similarly the action at a point R outside the shadow depends upon the number of zones drawn around S, the intersection of OR with the wave front, which are not obscured by the opaque obstacle. If R is very close to P, only the first zone may be uncovered, and the action is intense; but as R recedes from P the second zone begins to neutralize the action of the first, and so the intensity at R decreases; then, as R continues to recede, the action again increases, etc., until R is so far away from P that the action of the zones of high order makes no difference. Consequently, if homogeneous light is used, and a screen is placed to receive the shadow, there will be no sharp shadow, but the light will gradually fade away in the geometrical shadow, while outside this shadow there will be bright and dark bands following the general shape of the obstacle. These phenomena can be easily observed. If white light is used, these rings will be colored, because their position depends upon the wave length and so each color will have its own set of rings; but at a comparatively short distance from the edge of the geometrical shadow the effect is a uniform white illumination. These bands are called diffraction bands; and the whole phenomenon is said to be due to diffraction (q.v.), as is also that of the small disks and openings.

These diffraction rings or bands are seen most clearly if the opaque obstacle has a linear edge like a knife edge and if it is illuminated by light coming through a *slit* parallel to this edge; then, if the light is received on a screen suitably placed, the bands will be most distinct. Other cases of diffraction will be discussed later.

It thus appears that the sense in which light travels in straight lines is not in the casting of sharp shadows, for it does not, but in the fact that as ether waves spread out from a point source O, there being no obstacles, the effect at a point P is due entirely to the action of a minute portion of the wave front around M where the ray OP intersects it.

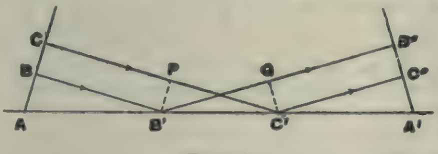

FIG. 15.

Laws of Reflection. It is not difficult to show that the laws of reflection are a direct consequence of the principle of the rectilinear propagation of light. Let $AB'C'A'$ be the section of a plane surface by the paper; draw the line ABC to represent the section of a plane by the paper, and similarly the line $A'C''B''$, making the angles CAA' and $C''A'A$ equal; draw the lines CC' and BB' perpendicular to the plane ABC and the lines $C'C''$ and $B'B''$ perpendicular to the plane $A'C''B''$; draw also $B'P$ perpendicular to CC' and $C'Q$ perpendicular to $B'B''$. If the plane $A'C''B''$ represents a wave front receding from the plane surface $AB'C'A'$, the actions at B'' and C'' are entirely due to those that were at B' and C' a short time previously; similarly, if the plane ABC represents an advancing wave front, the actions at B' and C' will be due to those now at the points B and C. Therefore if the time taken for the disturbance to pass from B to B' to B'' is the same as it is for the disturbance to pass from C to C' to C'', the receding wave front is due to the reflection at the surface $AB'C'A'$ of a wave front which was at ABC some time previously. But these times are the same because the lengths of the lines $CC'C''$ and $BB'B''$ are evidently equal by geometry, and the medium in which the disturbances are traveling is the same for both. Consequently the ray BB' is reflected into the ray $B'B''$; they make equal angles with a line drawn perpendicular to the surface at B' and these lines lie in one plane.

Laws of Refraction. In a similar manner the laws of refraction may be deduced. Let $AB'C'A'$ be the intersection of the paper with a plane surface separating two transparent media; let ABC represent the section of the paper with a plane in one medium, and $A'C''B''$ with a plane in the lower medium; draw BB' and CC' perpendicular to the former and $B'B''$ and $C'C''$ perpendicular to the latter, also $B'P$ perpendicular to CC' and $C'Q$ perpendicular to $B'B''$. If ABC is an advancing plane wave front, the action at B' is due to that at B, and at C' to that at C; and, if $A'C''B''$ is a receding wave front, the action at B'' is due to previous action at B' and that at C'' to previous action at C'. Therefore the wave front $A'C''B''$ will be that due to the refraction of the wave front ABC, provided the times taken for the disturbances to pass from B to B' to B'' and from C to C' to C'' are the same. This will be true if PC' bears the same ratio to $B'Q$ that the velocity of the waves in the first medium (v_1) does to that in the second (v_2). That is, the condition is that

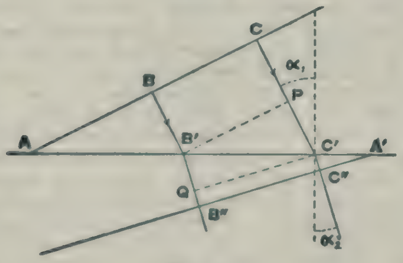

Fig. 16.

$$\frac{PC'}{B'Q} = \frac{v_1}{v_2}.$$

$$\text{But } PC' = B'C' \sin (C'B'P) \text{ and}$$

$$B'Q = B'C' \sin (B'C'Q)$$

and the angle $C'B'P = \alpha_1$, and the angle $B'C'Q = \alpha_2$. Hence the condition becomes

$$\frac{\sin \alpha_1}{\sin \alpha_2} = \frac{v_1}{v_2}.$$

The velocity of any homogeneous train of waves in any one medium is constant (but varies with the medium); therefore for any such train of waves $\frac{v_1}{v_2}$ is a constant and may be written n as before, the index of refraction of the second medium with reference to the first. Thus it is seen that the incident ray CC' becomes $C'C''$ by refraction, that they lie in a plane which includes the perpendicular to the surface at C', and that their angles of incidence and refraction are given by the formula $\frac{\sin \alpha_1}{\sin \alpha_2} = n$, where n is a constant for any one train of waves. Thus n, and therefore the velocity of ether waves, may be found to vary both for different colors in one medium and for the same color in different media. Since it has been shown that in ordinary matter n increases as the color is changed from red to yellow, to green, to blue, etc., it is evident that the velocity of those waves which produce the sensation red—red waves—is greater in ordinary matter than is the velocity of green waves, etc. For if the first medium is the pure ether and the second air (or glass, or water), v_1 remains constant for all waves, and if n increases it must be because v_2 decreases.

Double refraction is at once explained if the assumption is made that, whereas a point source in an isotropic medium produces a spherical wave point, in media which have different properties in different directions a point source produces a more complicated wave front. To explain the simpler case of double refraction, that where one ray obeys the ordinary laws of refraction, Huygens assumed that the wave front was a combination of a sphere and an ellipsoid of revolution, the axis of revolution being a diameter of the sphere. In bodies of this nature there is always one direction in which they behave in all respects like ordinary transparent bodies. This is called the optic axis, and it is evidently in the direction of the axis of revolution of the ellipsoid of the wave front. (It is not a *line*, but a direction; and so all lines drawn in this direction within the body are optic axes.) These bodies are therefore called uniaxial. Let such a body have a face cut and polished making an angle θ with the optic axis, and let the paper make a section perpendicular to this face and including the optic axis. If

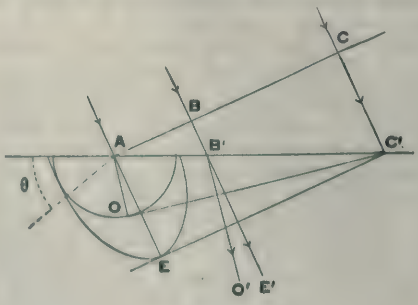

Fig. 17.

a plane wave front *ABC* is incident on this face, the disturbance at *A* in the uniaxial body sends out its double wave front, the section of which —a circle and an ellipse—is shown; and while the disturbance goes from *C* to *C′* in the air let the double wave front advance as shown. Then at this instant the wave fronts in the uniaxial body may be easily seen to be planes which pass through the line perpendicular to the paper at *C′* and are tangent to the sphere and to the ellipsoid. The disturbance from *A* has thus reached the points of tangency *O* and *E*; *AO* and *AE* are called the ordinary and the extraordinary *rays;* and it is evident from geometry that the latter ray does not in general obey either of the laws of ordinary refraction. Two lines drawn perpendicular to the wave fronts, e.g., *B′O′* and *B′E′*, are called the wave normals; and it is seen that in general the extraordinary ray does not have the same direction as the extraordinary wave normal, i.e., the ray is advancing in a direction different from the direction of advance of the wave front. In other doubly refracting bodies there are two optic axes; such are called biaxial. Fresnel explains their optical properties by assuming a peculiar kind of wave surface, which is too complicated for description here.

The wave surface of Huygens for uniaxial bodies may be regarded as definitely established by experiment; while all that can be said in regard to Fresnel's wave surface for biaxial bodies is that it is most probably correct.

Interference and Diffraction. The optical phenomena whose discovery established the fact that light is due to wave motion are those of interference (q.v.) so called. The simplest illustration of these is due to Thomas Young and is called after him. Three opaque screens are arranged in order; in the first there is a narrow slit at *O*, illuminated with some homogeneous light, e.g., a flame burning sodium; in the second there are two slits, O_1 and O_2, close together, parallel to the first and at equal distances from it; the waves spreading out from *O* illuminate the slits O_1 and O_2 so that they in turn become sources of *two identical* trains of waves—if the source at *O* flickers or changes in any way, both the secondary sources change together; waves from these two sources illuminate the third screen. Bands parallel to the slits, alternately dark and colored, are observed on this screen. These may be explained immediately if light is due to wave motion; because at points on the screen such that their distances to O_1 and O_2 differ by half a wave length or by an odd number of half wave lengths there will be complete interference, and consequently darkness. Similarly at points on the screen whose distances from the slits O_1 and O_2 differ by a whole number of wave lengths the two trains of waves will reënforce each other and there will be light. (It is evident that there is no destruction of energy—only a redistribution of it.)

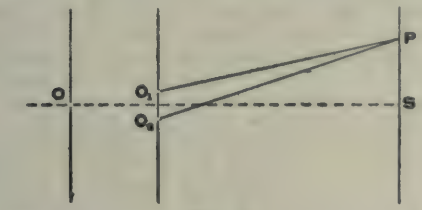

Fig. 18.

Referring to the figure, if *P* is a point in a bright band, $O_2P - O_1P = N\lambda$, where *N* is any integer number, 0, 1, 2, 3, etc., and λ is the wave length of the waves. If the distance from the receiving screen to the one with the two slits is *a;* if the distance apart of the two slits is *b*—a small quantity compared with *a;* and if *PS* is *x*, also a small quantity, it is seen by geometry that

$$\frac{x}{a} = \frac{O_2P - O_1P}{b}.$$

Hence $N\lambda = \frac{bx}{a}$; and the distance apart of the bright bands is therefore $\frac{a\lambda}{b}$. This distance, and both *a* and *b*, can be measured; so this experiment gives a means of determining λ. It is found that as the colors change from red to yellow, to green, to blue, the wave length of the corresponding waves becomes less. If white light is used, the central band at *S* is white, but the others are colored, all merging into each other. The wave length of the yellow light from a sodium flame is found to be 0.00005893 centimeters. Since the velocity of the waves is 3×10^{10} centimeters per second, the wave number for these yellow waves is about 5×10^{14}. (For other wave lengths, see Spectroscopy.) It is thus possible now to compare the indices of refraction of a given material—e.g., water—with the corresponding wave lengths. A curve plotted with the indices of refraction as ordinates and the wave lengths as abscissæ is called the dispersion curve of the substance. There are many other ways of securing two identical slits as sources of light besides the one here described, e.g., Fresnel's biprism and double mirror; but for a full description reference should be made to some treatise on light.

One of the most interesting phenomena depending for their explanation upon interference is that of the color of thin plates and of Newton's rings, as shown in the colors of soap films, very thin films of glass, or when a convex glass lens is pressed closely against a piece of plane glass. When parallel rays of light are incident upon a transparent film of uniform thickness, that portion which comes back, at the proper angle of reflection, is a mixture of waves which have suffered reflection at the top surface of the film and those which, having entered the film, have been reflected at the lower surface and then have emerged directly at the top surface or emerged after a series of internal reflections. If the relative retardation of the component trains of homogeneous waves is such that they have different phases equivalent to a difference of an odd number of half wave lengths, there will be complete interference; and it can be shown that all the waves have been transmitted through the film, so there is no loss of energy. If, therefore, the incident light is white, those waves will be absent from the reflected beam which satisfy the above condition; and so it will appear colored. It is proved easily that if the thickness of the film is *e*, its index of refraction with reference to air *μ*, and the angle of incidence of the light on the lower surface of the film *a*, there will be complete interference in the reflected light for a train of waves whose wave length in the film is λ if

$$N\lambda = 2e\mu\cos a,$$

where *N* is any whole number.

It is evident that the transmitted light is in any case complementary to that reflected; but there will always be differences in the apparent brightness of the colors, because there is so much white light transmitted.

If the film is of varying thickness, there will be different colors corresponding to the values of λ which satisfy the above equation for different values of e, the thickness. If homogeneous light—all of one color—is used, there will be seen colored bands separated by dark ones, depending upon the fact that the above equation is satisfied by different values of N (0, 1, 2, 3, etc.) for the same value of λ, if e is varying. The colored effects seen with white light depend upon the superposition of these colored bands due to the components of white light. It should be noted, however, that in order to see these colored bands the eye must be focused on the *surface of the film*, and a comparatively large source of light must be used. This is the explanation of Newton's rings.

If the film has perfectly parallel plane faces and is illuminated by a large source of homogeneous light (e.g., a flame), colored *rings*, separated by dark ones, may be seen by looking through the film at the source, the eye being focused for *an infinite distance.* These same rings may be seen to better advantage if a telescope focused for infinity is used to view the light. It is in this manner that the interferometers of Michelson and of Fābry and Perot are used. The colors obtained in Lippmann's method of color photography (q.v.) depend upon this principle of thin plates. The colors of the opal are due to similar causes. If a soap bubble could be imagined crushed and crumpled up, the colors would be like those of the opal.

There are two cases of diffraction which deserve special attention: one is when light with a plane wave front falls upon a single rectangular or circular opening, and the other is when waves with a plane wave front fall upon a series of rectangular openings regularly or irregularly spaced.

1. *Diffraction through a Rectangular Opening.*—If homogeneous waves with a plane wave front fall upon such an opening of width b and are then brought to a focus on a screen by a converging lens, it is observed that the illumination on the screen consists of a narrow band of light fading away into two dark lines, on the farther sides of which come two faint bright lines, etc., the central bright line being much more intense than the successive lines. This is called a diffraction pattern. If f is the focal length of the lens, the distance from the centre of the central light band to the centre of the neighboring dark band is $f\frac{\lambda}{b}$. This is illustrated by light from a distant star passing through a rectangular opening. If light from another star apparently near the first passes through the same opening, its diffraction pattern will be the same as for the former, but shifted slightly sidewise. If the angle between lines drawn from the slit to the two stars is a, the pattern will be shifted sidewise a distance equal to $f\tan a$. If this amount of shift brings the maximum bright band of one pattern to coincide with the minimum of the other, the resultant diffraction pattern will be such that it is *just possible* to distinguish the presence of two patterns. If the pattern is shifted less, it is impossible to recognize the presence of the two. The limiting closeness of the stars, so far as their angular separation is concerned, is then when

$$f\tan a = \frac{f\lambda}{b},$$

or, since a is very small, when

$$a = \frac{\lambda}{b}.$$

This is called the resolving power for a rectangular opening of width b.

Similarly, when a circular opening is used, the diffraction pattern consists of a bright spot fading rapidly into a dark ring, then a faint ring, a dark ring, etc.; and if the diameter of the opening is d its resolving power may be shown to be

$$a = 1.22\frac{\lambda}{d}.$$

Similarly, if two point sources are at a distance x apart and are at such a distance from a lens that the angular aperture of the lens as seen from either point is θ, the lens cannot resolve the points if x is so small that

$$x\sin\frac{\theta}{2} = \frac{\lambda}{2}.$$

This determines the resolving power of a microscope. The greatest value θ can have is 180°, and under these conditions $x = \frac{\lambda}{2}$.

(If the two points are in a medium whose index of refraction with reference to air is n—e.g., oil immersion microscopes—this limiting distance is $x = \frac{\lambda}{2n}$.)

2. *Diffraction through a Series of Parallel Rectangular Openings Regularly Spaced*, i.e., a grating. (See DIFFRACTION AND DIFFRACTION GRATINGS.)—If the width of each opening is b and of each opaque strip separating the openings is a, the sum $(a + b)$ or e is called the grating space. In general these gratings are made by ruling lines by means of a diamond point on a glass plate. Where the diamond makes scratches the surface is rendered opaque, and the spaces in between are transparent slits. An equally good arrangement is to rule lines on a polished metallic mirror and use it as a reflecting grating. As a rule the grating space is made very small, there being as many as 15,000 or 20,000 lines to the inch. (See DIVIDING ENGINE.) If homogeneous waves with a plane wave front are incident upon a grating at such an angle that the perpendicular to the wave front makes an angle i with the perpendicular to the grating, the waves diffracted through the openings will be broken up into beams leaving the grating in such direction as to make with the perpendicular to the grating angles given by the value of θ in the formula

$$N\lambda = e(\sin i + \sin\theta),$$

where N is any whole number, 0, 1, 2, 3, etc., positive or negative. The simplest case is when the incident light is perpendicular to the grating, i.e., $i = 0$; hence

$$\frac{N\lambda}{e} = \sin\theta.$$

The best method of observing these diffracted beams is to focus them upon a screen by means of a lens. The diffraction pattern will be a series of bright bands corresponding to the above formula, with other faint maxima and minima unless the grating space is small. If this is the case, the subsidiary maxima disappear and the bright bands shrink up into fine lines, the smaller the grating space the narrower these lines of light. Thus there will be lines of light for $\theta = 0$, $\theta = \sin^{-1}\frac{\lambda}{e}$, $\theta = \sin^{-1}\frac{2\lambda}{e}$, etc.; i.e., there will be a central line and others on each side of this, forming what are called the first, second, etc., spectrum according as $N = 1, 2$, etc. The grating space can be measured; the order of the spectrum is known in any particular case; θ can be measured by a goniometer, and so the wave length of the ether waves may be determined. This is one of the most accurate methods known for the measurement of the wave lengths of ether waves.

If white light is used, each component train of waves will have its own maxima at definite angles; and so the light is analyzed into its parts, forming a central white image and series of colored spectra on each side. It may be shown that if m is the entire number of grating spaces and if two trains of waves of wave length λ and $\lambda + \Delta\lambda$ (where $\Delta\lambda$ is small) are viewed in their spectra of the Nth order, they will have bright lines so narrow as to be separate enough to recognize the existence of both if $\Delta\lambda = \frac{\lambda}{mN}$. $\frac{\lambda}{\Delta\lambda} = mN$ is defined to be the resolving power of the grating. A spectrum in which each train of waves of a definite wave length is represented by a line of light as fine as possible is called a pure spectrum.

When diffraction through a great number of equal parallel slits irregularly spaced takes place, it may be shown that the effect is simply that of a single slit, only greatly intensified. Similarly, if a great number of circular openings of the same size or of circular disks of the same size are placed at random in front of a point source of light, the diffraction pattern is simply that due either to a single opening or to a single disk. The color halos around the moon are in certain cases due to the diffraction past circular disks of floating drops of water.

Polarization. All the phenomena so far discussed depend for their explanation upon the assumption that light is due to wave motion; and therefore similar ones may be observed with all kinds of wave motion; e.g., aërial waves may be reflected, refracted, and diffracted, and may be made to interfere. But there are certain other phenomena in the case of light which establish the fact that the ether waves which produce light are *transverse*, i.e., the vibration in the ether is at right angles to the direction of advance of the waves. In other words, the vibration in the ether is in the wave front as the waves advance in the pure ether or through isotropic material bodies. This may be proved in several ways. Perhaps the simplest is this: cut two identical plates of a crystal of tourmaline; let ordinary white light from the sun or from a lamp pass through one of these plates and then let it fall perpendicularly upon the other; if this second plate is turned slowly around an axis parallel to the rays of light, it will be noticed that, during one complete revolution of the plate through 360°, there are two positions differing by 180° for which no light emerges from the second plate, while halfway between these two positions the emerging light has its maximum intensity. This observation can be accounted for only if it is assumed that, after the waves have emerged from the first plate, the vibrations in the ether are all in parallel straight lines perpendicular to the direction of the rays, the direction of the vibration being in some way connected with the properties of the crystal of tourmaline; this means that the crystal transmits vibrations of a definite direction only, which is fixed by its crystalline properties.

Similarly, the second crystal will transmit only those vibrations which are in straight lines parallel to some line fixed by its crystalline properties. If, therefore, the waves incident upon the second plate have their vibrations parallel to this fixed direction—and this will happen twice in one complete revolution of this plate around an axis parallel to the rays—the waves will be entirely transmitted; whereas, if the direction of the vibration in the incident waves is at right angles to the fixed direction in the second plate, no light can be transmitted; and for positions where these two important lines make an acute angle with each other, a component of the energy of the waves passes through. The waves after passing the first plate of tourmaline are said to be plane polarized, meaning that all the vibrations in the waves are now in parallel straight lines. A test for plane polarized waves, further, is to see if they can pass through a thin plate of tourmaline with maximum intensity for two positions of the plate, and be cut off completely for two positions at right angles to the other two.

In this way it may be shown that each of the beams of light transmitted by a doubly refracting substance is plane polarized, but that the position of the tourmaline plate required to produce extinction of one beam is perpendicular to that required to extinguish the other: the two beams are said to be polarized in planes at right angles to each other. (In fact tourmaline is itself a uniaxial double refracting substance; but unless it is made in a very thin plate, only one kind of ray is transmitted, the extraordinary—the ordinary rays are absorbed in the crystal.) Similarly, if ordinary light falls upon a plane face of any isotropic transparent substance, e.g., glass or water, both the reflected and the transmitted waves are found to contain some that are plane polarized, but in planes that are at right angles to each other for the two cases; and for a definite angle of incidence for each such substance all the reflected light will be plane polarized. (Different kinds of plane polarized light are distinguished by saying that they are polarized in different planes. By definition the plane of polarization of light polarized by reflection is taken as the plane which includes the incident and reflected rays.)

This angle of incidence is called the polarizing angle for the transparent substance. (The tangent of the polarizing angle equals the index of refraction. This is known as *Brewster's law.*) The refracted light in this case is a mixture of ordinary light and plane polarized light.

The two methods most in use for producing plane polarized light are to allow ordinary light to be reflected from glass at the polarizing angle, and to allow ordinary light to pass through a Nicol prism. This consists of two pieces of a crystal of Iceland spar cut in a definite manner and cemented together by Canada balsam; Iceland spar is a uniaxial crystal and so the incident light is broken up into two trains of waves, the ordinary and the extraordinary; when these reach the layer of Canada balsam, the former suffers total reflection, while the latter is transmitted; thus the emerging light is plane polarized. It is found, too, that the light scattered by fine particles, e.g., the blue light of the sky, is plane polarized.

It is possible by several methods so to alter plane polarized light that all the vibrations in the ether as the waves pass are in circles or in ellipses; such light is called circularly or elliptically polarized. Ordinary light such as comes from the sun or a lamp can be considered as a mixture of all kinds of polarized light, plane, circular, and elliptical. (If plane polarized light is reflected from a metallic surface it becomes elliptically polarized.)

If ordinary light is incident upon a thin plate of any doubly refracting substance, it may be shown that two beams of plane polarized light—with their vibrations at right angles to each other—will be transmitted; and further, these beams will travel through the plate at different speeds, so that on emerging one will be slightly in advance of the other so far as the phase of the waves is concerned. If these two beams now enter a Nicol prism, only a component of each will be transmitted, for the prism allows to pass vibrations in a definite direction only, which direction is not in general that of the vibration in either of the two beams. If the light which falls upon the thin plate is itself plane polarized, it will be broken up as before into two beams, and they will be recombined into a plane polarized beam by the Nicol prism. The two component beams are in different phases; and, if one is retarded by an amount equal to half a wave length for any color or any odd number of half wave lengths, then, when these beams are combined by the Nicol so as to have their vibrations all in one direction, the waves of this particular color will be absent, owing to interference, if the intensities of the two coinciding beams are the same; and if the incident light is white the emerging light will be colored. (If the incident light had not been plane polarized, there would not have been a definite relation between the intensities of the beams coinciding in the Nicol prism.) This experiment offers a most delicate test of the double refraction of any substance: place two Nicol prisms in line, and turn one around its axis until no light is transmitted through the two—they are said to be crossed; now introduce between them the substance to be investigated. If it is doubly refracting, light will now be transmitted through the Nicol prisms. This is sometimes called depolarization.

ETHER AND MATTER

Among the phenomena of light which can be explained only by assuming some definite connection between the ether and matter, are dispersion, both regular and anomalous; absorption and emission; color; fluorescence and phosphorescence; rotation of the plane of polarization by quartz and other bodies; metallic reflection; the various magnetic actions on light; etc.

Dispersion. As has been already explained, dispersion is due to the fact that ether waves of different wave length have different indices of refraction for any one material substance; i.e., they have different velocities in it. As a rule the velocity decreases, i.e., the index of refraction increases, as the wave length decreases. This is called regular dispersion. There are, however, many substances for which this is not true; e.g., in fuchsin the indices of refraction of the red and yellow waves are greater than those for the blue and violet. If a spectrum of white light is formed on a screen by means of a slit, a prism of glass, and a lens, the colors will be arranged in the order red, yellow, green, blue, violet—the red being deviated least, i.e., having the least index of refraction. If, however, a prism of fuchsin is used in place of the glass one, the order of colors will be blue, violet, red, yellow—the green being absent. Fuchsin is a substance having a green surface color (see COLOR), and so this color is absent in the transmitted light. The resulting spectrum produced by a fuchsin prism is then exactly as if the ordinary spectrum had been cut in two by the removal of the green and the two halves displaced over each other. In other words, with bodies possessing surface color of a definite wave length, the indices of refraction of the waves on the two sides of the absorbed waves are changed; if their indices are less than that of the absorbed color for ordinary media, they are increased, and vice versa. This is known as anomalous dispersion.

Dispersion, both regular and anomalous, is due to the reaction of the electrons in the material atoms upon the ether-waves. As these enter the matter they produce vibrations of the electrons, and the effect is to change the apparent inertia of the ether, thus causing a change in the velocity of the waves.

Absorption. When white light falls upon any material substance there is always a certain amount scattered from the surface, and also as a rule some scattered from the interior portions of the body if light enters. The light scattered from the surface is white, but if the body is a piece of polished metal or has a metallic lustre, there is mixed with the white light some that is colored. This colored light is due to the fact that there is a certain amount of absorption of waves of a particular wave length at the *surface*. Thus, gold appears yellow because out of the incident white light the bluish-green light enters at the surface, and the yellow light is reflected. If a sheet of gold is hammered out extremely thin, the transmitted light is bluish. If the light penetrates into a substance, and is either transmitted through or reflected out by small solid particles as mirrors, the color is generally the same, being due to the absorption of certain waves in the body of the substance. (The energy of these absorbed waves goes generally into heat effects, but may be spent in producing fluorescence, q.v.) Some substances absorb two or more colors to different extents; so a thin plate of it will be of a different color from a thick one.

As explained in the article on COLOR, the particular color ordinarily attributed to a substance is that perceived by a normal eye when viewing the substance in white light. There are two methods for determining the cause of the color of an object. One method is to put it, if it is not opaque, between the slit and prism of a spectroscope, the slit being illuminated by white light, and to notice the change in the spectrum. The resulting spectrum is called the absorption spectrum of the body, and the colors which are transmitted are the ones which, when combined in the eye, produce the color of the object. The other method is to throw a pure spectrum of white light on a screen, and to move the object slowly through the spectrum; if it appears black when held in any color, it shows that the waves of this color are absorbed by the object. If two pieces of colored glass are superimposed, or if two colored paints are mixed, the resulting color is that due to the waves which are left after each glass or each paint has absorbed its colors; it is therefore a process of double subtraction of colors.

Absorption must be due to the fact that the electrons in the atoms of the matter can vibrate in definite periods; and if ether waves of a proper period enter the substance they will by resonance set these in vibration and so lose their own energy. If the energy thus gained by the electrons is dissipated among the molecules, increasing their energy, heat effects are produced. It may happen, however, that electrons are set vibrating by the absorption of ether waves, and, instead of having their energy spent in heat effects, other ether waves are emitted. This is called fluorescence (q.v.). Thus, a solution of quinine absorbs ether waves whose period is so short that they are invisible, and in return for them emits violet and blue light. If the fluorescent body continues to emit light for some time after the incident light is cut off, it is said to be phosphorescent. In the case of solids and liquids the fluorescent light is of a longer wave length than the absorbed light; but with vapors the phenomenon is much more complicated.

Radiation. As explained in the article RADIATION, all material bodies are emitting ether waves; i.e., by reason of the vibrations of the electrons in the atoms, disturbances are produced in the ether. The nature of these waves emitted by any body may be determined by analyzing the radiation, using a suitable dispersing apparatus—prism or grating or interferometer—and studying the resulting spectra. The difficulty comes in obtaining instruments which detect the presence of ether waves of all lengths. These waves carry energy; and if an instrument absorbs them, some change in it will be produced, provided it is sensitive enough, the kind of change depending on the nature of the instrument and the wave length of the waves. Thus, if waves of wave length extending from about 0.000015 centimeter to 0.00007 centimeter fall upon suitable photographic plates, there is chemical action produced; if waves of wave length between about 0.000039 centimeter and 0.000075 centimeter enter the human eye, color is perceived; if waves of wave lengths from 0.00004 centimeter to 0.007 centimeter are absorbed by suitable thermometers (q.v.), change in temperature is noticed. Waves longer than 0.015 centimeter have not yet been observed as being emitted by ordinary matter; waves longer than 0.2 centimeter may, however, be produced by electrical means. Using proper instruments, it has been proved that all solids and liquids, with only two or three exceptions, emit continuous spectra; i.e., waves of all wave lengths between certain limits can be shown to be present. Gases, however, when rendered luminous by the passage of an electric discharge through them or when produced by vaporizing solids in the electric arc, give discontinuous spectra; i.e., only isolated trains of waves are present. This is what would be expected.

Since the emission spectrum of a gas is due to the natural frequencies of the electrons in the atoms, and since the absorption spectrum of any body when light of a continuous spectrum falls upon it is due to the absorption of the energy of those incident waves whose frequencies are the same as those of the electrons, it might be expected that those waves present in the former are absent in the latter. This is observed to be true, with certain limitations. See RADIATION and SPECTROSCOPY.

Rotation of the Plane of Polarization by Quartz, etc. A most important connection between matter and the ether is shown by the fact that when plane polarized light is passed through certain bodies—called optically active substances—the emerging light is plane polarized, but the plane of polarization, i.e., the direction of the vibration, has been rotated. If a Nicol prism is so placed as to extinguish the plane polarized homogeneous light before the optically active substance is introduced in the path of the light, it will be necessary to turn the Nicol around its axis through a certain angle in order again to extinguish the light after the substance is introduced between the source of light and the Nicol. In some cases the Nicol must be given a right-handed rotation, and in other cases a left-handed one. If the direction of the light is reversed in the body, so is the rotation. Bodies which necessitate the former are called dextrorotatory, and those which require the latter, lævorotatory. The amount of rotation of the plane of polarization is different for different substances; it is different for waves of different color, being greater for shorter waves; it varies directly as the thickness of the layer of the substance. In some specimens of quartz the rotation is right-handed; in others, left; and it is found that these two kinds of quartz have a similar difference in their crystalline structure. Turpentine is optically active; so are solutions of certain sugars, two forms of tartaric acid, and all organic compounds involving an asymmetrical carbon atom.

The explanation of this rotation was given by Fresnel and was verified experimentally by Brace. The rectilinear vibrations of the incident plane polarized light are resolved by the optically active substance into two beams of circularly polarized light; one right-handed, the other left-handed. These two beams traverse the substance with different velocities; so, when they emerge and again combine to form a rectilinear vibration, its direction is not the same as that in the incident beam.

Electromagnetic Phenomena. The connection between light and electromagnetic phenomena is shown in several ways: the identity in the properties of light waves and the waves produced by electric oscillations; the rotation of the plane of polarization in a magnetic field; the Kerr phenomenon; the Zeeman effect; etc.

It is shown in the article on ELECTRICITY that the waves produced by electric oscillations are transverse waves in the ether, and that they have the same velocity as light waves. They can be polarized, can be made to interfere, can be reflected, refracted, etc. The shortest wave length so far observed, for waves produced by electrical oscillations, is about 2 millimeters. It can be shown also that the velocity of ether waves in any transparent medium should vary as the square root of the reciprocal of the product of the electric and magnetic inductivities of that medium. The values of these quantities

(K and μ) for the pure ether can be written K_0 and μ_0; therefore the index of refraction of the transparent medium is $n = \sqrt{\frac{K\mu}{K_0\mu_0}}$. For all such media $\mu = \mu_0$; and $K_0 = 1$ on the C. G. S. electrostatic system; so $n = \sqrt{K}$, where K is the value of the electric inductivity (or dielectric constant) of the transparent medium. This n is the index of refraction for *very long waves*, because K is always measured by methods which involve slow oscillations. This formula is verified by experiment in many cases.

As noted also in the article on Electricity, when a beam of plane polarized light is made to pass along the axis of a powerful electromagnet, the plane of polarization is rotated in the direction in which the current in the magnetizing helix is flowing. This is called the Faraday effect. So, if the direction of the beam of light is reversed, the rotation is not. The amount of the rotation varies greatly with the transparent matter which occupies the magnetic field; it is proportional to the strength of the magnetic field; it varies with the wave length and with the temperature. This rotation is due to the motions of the electrons in the atoms caused by the action of the magnetic field. A moving electron is equivalent to an electric current; and its path is therefore changed if there is a magnetic field. For a full explanation some comprehensive treatise on light should be consulted.

It was stated in speaking of polarized light that if plane polarized light is incident upon a plate of polished metal, the reflected light is elliptically polarized. Kerr discovered that, if the metal surface is one end of a magnetized bar of iron, the reflected light is not the same as from a surface of unmagnetized iron. He found further that the changes were opposite in kind if the reflection took place from first a north pole and then a south one. Changes are also observed when the light is transmitted through thin films of magnetized iron.

Zeeman Effect. A most important discovery, made by Zeeman, has led to a series of interesting observations. He has shown that the light emitted by a flame when placed in a magnetic field is different from that emitted ordinarily, and further that there are differences depending upon whether the flame is viewed along the field of magnetic force or at right angles to it. These observations prove that the ether waves emitted by the flame are actually produced by the vibrations of minute portions of matter electrically charged, which have been called electrons. (In this connection reference should be made to the *Reports of the International Congress of Physics*, Paris, 1900, vol. iii, and to P. Zeeman, *Researches in Magneto-Optics*, London, 1913.)

Bibliography. Thomas Preston, *Theory of Light* (London, 1901), is to be recommended as an accurate and interesting treatise on optical theory. Other works to be recommended are: Henry Crew, *Wave Theory of Light* (New York, 1900); Paul Drude, *Lehrbuch der Optik* (2d ed., Leipzig, 1906; Eng. trans. by Mann and Millikan, New York, 1907); R. W. Wood, *Physical Optics* (ib., 1911). In the chapters on Optics in A. Winkelmann, *Handbuch der Physik*, vol. ii (2d ed., Leipzig, 1903), and in Müller-Pouillet, *Lehrbuch der Physik*, vol. ii (10th ed., Brunswick, 1906), will be found complete descriptions and explanations of optical phenomena.

LIGHT, Aberration of. See Aberration of Light.

LIGHT, Easement of. The right to the free access of light to one's windows from and over the land of another. The right to light arises only by grant or by use and enjoyment for a period of time long enough to confer what is known as a prescriptive right, i.e., from time immemorial. When acquired in the latter way, it is in England known as the easement of ancient lights (q.v.). In the United States it can in general be acquired only by grant, it being regarded as incompatible with prevailing conditions to permit its acquisition as against a neighbor by mere lapse of time. It has, however, been established by the New York Elevated Railroad cases (Story *v.* New York El. R. R. Co., 90 N. Y. Rep. 122) that a householder has an indefeasible right to light and air with respect to windows opening on a public street. The easement of light belongs to the class of so-called negative easements, as it involves no trespass or encroachment on a neighbor's land, as does the easement of a way, of drainage, and the like, but has the purely negative operation of preventing him from so using his land as to interfere materially with the light enjoyed by the premises to which the right attaches. The easement once created continues so long as the house stands to which it is appurtenant or until the latter is so altered as to show an abandonment of the right by the owner thereof. It should be noticed that one may always open windows overlooking another's premises without thereby infringing the latter's property rights, but that, in the absence of an easement of light, such windows may be darkened by the owner of such premises at his pleasure. See Easement; Prescription.

LIGHT, Equation of. See Equation of Light.

LIGHT, Standards of. See Photometry.

LIGHT BRAHMA. See Fowl.

LIGHT'ER (from *light*, AS. *lēoht*, Goth. *leihts*, OHG. *lihti*, *līht*, Ger. *leicht*, light, not heavy; probably connected with Lat. *levis*, Lith. *lengwùs*, Gk. *ἐλαχύς*, *elachys*, Skt. *laghu*, *raghu*, light). A strong, heavy, flat-bottomed boat of large size used for transporting cargo or heavy weights to and from ships. It is usually open, but the larger lighters have a deck and very large hatches with light, removable covers. In large harbors some lighters have a mast and a single sail set on a gaff, but without a boom. In small harbors oars or sweeps are used. The present very general use of tugs in the important harbors of the world has caused the development of large lighters that are designed to be towed and have no means of self-propulsion. Large steam and motor propelled lighters are becoming common. The speed of these is usually low—5 to 10 knots—the machinery placed well aft, and the decks and holds for cargo are forward of the machinery and deck houses. A lighter of this type usually has a mast and derricks with a power hoist for handling cargo.

LIGHT'FOOT, John (1602–75). One of the earlier Hebrew scholars of England. He was born at Stoke-upon-Trent in Staffordshire, March 29, 1602. He studied at Christ's College, Cambridge, and, after entering into orders, became chaplain to Sir Rowland Cotton in London, who, being himself a good Hebrew scholar, inspired Lightfoot with a desire to become one also. In 1629 appeared his *Erubhim, or Miscel-*

lanies, Christian and Judaical, dedicated to Cotton, who in 1630 presented him to the rectory of Ashley in Staffordshire. In 1642 he removed to London that he might have better opportunities for the prosecution of his favorite study; and in 1643 he was chosen rector of St. Bartholomew's, near the Exchange, to the parishioners of which he dedicated his *Handful of Gleanings out of the Book of Exodus* (1643). His most important work is *Horæ Hebraicæ et Talmudicæ, etc.* (1658–74), edited in Latin by Carpzov (Leipzig, 1675–79) and in English by Gandell (4 vols., Oxford, 1859). It is a commentary on parts of the New Testament from rabbinical sources. Lightfoot was one of the assembly of divines who met at Westminster in 1643 and, in the debates that took place there, betrayed predilection for the Presbyterian form of Church government. In 1644 he became rector of Great Munden, Hertfordshire, and so remained the rest of his life. In 1650 he was appointed master of St. Catharine Hall, Cambridge, and in 1654 vice chancellor of the university. At the Restoration he was confirmed in his rectory and mastership, and in 1662 he complied with the terms act of the university. He was made a prebendary of Ely in 1668 and died there, Dec. 6, 1675. His works in English, original or translated, first appeared in a collected edition (2 vols., London, 1684); the best edition is by J. R. Pitman, with biography and bibliography (13 vols., ib., 1822–25). Consult D. M. Welton, *John Lightfoot the Hebraist* (Leipzig, 1878), and Thomas Hamilton, in the *Dictionary of National Biography*, vol. xxxiii (London, 1893).

LIGHTFOOT, Joseph Barber (1828–89). An English prelate and student of early Christian literature. He was born in Liverpool and educated at King Edward's School, Birmingham, where his most intimate friend was E. W. Benson, the future Archbishop. Thence he went to Cambridge, where he was elected a scholar of Trinity in 1849 and a fellow in 1851. He was ordained deacon in 1854 and priest in 1858. He spent 30 years at Cambridge, taking a prominent place in all educational matters; he succeeded Ellicott in 1861 as Hulsean professor of divinity, and Selwyn in 1870 as Lady Margaret professor. The duties of a canonry at St. Paul's Cathedral (from 1871) and of a hard-working member of the company of New Testament revisers (1870–80) filled up all the time he could spare from Cambridge work. He had declined the bishopric of Lichfield in 1867, but accepted that of Durham in 1879. One of his first steps was to move for a division of the immense diocese by the creation of the see of Newcastle; and he labored indefatigably until his death in 1889 to promote every form of spiritual activity. He left a number of important theological works, especially the great edition of the Apostolic Fathers (*Clement of Rome*, 1869, 2d ed., 1890, on which he was working only three days before his death; *Ignatius and Polycarp*, 1885, 2d ed., 1889), and commentaries with revised text on the *Epistles to the Galatians* (1865), *Philippians* (1868), *Colossians and Philemon* (1875), all of which have gone through numerous editions.

LIGHT'HALL, William Douw (1857–). A Canadian author. He was born in Hamilton, Ontario, and graduated at McGill University in 1879. He subsequently studied law, was admitted to the bar in 1881, and became prominent in his profession in Montreal. He devoted much of his time to literature, was made an honorary member of the Scottish Society of Literature and Art, a fellow of the Royal Society of Literature of Great Britain, vice president of the Canadian Society of Authors, and founded the Society of Canadian Literature. He was interested in municipal reform and was one of the founders of the Union of Canadian Municipalities. His publications include: *Thoughts, Moods, and Ideals* (1887); *The Young Seigneur* (1888); *Songs of the Great Dominion* (1889); *The False Repentigny* (1889); *An Account of the Battle of Châteauguay* (1889); *Montreal after 250 Years* (1892); *The False Chevalier* (1898); *Hiawatha the Great* (1901); *Canada a Modern Nation* (1904); *The Master of Life* (1908); *The Governance of Empire* (1910).

LIGHTHORSE HARRY. A name given to the American general Henry Lee, on account of his cavalry operations during the Revolutionary War.

LIGHTHOUSE. A building on some conspicuous point of the seashore, an island or rock, from which light is exhibited at night as a guide to mariners. The importance of such structures has been understood since very remote times, and the ancients devoted considerable attention to lighthouse construction; but it is only within the last 100 years that these aids to the mariner have been developed upon systematic and scientific lines. At present all maritime nations have governmental bureaus or departments whose sole duty it is to establish and maintain lighthouses. In France this body is known as the Commission des Phares, and its membership comprises four engineers, two naval officers, one member of the Institute, one inspector general, and one hydrographic engineer. In England the Corporation of Trinity House has charge of the English lights; the Scottish lights are under the management of the Commissioners of Northern Lights, and the Irish lights are under the care of the Corporation for Preserving and Improving the Port of Dublin, which is commonly called the Ballist Board. The fund with which these boards carry on their work is provided by the one halfpenny per ton due charged every vessel at each time it passes the lighthouse. In the United States the construction and maintenance of lighthouses is in charge of the Commissioner of Lighthouses.

Ancient Lighthouses. The oldest lighthouses known were the towers built by the Lybians and by the Cushites of Lower Egypt. The light consisted of burning fuel in a brazier hung from a pole projecting from the tower towards the sea. The Romans built many fine light towers in Italy, but comparatively little is known about their construction and dimensions. Perhaps the most famous tower of antiquity was that erected on the island of Pharos near Alexandria about 285 B.C. The Romans built light towers at Dover and Boulogne on the English Channel. Little is known of the Dover tower, but the Boulogne tower was a masonry structure octagonal in plan, 192 feet in circumference and 200 feet high. It was built in 12 stories, each three feet less in diameter than the one beneath it. The rock on which this lighthouse was situated was undermined by the waves and fell, with the lighthouse, between 1640 and 1645, after the light had guided mariners for probably 1450 years. Towers of later mediæval times which are deserving of mention are the Torre del Capo, near Genoa, first built in 1139, removed in 1512 and rebuilt in 1643; the Pharos of Metoria, built by the Pisans in 1154 and several times destroyed and rebuilt; and the Tower of Cordouan, situated at the mouth of the Gironde and finished in 1610. These are only a few examples of ancient lighthouses, but they indicate quite well the general character of these early works, viz., towers of masonry on the tops of which were built fires to serve as lights.

Modern Lighthouses. Modern lighthouses may reasonably be said to date from the construction of the Eddystone Lighthouse by John Smeaton in 1756–59. The Eddystone rocks are a particularly dangerous reef lying in the English Channel about 14 miles from Plymouth, England. Smeaton's Eddystone Lighthouse was a circular masonry tower, broad at the base and narrowing by a curve to a slender waist at the base of the lantern housing. The masonry of the tower was a very intricate piece of dimension stone masonry, the stones being dovetailed together in such a way as to make each course practically a single stone. The height of the masonry structure to the focal plane of the lantern was 72 feet. In 1877 work was begun on a new Eddystone lighthouse to replace Smeaton's, which was not high enough to keep the waves from dashing over the lantern, and which, moreover, had become endangered by the undermining of the natural rock. In the new structure the tower was made cylindrical to a height of 2½ feet above the highest tides and diminishing in size above this level. It was made 132 feet high from high-water level to the focal plane of the lantern, the masonry being of dimension stones cut so as to interlock and further held together by bronze bolts. The new lighthouse was completed in 1882.

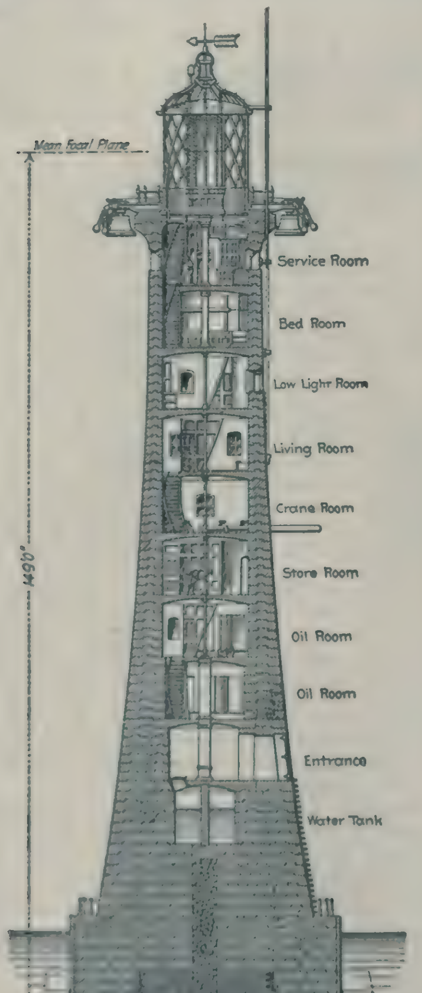

FIG. 1. VERTICAL SECTION SHOWING INTERIOR OF NEW EDDYSTONE LIGHTHOUSE.

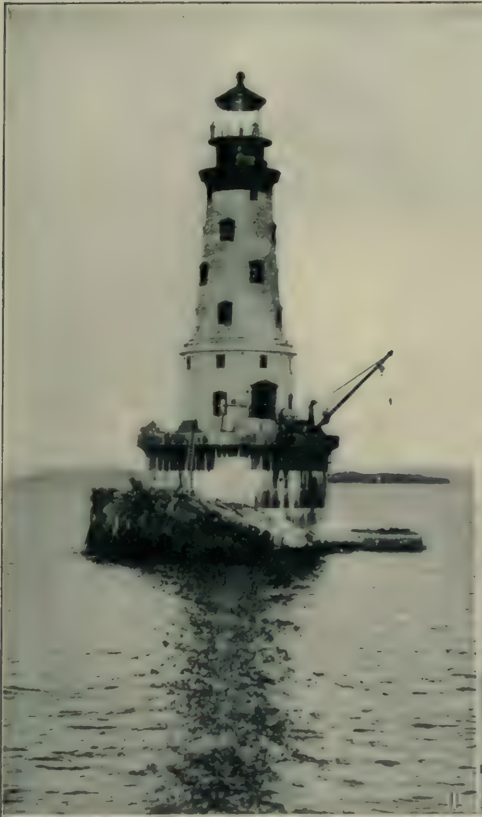
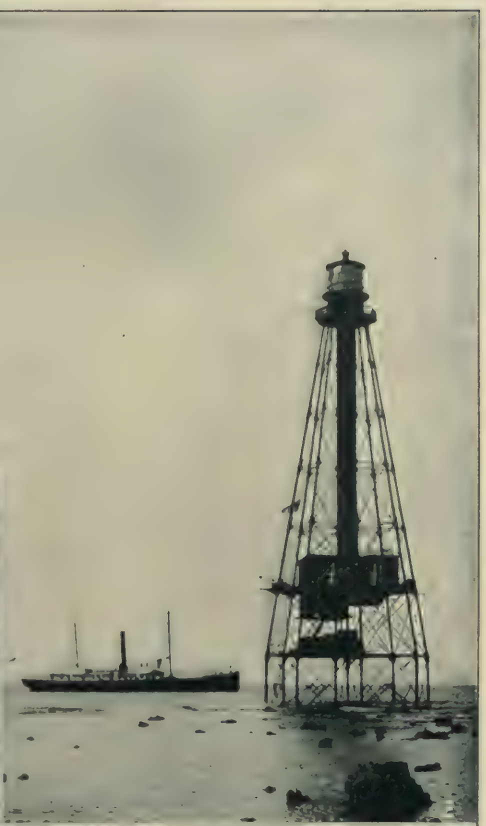
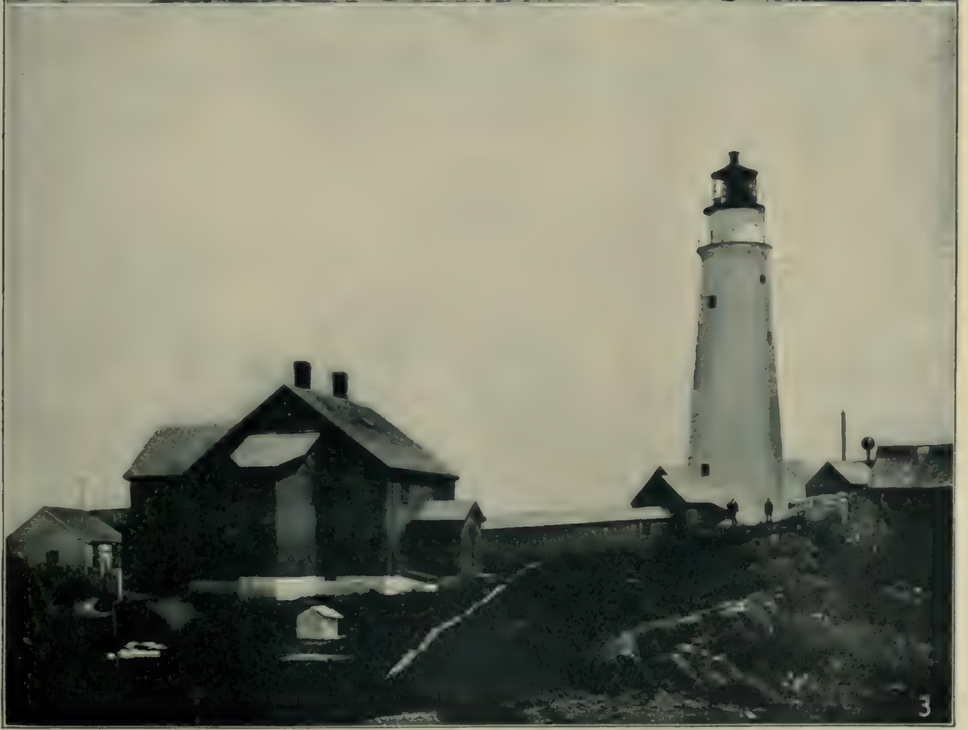
Faulty as Smeaton's design was in certain respects, it served as a model for lighthouse construction in masonry which has been followed in its general features ever since.

The Bell Rock Lighthouse, off the east coast of Scotland, is built upon a reef of rocks in the German Ocean, 11 miles from the coast, nearly opposite the Firth of Tay. The rock upon which it stands is red sandstone from 12 feet to 15 feet below spring tide, with from 2 feet to 4 feet exposure at low tide. The tower is also of sandstone, but the facing masonry for a height of 30 feet is granite. It was designed by the celebrated engineers Robert Stevenson and John Rennie and was modeled after the Eddystone Lighthouse of Smeaton. Its diameter at the base is 42 feet, and at the top beneath the cornice it is 15 feet. The stonework is 102½ feet high, and the top of the lantern is 115 feet high. Work was begun in 1807 and finished in 1810. The Skerryvore Lighthouse, off the west coast of Scotland, is built upon a cluster of rocks, the largest of which, known as Skerryvore rock, carries the lighthouse. The engineer was Allan Stevenson, who adopted a design for the tower resembling more nearly the frustum of a cone than did the Eddystone and Bell Rock towers. The tower is circular, 42 feet in diameter at the base, 16 feet in diameter at the top, and 138 feet high to the base of the lantern. Work was begun in 1838 and finished in 1842. Wolf Rock Lighthouse, situated on Wolf Rock between Scilly and Lizard Point, off the English coast, has a tower in the form of a concave elliptical frustum, 116½ feet high, 41⅔ feet in diameter at the base. It was begun in 1862 and finished in 1869.

The Héaux de Brehat Lighthouse is situated on the rock of the same name about 3 miles from the most northerly point of the peninsula of Brittany. It consists of a tower with an interior cylindrical opening 14 feet in diameter, 158 feet high from its base to the lantern floor. The tower consists of two parts—the lower part being a concave frustum and the upper part being nearly a true cylinder. The lighthouse of Ar-men, which is situated on one of a series of rocks off Cape Finisterre, France, is another masonry lighthouse of French design which is notable for its exposed situation and the consequent difficulties of construction. The height of the focal plane of the light is 96 feet above sea level. The lighthouse of Triagoz, in the Department of Nord, is another French example of exposed sea-rock lighthouse construction. The masonry tower is square and 92 feet high, with the focal plane of the light 6 feet above this height.





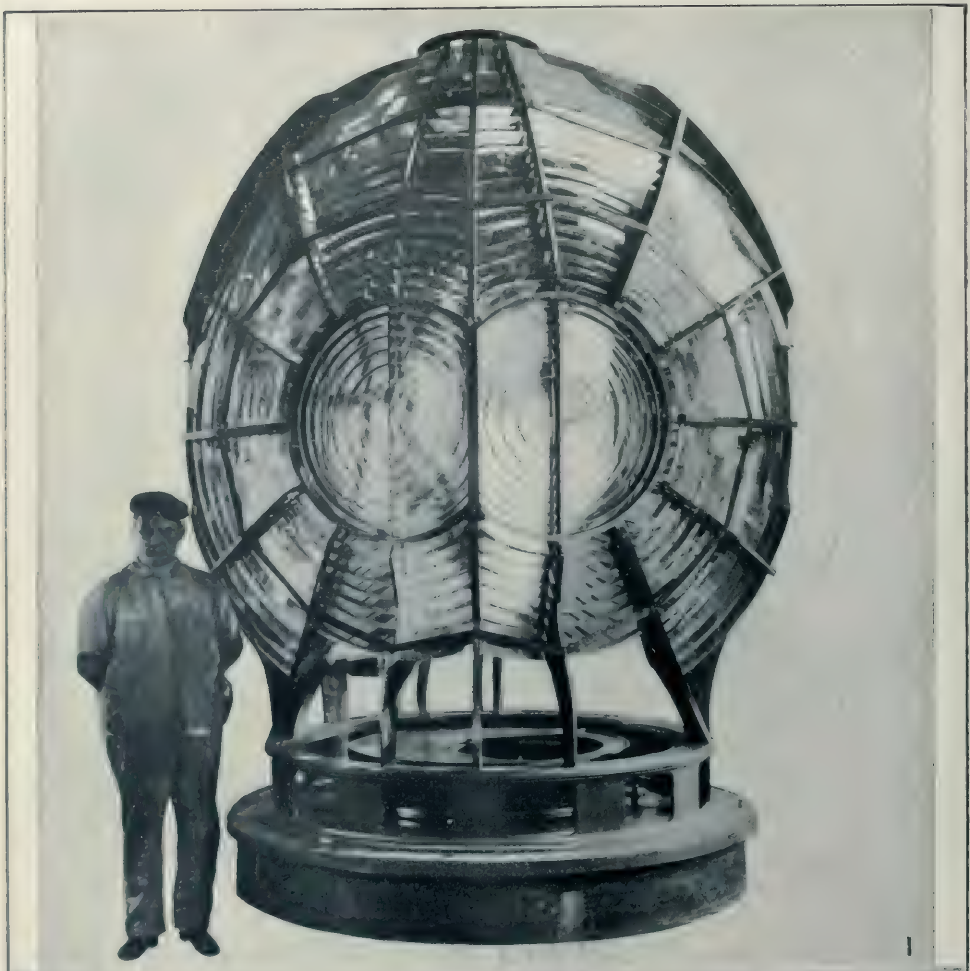


3

TYPICAL UNITED STATES LIGHTHOUSES

1. ROCK OF AGES LIGHT STATION, MICHIGAN. 2. SOMBRERO KEY LIGHT STATION, FLORIDA.
3. BOSTON LIGHT STATION, MASSACHUSETTS.

LIGHTHOUSES



1. **LENS, KILAUEA POINT LIGHT STATION, HAWAII.** A second order flashing lens of two groups, each of two panels, comprising seven refracting and seventeen reflecting prisms. The apparatus rotates on a mercury float driven by clock-work, and gives a double white flash every ten seconds, visible twenty-one nautical miles in clear weather. The light is furnished by an incandescent oil-vapor lamp.
2. **CAPE HATTERAS LIGHT STATION, NORTH CAROLINA.**

Another important light off the coast of Brittany, near Cape Finisterre, is that at Jument Rock at the island of Ushant. This is a circular masonry tower, 118 feet in height from water level to the focal plane of its lantern. Its construction was begun in 1904, and it was not completed until 1912, the total outlay for tower and lamp involving some 850,000 francs. The light shows red flashes in groups of three 15 seconds apart, and there is also an audible fog signal from a siren, which likewise consists of groups of three blasts. The tower, which is 36 feet in diameter at its base, has its foundation on solid rock, and the stones are strengthened by enormous tiebars, so as to secure the greatest possible stability. The masonry work involves some 61,800 cubic feet. The optical apparatus has six catadioptric panels each of an amplitude of 60° and 27.56 inches focal distance, and it is carried on a mercury float on a central axis. Incandescent gasoline lamps with mantles, 3.346 inches in diameter, supply illumination, and the power of the red flashes is stated at 3300 carcel burners, giving an illumination range of at least 20 miles during one-half the year and 7 miles during nine-tenths of the year.

Another interesting lighthouse of somewhat different construction was one built in 1908 at One-Fathom Bank on the Strait of Malacca, a reënforced concrete structure, which was founded on piles, driven through the sand to firm-bearing material. This was designed on the Hennebique system of reënforced concrete structure, with two rings of screw piles sunk in the sand and bound together at the top. On this a superstructure was built, so that a light can be maintained with its focal plane 925 feet above the water. The location was a most dangerous one, both for navigation and for the actual construction, as it was exposed to rough weather, with waves sometimes 8 feet in height, and a pronounced rise and fall of the tide. The lantern was raised above the superstructure, which contains the apartments for the keeper and supplies, and was carried on a superframing. It is a revolving light, giving groups of white flashes, and is visible 15 miles.

A light of different construction, built in 1909, at Cayo Caiman Grande, Cuba, consisted of a steel octagonal pyramidal tower, 115 feet in height, with a watchtower, surmounted by a lantern above, so that it was nearly 150 feet in height over all. At the base, which was 56½ feet in diameter, was located a house for the keeper of the light.

In the United States masonry lighthouse towers of notable character have been built at Minot's Ledge, Spectacle Reef, and Tillamook Rock. Minot's Ledge, off the town of Cohasset, in Massachusetts Bay, about 20 miles east-southeast of Boston, was one of the most dangerous places in the world before the establishment of a signal. The difficulties in the construction of a lighthouse upon this rock were immense. The first structure, which was of iron, was completed in 1849, but stood only until April, 1851, when it was demolished by a terrific storm. In 1852 money was appropriated by Congress for a new lighthouse, and work was commenced in 1855, but it was not till the latter part of 1857 that the first stone was laid. The structure was completed in 1860. It is a granite tower in the form of a frustum of a cone, having a base 30 feet in diameter, and a height of stonework of 88 feet, the lower 40 feet being solid. The courses are dovetailed and are fastened with wrought-iron dowels.

The lighthouse at Spectacle Reef, in the northern part of Lake Huron, was built not only to resist waves, but ice fields, often covering thousands of acres and moving at the rate of 2 or 3 miles per hour. That the structure should be able to withstand this force, it was so designed as to cause the ice to be broken and piled into a protecting barrier. The tower is the frustum of a cone, 32 feet in diameter at the base, and 18 feet just beneath the cornice at a height of 80 feet. The whole height of the stonework is 93 feet above the base, which is 11 feet below the surface of the water. The tower is solid as high as 34 feet, above which it contains five stories, each 14 feet in diameter. The work was commenced May 1, 1870, and the light was first used June 1, 1874. The cost was $375,000. Tillamook Rock is a bold isolated basaltic rock in the Pacific Ocean about a mile off Tillamook Head and 20 miles south of the Columbia River. The lighthouse on it, built in 1880–81, consists of a square masonry tower of no great height rising out of the centre of a masonry house 45 × 48 feet in plan, the tower proper being 16 feet square.

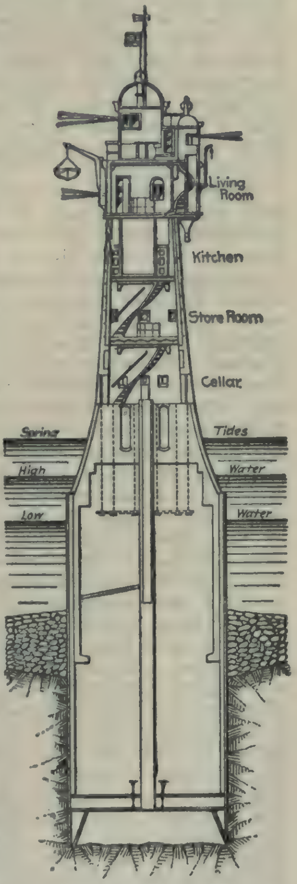


Fig. 2. VERTICAL SECTION SHOWING ROTHERSAND LIGHTHOUSE.

The lighthouses so far described were built upon solid rock, and the foundation problem was a simple one except for the work of combating the wind and waves. Another class of lighthouses of even more difficult construction comprises those structures which are located on shoals at long distances from the shore. Here the sinking of the foundations is a serious problem by itself, even were it not complicated by the dangers of wind and water. Perhaps the two most noted masonry towers erected on such foundations are the Rothersand Lighthouse, in the North Sea, Holland, and the Fourteen-Foot Bank Lighthouse, in Delaware Bay, United States. To build the foundation for the Rothersand Lighthouse a caisson, in plan resembling a section of a biconvex lens and built of boiler iron, was used. This caisson was 36 feet, 8 inches wide, 46 feet, 8 inches long, and 61 feet, 8 inches high. At a height of 8 feet, 4 inches above the bottom edge of this lenticular shell there was a transverse diaphragm forming the top of the working chamber. Above this diaphragm the caisson was divided into four stories—the lowest for mixing concrete, the second for the machinery installation, the third for sleeping and store rooms, and the fourth for the revolving steam cranes. The three upper floors were suspended from the caisson by screws so that they could be raised as the work progressed. The caisson was built on the shore, towed to its site, and sunk by the pneumatic process to a depth of 73 feet below low water. After being sunk the caisson was surrounded by a brush mattress 3 feet thick for a distance of 50 feet on all sides, to prevent the currents from scouring away the sand. The tower and lantern were then erected, and work was completed in 1885.

The Fourteen-Foot Bank Lighthouse was constructed by means of a pneumatic caisson, as was the Rothersand tower. The caisson proper was made of wood, square in plan, and surmounted by a cylindrical cast-iron shell 35 feet in diameter, which, filled with concrete, formed the light tower. The structure was completed in 1887. Cast-iron, concrete-filled, cylindrical lighthouse towers have been constructed in several locations upon rock foundations. The first cast-iron lighthouse ever erected was at Point Morant, Jamaica, in 1842. The tower was built of nine tiers of plates, ¾ of an inch thick and 10 feet high, held together by bolts and flanges on the inside, and then filled in with masonry and concrete to the height of 27 feet. It rests upon a foundation of granite and rises to a height of 96 feet. It is 18½ feet in diameter at the base and 11 feet at the top.

A form of lighthouse at one time extensively used was constructed on what is called the screw-pile system, an invention of Alexander Mitchell, who with his son laid the foundation of the lighthouse on Maplin Sand at the mouth of the Thames, England. Two similar structures followed, Chapman Head in 1849 and Gunfleet in 1850, also near the mouth of the Thames. Other screw-pile lights were afterward erected in different parts of Great Britain. The great feature of the screw pile is that the piles upon which the structure rests are in the form of screws and are driven in the sand or soil to a sufficient depth in the manner of a corkscrew. The first screw-pile lighthouse erected in the United States was by Col. Hartman Bache, United States Engineer Corps, at Brandywine Shoal, Delaware Bay, 8 miles from the ocean, in 1847–50. This in 1914 was replaced by a reënforced concrete caisson structure. The screw-pile lighthouse at Sand Key, Florida Reefs, is supported on 16 piles, with an auxiliary pile in the centre to support the staircase, making in all 17. They are 8 inches in diameter, with a screw of 2 feet in diameter at the lower ends, which are bored 12 feet into the reef. The framework of the tower consists of cast-iron tubular columns framed together, having wrought-iron ties at each joint and braced diagonally on the faces of each tier. The keeper's house is supported by cast-iron girders and joists 20 feet above the foundation. The focal plane is 109 feet above mean high water. The foundation is 50 feet in diameter.

United States Lighthouse Service. The first lighthouse in North America was built in 1715–16, at the entrance to Boston harbor, by the Province of Massachusetts, and was supported by light dues on all incoming and outgoing vessels, except coasters. Several other lighthouses were built by the Colonies. Congress by the Act of Aug. 7, 1789, authorized the maintenance of lighthouses and other aids to navigation at the expense of the United States. There were at that date eight lights in operation, maintained by the Colonies. These, together with others completed later, 13 in all, were ceded to the general government by the States. The maintenance of lighthouses, buoys, etc., was placed under the Treasury Department and up to 1820 was directed personally by the Secretary of the Treasury, except for two intervals, when supervision was assigned by him to the Commissioner of Revenue. In 1820 the superintendence of the lights devolved upon the Fifth Auditor of the Treasury, who was popularly known as the General Superintendent of Lights, and who continued in charge thereof until 1852, when the United States Lighthouse Board, consisting of officers of the navy and army and civilians, was organized, with the Secretary of the Treasury as ex-officio president of the board. The board selected from its own number a member to act as chairman.

The Lighthouse Service was transferred to the Department of Commerce on July 1, 1903. On July 1, 1910, the Lighthouse Board was terminated, and the present Bureau of Lighthouses established, under the Commissioner of Lighthouses, an officer appointed by the President, whose office is in Washington, which is the executive centre of the service. The service outside of Washington is divided into 19 lighthouse districts, each of which is under the charge of a lighthouse inspector. In each district there is a central office at a location selected on account of either its maritime importance or its geographical position, and there are also one or more lighthouse depots located conveniently for carrying on the work of the district in the matter of storing and distributing supplies and apparatus. Each district is provided with one or more lighthouse tenders for the placing and care of the buoyage system in the district, for distributing supplies to the various light vessels and inaccessible stations, for the transportation of materials for construction and repair when ordinary means are not available, and for transporting the inspector and other officers of the service on official inspections. In addition to the various district depots there is also in New York harbor a general lighthouse depot where many of the supplies for the whole service are purchased and sent out for distribution, and where much of the special apparatus of the service is manufactured or repaired, and where also there is carried on various technical work, such as testing apparatus and supplies and designing or improving apparatus.

The construction of lighthouses in the United States varies greatly. Almost all the usual materials of construction have been employed, such as stone masonry, brickwork, reënforced concrete, framed timber, structural cast iron, structural steel, cast-iron plates, steel plates, and piping. Light stations situated on land sites usually consist of the light tower, oil house, fog-signal building, keepers' dwellings, workshop, water-supply and drainage systems, boathouse and ways, barn, and the usual outbuildings, roads, and walks, although, owing to the restricted area of some sites, one or more or all of the buildings may be combined in one. On submarine sites the whole station is practically confined to one structure.

For land sites, the foundation for a closed tower of masonry, or metal work, is usually a single block of concrete resting upon the foundation soil. Occasionally these blocks are placed upon a timber grillage supported by piles for sites upon low or marshy land. In all cases the block is extended so as to bring the unit pressures within the bearing power of the soil. Occasionally a skeleton structure is placed upon a single foundation block, but usually each column or leg of the tower has its individual block. Where the site is subject to overflow, the buildings are sometimes grouped together, raised upon braced columns and connected by a system of galleries.

For submarine sites, the foundation may consist of a cylindrical cast-iron or sheet-steel caisson filled with concrete, or a masonry pier. Cast-iron caissons are in general use on the Atlantic coast. When placed upon a ledge of rock, the latter is usually leveled up with concrete bags if below low water, or with tools if exposed, and the ledge or rock is then heavily ragbolted to the concrete filling. For soft bottom, the best method of procedure is to float the caisson out and sink it by the pneumatic process. Both timber and metal-working chambers have been used, and the depths from the cutting edge to high water have varied from 19 to 85 feet. Other foundations, consisting of timber cribs and concrete blocks, used in fresh water, have been placed either directly on good existing bottom or upon a layer of small rock, usually 3 or 4 feet thick, deposited upon the soft or dredged bottom prior to floating the crib out. These timber cribs are usually filled with stone and terminate about 2 feet below low-water level; the concrete blocks are then placed to the height of the deck.

Structures upon land sites are exposed to wind pressures and occasionally to waves in addition. Those upon submarine sites are exposed to wind, wave, currents, and ice. The usual procedure in determining the stability of tower is to locate the common centre of effort of all the forces acting upon the structure to overturn it and so proportion the weights of the entire structure (the buoyancy of the water must be taken into account for submarine structures) that the resultant of the active forces and the net weight falls so far within the outer edge of the base that there is compression over its whole surface if the foundation soil is compressible. In seeking for this result it is proper to include the lateral resistance of the soil when the structure penetrates it for some distance for the reason that it is often heavily compressed by a large deposit of riprap and offers good support. The maximum unit pressures, both vertical and lateral, must not exceed the bearing power of the soil. In case the foundation is rock, the resultant must fall so far within the outer edge of the base that the maximum unit pressure does not exceed the compressive strength of the materials in contact.

The wind, wave, current, and ice pressures assumed should be the maximum in each instance, as lighthouses are commonly exposed to severe gales and flows of ice. It has been the practice to assume wind pressure for flat surfaces at 60 pounds per square foot, allowing two-thirds of this figure for rotundity. Maximum wave pressures of 6000 pounds per square foot on flat surfaces are assumed, based upon Stevenson's experiments, the force of the wave being greatest at its crest and diminishing to zero at its base. The pressures exerted by currents vary with their rate of speed. The pressures due to ice have been assumed at 30,000 pounds per square foot for a field of melting ice, 1 foot thick, striking the pier and crushing its way past.

The superstructures of all towers, whether separate or combined with other buildings, have certain features in common. There is a main entrance door at the base, a flight of winding stairs, broken by landings in high structures, leading to the service room, which in the larger lights is usually separated by an air lock from the watch room above, the latter supporting the lantern. Occasionally in large lights and usually in small ones the service and watch rooms are combined. The pedestal of the illuminating apparatus usually rests upon the watch-room floor, but in the small lights the lantern floor supports it. The clear glazed opening of the lantern is just sufficient to pass the horizontal rays from the illuminating apparatus, and if the latter is of a revolving type, showing flashes or occultations, the newel post of the tower serves as a weight shaft for the clock. There are railed galleries outside both lantern and watch room. The tower should be thoroughly fireproof and isolated in this respect from the other buildings. For calculating the strength of closed and skeleton towers the manner prescribed for chimneys and viaduct bents is employed, with the exception that great stiffness and rigidity must be provided, as vibrations are detrimental to the proper working of the lamps and clocks of the illuminating apparatus.

Lighthouse Illumination. In considering the ranges of visibility both the geographical range of the light due to its height above sea level and the luminous intensity of the light emitted by the illuminating apparatus must be taken into account. The geographical range, or the distance corresponding to the height, may be found approximately by the formula $D = \frac{8}{7}\sqrt{H}$, in which $H =$ the elevation, or height, in feet, of the object above sea level, and $D =$ the corresponding distance of visibility, in nautical miles. The formula is based on the mean curvature of the earth and is corrected for ordinary atmospheric refraction and should be used only for moderate distances and elevations. The intensity of a light as observed, affecting the luminous range, may be greatly lessened, or the light may be made invisible by unfavorable conditions due to fog, haze, rain, or smoke.

Lights have hitherto been classified according to their order. The order of a light depends upon the inside radius, or focal distance of the lens, i.e., the distance from the centre of the light to the inner surface of the lens, but does not apply to ordinary metallic or glass reflectors, nor to unclassified lenses smaller than 6th-order illuminating apparatus. The table on the following page shows the focal distances of standard sizes of illuminating apparatus. There are also miscellaneous smaller lights for less important localities. The power of the lights does not vary directly with the order excepting where the apparatus and illuminant are similar. The designation of lights by orders is therefore somewhat obsolete, and recent practice in the United States substitutes the candle power of the light, from which the mariner may more readily judge of the relative brilliancy and power of the various lights.

Illuminating apparatus is, as a rule, of three general characters, viz., catoptric or reflecting, dioptric or refracting, and catadioptric, in which the lenticular apparatus is provided with both reflecting and refracting media. The latter type is the most in use. In the *catoptric* or *reflecting system* all of those rays proceeding from the focus of a parabolic mirror which fall upon its surface are reflected parallel to the axis so as to form a solid beam of light. As the property of the parabolic reflector is to collect the rays incident upon its surface into one beam of parallel rays, it would be absolutely impossible, were the flame from which the rays proceeded a mathematical point, to produce a light which would illuminate the whole of the horizon, unless there were an infinite number of reflectors. (See PARABOLA.) But as the radiant, instead of being a mathematical point, is a physical object, consisting of a flame of appreciable size, the rays which come from the outer portion of the luminous cone proceed, after reflection, in such divergent directions as to render it practically possible to light up, though unequally, the whole horizon. The distinction of a red light is produced by using a chimney of red instead of white glass for each burner.

	Millimeters	Inches
1st order	920	36.2
2d order	700	27.6
3d order	500	19.7
3½ order	375	14.7
4th order	250	9.8
5th order	187.5	7.4
6th order	150	5.9

The *flashing* light, giving, by revolutions of the lens, flashes at prescribed intervals, which is one of the most striking of all the distinctions, was first introduced by Robert Stevenson, the well-known lighthouse engineer, in 1822, at Rhinns of Islay in Argyllshire. The same engineer also introduced what has been called the *intermittent*, now known as occulting, light, by which a stationary frame with reflectors is instantaneously eclipsed and is again as suddenly revealed to view by the vertical movement of opaque cylinders in front of the reflectors. The intermittent is distinguished from the revolving light, which also appears and disappears successively to the view, by the suddenness of the eclipses and of the reappearances, whereas in all revolving lights there is a gradual waxing and waning of the light. Wilson introduced at Troon harbor an intermittent light which was produced by a beautifully simple contrivance for suddenly lowering and raising a gas flame. Stevenson proposed an intermittent light of *unequal periods* by causing unequal sectors of a spherical mirror to revolve between the flame and a fixed dioptric apparatus (such as that shown in Fig. 3). The power of the light is increased by the action of the spherical mirror, which also acts as a mask in the opposite azimuths.

Another method of bending the divergent rays proceeding from a lamp into such directions as shall be useful to the mariner is that of *refraction*, known as the *dioptric system*. If a flame be placed in the focus of a lens of the proper form, the diverging rays will be bent parallel to each other, so as to form a single solid beam of light. Fresnel was the first to propose and to introduce lenticular action into lighthouse illumination, by the adoption of the annular or built lens, which had been suggested as a burning instrument by Buffon and Condorcet. He also, in conjunction with Arago and Mathieu, used a large lamp having four concentric wicks. In order to produce a *flashing* light on the lenticular or dioptric system, a different arrangement was adopted from that already described for the catoptric system. The large lamp was now made a fixture, and four or more annular lenses were fitted together, so as to form a frame of glass which surrounded the lamp. When this frame is made to revolve around the lamp, the mariner gets the full effect of the lens whenever its axis is pointed towards him, and this full light fades gradually into darkness as the axis of the lens passes from him. In order to operate on those rays of light which passed above the lens, a system of double *optical* agents was employed by Fresnel. These consisted of a pyramid of lenses with mirrors placed above at the proper angle for rendering the rays passing upward parallel to those which came from the annular lens. But Fresnel did not stop here, for, in order to make the lenticular system suitable for fixed as well as revolving lights, he designed a new optical agent, to which the name of *cylinder refractor* was given. This consists of cylindrical lenses, which were the solids that would be generated were the middle vertical profile of an annular lens made to revolve around a vertical axis. The action of this instrument is obviously, while allowing the rays to spread naturally in the horizontal plane, to suffer refraction in the vertical plane. The effect of this instrument is, therefore, to show a light of equal intensity constantly all around the horizon and thus to form a better and more equal light than that which was formerly produced for fixed lights by parabolic reflection. It is obvious, however, from our description that the diverging rays which were not intercepted by this cylindric hoop, or those which would have passed upward and been uselessly expended in illuminating the clouds, or downward in uselessly illuminating the light-room floor, were lost to the mariner; and to render these effective Fresnel ultimately adopted the use of what has been called the internal or total reflection of glass; and here it is necessary to explain that one of the great advantages of internal reflection by glass over metal is the smaller quantity of light that is absorbed. It has been ascertained that there is a gain of nearly one-fourth (0.249) by employing glass prisms instead of metallic reflectors for lighthouse illumination. There were introduced above and below the cylindric refracting drum separate glass prisms of triangular section, the first surface of each of which refracted to a certain extent any ray of light which fell upon it, while the second surface was placed at such an angle as to reflect, by total reflections, the ray which had before been refracted by the first surface; and the last or outer surface produced another refraction, which made the rays finally pass out parallel with those refracted by the central cylindric drum. The light falling above the cylindric drum was thus by refractions and reflections bent downward, and that falling below was bent upward, so as to be made horizontal and parallel with that proceeding from the refracting drum. Fig. 3 represents in vertical section this, which is the most perfect of Fresnel's inventions in lighthouse illumination, especially when made in pieces of the rhomboidal form and used in connection with a diagonal framing introduced by Allan Stevenson. In Fig. 3 *p* shows the refracting and totally reflecting prisms, *r* the cylindric refractor, and *f* the radiant. From what has been stated, it will be readily seen that, in so far as regards fixed lights, which are required to illuminate *constantly* the whole of the horizon with equal intensity, the dioptric light of Fresnel with Allan Stevenson's improvements is an improved instrument. But the case is different as regards revolving lights, or those where the whole rays have to be concentrated into one or more beams of parallel rays. To revert to the parabolic reflector, it must be obvious that all rays which escape past the lips of the reflector never reach the eye of the mariner, while, if we return to the dioptric revolving light of Fresnel, we find that those rays which escape past the lens are acted on by *two* agents, both of which cause loss of light by absorption. The loss occasioned by the inclined mirrors and in passing through the pyramidal inclined lenses was estimated by Fresnel himself at *one-half* of the whole incident rays. In order to avoid this loss of light Thomas Stevenson proposed in 1849 to introduce an arrangement by which the use of one of these agents is avoided, and the employment of the total reflection which had been successfully employed by Fresnel for fixed lights was introduced with great advantage for revolving lights. He combined an annular lens, *L* (Fig. 4); a parabolic conoid, *a*, truncated, at its parameter, or between that and its vertex; and a portion of a spherical mirror, *b*. The lens and mirror were placed at the proper focal distance from the flame, so that all the rays of light coming from the front of the flame were intercepted either by the paraboloid or the lens. The rays emanating from the flame may be regarded as divided into two hemispheres. The lens intercepts part of the anterior hemisphere of rays and makes them parallel, while the remainder fall on the paraboloidal surface and are reflected parallel. The rays forming the posterior hemisphere falling on the spherical mirror are reflected forward again through the focus in the same lines, but in opposite directions to those in which they came, and then are in part refracted by the lens, and the rest are made parallel by the paraboloid. The result is that rays finally coming from the posterior hemisphere emerge horizontally combined with those from the anterior hemisphere. Thus the entire sphere of diverging rays is collected into one beam of parallel rays without employing any unnecessary agents.

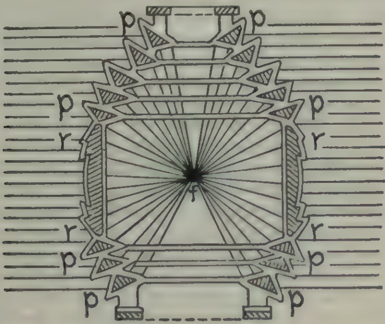

FIG. 3. VERTICAL SECTION OF FRESNEL SYSTEM.

What has been just described was termed by Stevenson a *holophote*. What follows is a description of the *catadioptric* system in which total reflection is the underlying principle. The front half of the rays is operated upon by totally reflecting glass prisms, similar in section to those applied by Fresnel for fixed lights; but, instead of being curvilinear in the horizontal plane only, they are also curvilinear in the vertical plane and thus produce, in union with an annular lens, a beam of parallel rays similar to what is produced by the parabolic mirror. The rays proceeding backward fall upon glass prisms, which produce two reflections upon each ray and cause it to pass back through the flame, so as to fall ultimately in the proper direction upon the dioptric holophote in front, so that the whole of the light proceeding from the flame is thus ultimately parallelized by means of the smallest number and the best kind of optical agents. It is a remarkable property of the spherical mirror that no ray passes *through* it, so that an observer, standing behind the instrument, perceives no light, though there is nothing between him and the flame but a screen of transparent glass. Where the light is produced by great central stationary burners, the apparatus assumes the form of a polygonal frame, consisting of sectors of lenses and holophotal prisms, which revolves round the flame, and each face of which produces a beam of parallel rays. Hence, when the frame revolves round the central flame, the mariner is alternately illuminated and left in darkness, according as the axis of each successive face is pointed towards him or from him. In the revolving holophotal light one agent is enabled to do the work of two agents in the revolving light of Fresnel, as total reflection, or that by which least light is lost, is substituted for metallic reflection. The catadioptric holophotal system, or that by which total reflection is used as a portion of the revolving apparatus, was first employed on a small scale in 1850 at the Horsburg Lighthouse, and on a large scale in 1851 at North Ronaldshay in Orkney. Since that date this system has been all but universally introduced into Europe and America.

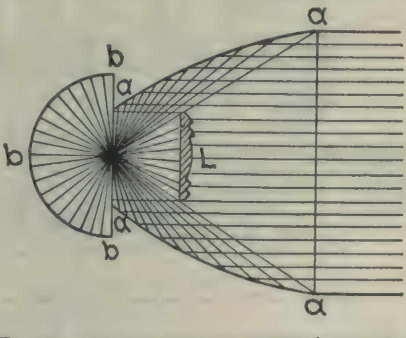

FIG. 4. PLAN OF THOMAS STEVENSON'S SYSTEM.

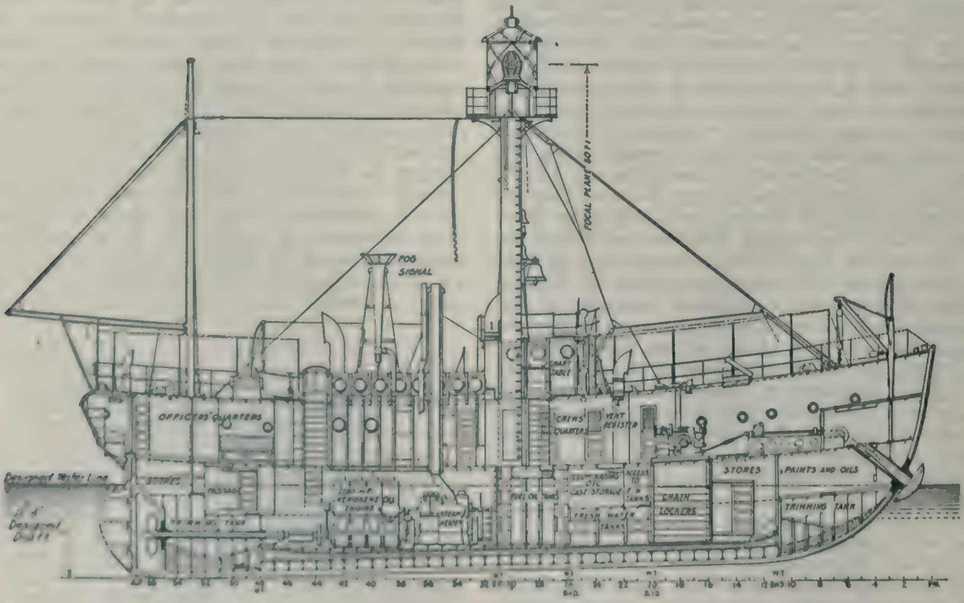
Much of the coast of the United States was lighted before the introduction of modern lighthouse apparatus, and therefore the older lights were in general fixed lights. The more important of these have been replaced by flashing or occulting apparatus, and such improvements are being made continuously from time to time. The more common characteristics of lights are as follows: *fixed,* continuous steady light; *flashing,* showing a single flash at regular intervals, or a steady light with total eclipses; *fixed and flashing,* a fixed light varied at regular intervals by a single flash of greater brilliance—the flash is preceded and followed by a diminution of light or an eclipse; *group flashing,* showing at regular intervals groups of flashes; *occulting,* a steady light suddenly and totally eclipsed at regular intervals; *group occulting,* a steady light suddenly and totally eclipsed by a group of two or more eclipses. Lights are characterized as flashing or occulting solely according to the relative duration of light and darkness, and without reference to the type of illuminating apparatus employed or relative brilliancy, a flash being shorter than the duration of an eclipse, and an occultation shorter than or equal to the duration of light.

All of the foregoing applies more particularly to lights which do not change color, but other combinations may be obtained by showing alternately white and colored lights in various sequences. Such lights are known as alternating. Such lights of alternating colors should be so designed that the white and colored rays are of equal intensity. In modern practice fixed lights are, if practicable, usually avoided for important stations on account of the liability of confusion with neighboring private lights. Fixed and flashing lights and lights with prolonged flashes are also generally avoided, for the reason that the fixed and prolonged rays emitted by the lenticular apparatus are of less intensity than those of the flashes, giving a variable characteristic on account of the difference of luminous range, which may be misleading at the outer limit of visibility. In former times twin or other multiple lights were used for distinguishing purposes; but they are now considered obsolete, as they largely increase the cost of maintenance and are less distinctive than flashing lights.



DESIGN FOR UNITED STATES LIGHT VESSELS FOR USE ON ATLANTIC COAST. (From *Engineering News.*)

Fog Signals are devices employed to give warning during fog or thick weather when lights are obscured, and are installed at all important light stations. They consist in general of some sound-producing apparatus arranged to give a definite number of strokes or blasts per minute or other unit of time. Fog signals are either bells struck by hand or machinery, submarine bells struck by machinery, or whistles, reed horns, or sirens blown by compressed air or steam. Aërial fog signals are subject to some uncertainty, as sound is conveyed irregularly through the atmosphere, and it is not always possible to judge distance from a fog signal by the power of the sound. Under certain conditions of the atmosphere the sound may be lost a short distance from the station, as there may be silent areas or zones, or the sound may carry much farther in one direction than in another, and these conditions may vary in the same locality within short intervals of time. Submarine signals have, as a rule, a more uniform and effective range of audibility, but these are sometimes affected by irregularity of the sea bottom.

Light Vessels are vessels fitted with lights moored at sea at important points off the coast, the approaches to harbors, or in the vicinity of reefs, where it is not feasible to erect lighthouses. Prior to 1807 the lantern was hung at the yard-arm. Robert Stevenson then introduced a system of lanterns, grouped around a copper tube around the vessel's mast, which passed through the tube. In this way proper optical appliances could be employed, and the lantern lowered on the mast so as to pass through the roof of a house on the deck, where the lamps are filled or trimmed. In 1864 six floating lights were constructed for the Hugli under the direction of the Messrs. Stevenson, in which the dioptric principle was applied. Eight suspended lamps with spherical mirrors behind were placed in the lantern round the mast so as to show in every azimuth rays from three of them at once. In 1914 the United States maintained light vessels on 52 stations and had for this purpose 66 light vessels, of which 14 were relief vessels. Recent light vessels carry one steel lantern mast of a diameter sufficient to contain a ladder giving access to the lantern, in which is housed lenticular apparatus similar to that used in lighthouses. Modern light vessels for exposed stations are also provided with full power-propelling machinery and fitted throughout with all modern appliances, such as steam windlass, sanitary plumbing and fixtures, electric-lighting system, and radiotelegraph. Light vessels are also equipped with powerful fog signals and bear on the sides a brief marking name in large letters to insure maximum visibility. Light vessels on United States coast stations also display the International Code Signal of their station whenever a vessel is approaching or in the vicinity and there are indications that such vessel is in strange waters or fails to recognize the station, or when the vessel asks for the information.

Sources of Light. The illuminant of the United States Lighthouse Service has been changed frequently. Fires in open braziers and tallow candles were used in early lighthouses abroad, but oil lamps were soon used in America, if not from the first lighting of Boston Light. Tallow candles were used at Boston harbor in 1716. Fish oil was burned in spider lamps, and afterward sperm oil was burned in a sort of argand lamp in Winslow's magnifying and reflecting lanterns, which remained in use up to the time of the establishment of the Lighthouse Board. As sperm oil became more and more expensive, the attention of the board was directed to finding cheaper illuminant, and it was found that colza, the oil expressed from the seeds of wild cabbage and several other plants, which was largely used in France and Great Britain, would fulfill all the conditions except that of being of home production. This was overcome by stimulating the cultivation of the plants and the manufacture of the oil from the seeds as a private industry. Further experiments with lard oil were made, with such process as to prove that the latter oil of a certain grade was a more desirable illuminant than colza, as it was more certain in quantity and production and was more economical in price. This became the next established illuminant. The use of petroleum had attracted attention for a long time, and in 1855 the United States Lighthouse Board made some unsuccessful experiments with it. Meantime the price of lard oil had so increased that some other illuminant became a necessity, and, as kerosene in one form or another was in successful use in European lighthouses, the board renewed its experiments with petroleum. The first difficulty was that of the lamp in which it should be burned. This was finally overcome by the board, which succeeded in producing a lamp in its own laboratory that proved satisfactory and that was introduced into the lighthouses. Practically all of the important coast stations now use kerosene as the illuminant, by means of the incandescent oil-vapor system. The plant at each station consists, briefly, of a tank containing the kerosene under high air pressure maintained by hand pump and the proper tubing through which the oil is forced from the tank to the lamp, which consists of a vaporizer, Bunsen burner, and a mantle under which the vaporized oil is burned, producing a brilliant incandescence. Other forms of illuminant are also used in selected localities, such as compressed-oil gas or acetylene, and self-generating acetylene apparatus by the use of calcium carbide. Electric light is also used when conditions warrant, and the most powerful light now maintained by the United States Lighthouse Service is that at Navesink, at the entrance to New York Bay, which consists of an electric arc exhibited through a modern lenticular apparatus, giving a white flash every five seconds, with an estimated candle power of 25,000,000.

Buoys. Buoys are extensively used for marking channels, dangerous and salient points. In the United States the following order is prescribed by law for the coloring and numbering of buoys along the coasts or in bays or channels, viz., in approaching from the seaward red buoys with even numbers will be found on the starboard (right) side, and black buoys with odd numbers on the port (left) side. Buoys painted with red and black horizontal stripes will be found on obstructions, with channel ways on either side of them, and may be left on either hand when passing in. Buoys painted with black and white perpendicular stripes will be found in mid-channel and to avoid danger should be passed close to. In recent years the application of gas as an illuminant has greatly extended the usefulness of lighted buoys. Buoys with sound signals are also of value and are used in connection with either lighted or unlighted buoys. These are either whistling or bell buoys and are sounded automatically by the action of the sea. Therefore in calm weather they are less effective and at times may not be heard.

Lighted Beacons. Recent improvements in the United States Lighthouse Service have been made by the introduction of non-attended beacon lights, burning acetylene or oil gas stored in suitable containers under pressure. A flashing mechanism in the lantern, operated by the pressure of the gas, may be adjusted to give the light and dark periods desired, in connection with a small pilot light which burns continuously. As a rule, such lights require attention at periods varying from three months to a year and are therefore of value in remote localities, as they dispense with the necessity of keepers.

Statistics. The number of aids to navigation maintained by the United States Lighthouse Service on June 30, 1914, is shown in the following table:

Lighted aids:	
Lights (other than minor lights)	1,590
Minor lights	2,791
Light-vessel stations	52
Gas buoys	453
Float lights	118
Total	5,004
Unlighted aids:	
Fog signals	519
Submarine signals	48
Whistling buoys, unlighted	86
Bell buoys, unlighted	233
Other buoys	6,330
Day beacons	1,978
Total	9,194
Grand total	14,198

LIGHTHOUSE BUREAU. See LIGHTHOUSE.

LIGHT'NING (ME. *lightnyng*, illumination, from *lighten*, light). A brilliant flash of light between clouds or between a cloud and the earth. These flashes were shown by Benjamin Franklin to be simply enormous electrical discharges. The length of such a flash may be several miles. When the flashes are between the lower clouds and the earth, they are comparatively narrow and brilliant and are accompanied by thunder, but when they take place in the upper cloud region they become more diffuse, and thunder is rarely heard. Three general classes of lightning are recognized. The first of these is popularly and generally designated *forked, zigzag*, or *chain lightning*, which is a line of light of intense brilliancy, appearing to the eye as a single blinding streak of light, which sometimes breaks into one or two branches and is often a rosy or violet tint. Photography discloses, however, that the line of light is never actually zigzag, but is always instead of an irregular sinuous character. The second class of lightning is called *sheet lightning;* this has no definite form. It is generally of a rosy or red tint and appears in the distant horizon lighting up the clouds, dust, or haze in the atmosphere. The ordinary appearance of sheet lightning is very common, being due to the illumination of the clouds and haze by flashes of lightning which may be beyond the horizon, or concealed from direct view by intervening clouds, and thus become manifest although at a great distance. The third kind of lightning is the so-called *ball lightning*, which is said to appear like a small globe of brilliant light moving slowly through the air at a short distance above the ground or even rolling along the ground itself. Reliable observers have stated that on some occasions ball lightning has been seen to roll slowly into a house through an open door or window; it generally breaks up with an explosion, which, however, is not very destructive or dangerous. The descriptions of this phenomenon present many points difficult to understand, and it is only of late years that electricians have been willing to admit that we have here a true but peculiar form of electric discharge that demands further experimental investigation. Very minute discharges analogous to ball lightning have been produced in the physical laboratory. The silent electric discharges known as St. Elmo's fire (q.v.) are not usually included under lightning.

The thunder that accompanies lightning seems to be satisfactorily explained by the fact that the electric discharge in forcing its way through the atmosphere heats the air and the vapor lying in its path to a very high temperature, causing a very violent expansion along the whole length of the flash. The result is a very steep compression wave or, what is the same thing, a noise. Rapid cooling undoubtedly follows the heating, but the cooling is the less rapid and probably is not involved in the noise of thunder. Owing to the refraction of sound as it travels through the atmosphere, and especially the irregular refraction due to the temperature and wind, thunder does not travel very far before it begins to rise above the ground, so that observers frequently see flashes of lightning without hearing the thunder which has passed over their heads. Thunder is therefore rarely heard at a distance of 15 or 20 miles, whereas discharges of artillery may be heard 30, 50 or 100 miles.

Beginning with the researches of the late Prof. Ogden N. Rood, of Columbia College, and with the results obtained from the recent applications of photography, a few definite facts have been added to our knowledge of the nature of lightning. Professor Rood was able to show that a so-called single flash which may last several tenths of a second is simply an irregular succession of elementary flashes each of which lasts but a few thousandths of a second, or even less. Prof. John Trowbridge, of Harvard University, has constructed a storage battery of minute cells, by means of which he has been able to imitate true lightning flashes of several yards in length. Prof. Joseph Henry was able to show that all electric discharges are of an oscillating or alternating nature. The individual oscillations take place in a few millionths of a second and rapidly die away in intensity, so that the whole discharge is accomplished in a very short time, depending on the size and distance of the electrified bodies. Now, as lightning is evidently a simultaneous discharge from myriads of electrified drops towards numerous spots on the earth's surface, or towards a similar electrified cloud at a distance, it is therefore a rational hypothesis to assume that the numerous discharges observed by Rood as constituting one flash were simply a grand example of Henry's oscillatory discharges. The truth of this hypothesis seems to be confirmed by many photographs of lightning that have been taken within the past 15 years. Some good arguments against the oscillatory and favoring the direct character of lightning have been revealed recently by photographs with moving cameras, and the oscillograph. The latter instrument has not yet finally proved lightning to be oscillatory. (Consult Marvin, in *Monthly Weather Review*, vol. xiv, Washington, 1914.) Photographs of lightning sometimes show a dark flash among the bright ones, but this is now known to be a photochemical effect on the sensitive plate and not an electrical or atmospheric one. A fine example is shown in Fig. 1: The phenomenon is known as the "Clayden effect." Consult A. W. Clayden, *Philosophical Magazine*, vol. xxviii, also R. W. Wood, *Science*, vol. x. Wood shows that when a very intense flash of light acts upon a photo-

PHOTOGRAPHS OF LIGHTNING MADE AT SPOKANE, BY C. R. LEWIS, JULY 13, 1914

1. Photographic record of four probably simultaneous flashes secured at one exposure.
2. Photograph made subsequent to No. 1 from same point of view.
3. A later flash.
4. A still later flash.

In each case the shutter of the camera remained open from two to several minutes before any flash was observed and was then instantly closed.

graphic plate for a very short time (one fifty-thousandth of a second in actual experiments) and the plate is subsequently slightly fogged by short exposure to a feeble light (candle or equivalent) the image of the flash will be reversed and *in the print* will appear darker than the background. The branches and fainter flashes in some lightning prints therefore appear dark.

A good example of ribbon lightning is shown in Fig. 2. Such a ribbon might be due to unintentional displacement of the camera during the flash. Undoubtedly many reported cases may be thus explained away, but there remain a number of authentic ribbon-lightning records.

Two distinct explanations have been offered of authentic multiple flashes as seen in photographs. According to one, the first flash makes, as it were, a hole in the air, and succeeding discharges quickly pass up and down through this tube, while the general wind of the atmosphere carries it along for a few feet. According to the other explanation, the hole or tube of rarefied air lasts so short a time that the motion of the wind is inappreciable, but it is of such a great diameter that the successive discharges passing up and down within it side by side, or one within the other, appear as separate streaks of light. Neither of these explanations can be said to be satisfactory. Somewhat similar flashes can be produced artificially by blowing across a discharge between two electrodes.

The researches of Trowbridge and others have shown that the resistance of atmospheric air to electrical discharges becomes less as the voltage increases beyond some high number such as a million volts. Discharges in rapid succession from the same points progressively ionize a path which when completed conducts the perfect lightning spark. This has been beautifully demonstrated with the aid of a moving camera, by Walter, of Hamburg, and Larsen, of Chicago. Under powerful electric stress a resisting medium seems completely to lose its power of resistance and is immediately ruptured.

The frequency of occurrence of lightning and thunderstorms was published regularly in the *United States Monthly Weather Review* for a number of years, and the annual summary shows that the number of days on which thunderstorms were reported varies from 100 at any station in Louisiana and Florida to 5 or even 1 per annum at special stations in Arizona, California, Maine, Nevada, North Dakota, Oregon, and Washington. It is suspected that there is some relation between the aurora and the lightning, since on many occasions numerous thunderstorms have been recorded around a central region where clear skies and auroras were observed. Consult: Sir Oliver Lodge, *Lightning Conductors and Lightning Guards* (London, 1892); Alexander McAdie, "Lightning and Electricity of the Air," in *United States Weather Bureau, Bulletin No. 26* (Washington, 1899); W. J. Humphrey, in the *Monthly Weather Review*, vol. xlii (ib., 1914), where is given a list of important papers. See TERRESTRIAL ELECTRICITY.

LIGHTNING, ACCIDENTS FROM. Statistics have been kept for many years, both in Europe and America, showing the frequency of lightning strokes and the destruction done by them. Thus, according to the report of the Registrar-General for England, in 1871, 28 persons were killed; all but 5 were men and were chiefly laborers in the open air. In 1875, 17 were killed, and in 1877 only 10. Out of 103 deaths in five years (1852–56) there were 38 in July and 22 in August. According to Hellmann, in Schleswig-Holstein, during the decade 1874–83 the annual average of destructive lightning strokes per million of buildings was 163 for slate or metal roofs, 386 for wooden or thatched roofs, 6277 for chimneys, 8524 for windmills, and 306 for factories and steam chimneys. The danger to buildings in the open country is five times greater than in the cities. The number of deaths of human beings on the average of 15 years per million is 4 in Prussia and Baden and 3 in France and Sweden. The danger to buildings erected on chalk or marl is very small, but on clay or sand larger. Among forest trees the oak is most frequently struck and the beech least frequently. The records from 1833 to 1882, according to Von Bezold, show that there is a steady increase in the recorded number of strokes; possibly this may be explained by the increased care in collecting data. According to Prof. A. J. Henry, the records of the United States Weather Bureau show that during 1898 throughout the United States, excluding Alaska, the number of deaths by lightning was 367, and the number of injuries 491. The proportion of deaths to the population was greatest in the upper Missouri valley and portions of the Rocky Mountain region. The proportion of deaths by lightning to the total population was about 5 per million, which is higher than the average of most countries, owing to the large proportion of the agricultural population. Nine hundred and sixty-six barns or sheds, 735 dwellings, stores, or offices, 95 churches and schools, and 70 other buildings were struck and damaged, the approximate loss being about $1,500,000. Of the buildings struck 40 were provided with lightning rods, 855 were not; and in 952 cases this item was not recorded. Nine hundred and sixty-four head of cattle, 306 horses, 30 mules, 426 sheep, 116 hogs were killed, the total value of the stock being $48,257. The continuous barbed-wire fences that are used over the Western prairies are said to increase greatly the number of cattle killed by lightning, as these seek shelter in some corner of the field, and the lightning runs to them along the wire from very considerable distances. Consult A. J. Henry, "Loss of Life in the United States by Lightning," in *United States Weather Bureau, Bulletin No. 30* (Washington, 1901), and A. J. Jex-Blake, "Death by Electric Currents and by Lightning," in *British Medical Journal* (London, 1913).

LIGHTNING, PROTECTION FROM. When a flash of lightning strikes any object on the ground, it generally does some destruction, apparently owing to the fact that when the electric discharge passes through a poor conductor it heats that substance intensely. Thus, when a discharge passes through a living tree all the sap may be converted into vapor and all the passages filled with air or filled with sap burst open. When the flash strikes a shingle roof, it sets fire to the wood, or, striking the chimney of a house, it expands the air within the brickwork or evaporates the water in the cracks and thus breaks up the chimney by the explosion. When the discharge runs along the roots of a tree or an underground drain, it tears up the ground by the force of the explosive expansion of the water.

In general, perfect protection from a destructive flash can only be obtained by surrounding an object with a continuous metallic covering. This need not necessarily be a metal box, but may consist of a network of wire, or even a few metallic rods properly interconnected and the system thoroughly connected to the damp earth by being deeply embedded therein. For an ordinary building the rods should run vertically up and down each of the corners and horizontally along the ridge, the eaves, and every other edge or prominence on the roof; these are the exposed portions, and if they are well protected there is but slight chance that a flash will strike the building elsewhere. A partial protection is of course provided for by a single metallic wire or so-called lightning rod, especially if the upper end protrudes far above the building, but it is quite deceptive to suppose that any definite rule can be offered for calculating the so-called area of protection.

The conductors usually found on buildings have as their terminals sharp cones or prongs of copper which are gilded to protect the points and to prevent corrosion, while the conductors themselves are generally in the form of a metal rod, rope, or ribbon, and terminate either in plates buried in damp ground or by making connection with water or gas pipes. Modern authorities agree that the more points along the ridges and eaves of a roof, the greater the amount of safety, and these of course should point to the sky. A factory chimney or steeple in the neighborhood is apt to attract the lightning and in all cases should be protected by conductors, as it may be a source of danger to surrounding buildings and not a safeguard, as is commonly supposed. The lightning conductor should be of iron or copper, and if the latter material is employed, it is considered advantageous to use it in the form of bands or ribbons, but stranded copper-wire cable, about ⅜ of an inch in diameter, is more easily obtained in continuous lengths and meets practically every requirement. Iron, however, answers very well, being preferred by some authorities, and can be used in the shape of rod or tape. The lightning conductor should be of the same material and continuous throughout, joints being either avoided or constructed most carefully. In its course to the earth care should be taken not to have sharp bends, corners, or curves. An important consideration is the connection with the ground, and while it is possible to connect directly with water pipes, an independent ground is far better; running water, a deep well or boring, can be utilized with great advantage as a terminal for the conductor. A ton of charcoal or coke buried in the ground and a trench filled with the same material and leading to water also make a good ground.

In the United States there are few lightning flashes so intense that a good lightning rod, well earthed, will not provide an easy path for the lightning; and while such protection is not necessary for houses in the city built in close blocks with metallic roofs and cornices, yet for barns and dwellings in the country authorities unite in pronouncing good lightning conductors eminently desirable.

The Washington Monument at Washington, D. C., has furnished one of the best instances of the effectiveness of lightning conductors as a protective device. As it stands 555 feet in height in the centre of flat and well-watered ground, it should be a conspicuous mark for lightning. It is protected by means of a system of four heavy copper rods secured firmly along the edges of the pyramidal summit and joined together by numerous horizontal rods sunk into the horizontal seams of the marble masonry. At the extreme apex of the monument the four inclined main copper rods join the massive aluminium cap of the pyramid. The cap and the whole system of external copper rods are put into perfect electrical connection with the steel work constituting the stairway and elevator system of the monument. At intervals of about 5 feet the external system of copper rods is studded with copper points, numbering in all about 200. In the 30 years elapsing since this improved arrangement was introduced, the monument has not been injured in any way by lightning. Previously, when the aluminium cap alone constituted the receiving system for the thunderbolt, there was one lightning stroke which, while causing slight damage to the pyramid, nevertheless demonstrated the necessity for the better protection described above. Sir Oliver Lodge, the celebrated English authority on the subject of lightning conductors, who has within a few years advanced some novel ideas on this matter which have tended to change previous theories, says "Almost any conductor is probably better than none, but few or no conductors are absolute and complete safeguards." For further information, consult: Sir Oliver Lodge, *Lightning Conductors and Lightning Guards* (London, 1892); A. J. Henry, "Lightning and Lightning Conductors," in *Farmers' Bulletin No. 367* (Washington, 1909); L. J. Smith, "Protection of Farm Buildings from Lightning," in *Manitoba Agricultural College, Bulletin No. 4* (Winnipeg, 1911); E. W. Kellogg, "Use of Metal Conductors to Protect Buildings from Lightning," in *University of Missouri, Engineering Experiment Station, Bulletin*, vol. iii (Columbia, 1912); and United States Weather Bureau bulletins on lightning.

LIGHTNING ARRESTERS. Devices to protect electrical apparatus from damage by lightning. In the early days of telegraphy and telephony many accidents were caused by lightning striking the wires and running into the offices, often injuring the operator and destroying property. In order to obviate these difficulties an instrument was devised and called a lightning arrester. The original simple form is shown in Fig. 1. The three plates *A*, *B*, *C*, are mounted upon an insulating block. For example, the plate *A* is connected to the ground, *B* to one side of the telegraph or telephone in-

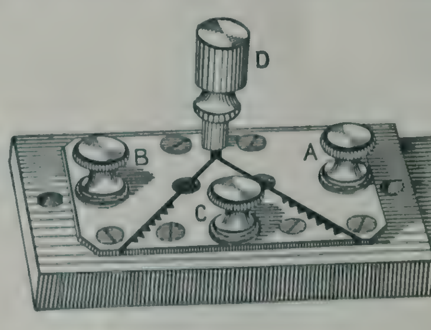

Fig. 1.

strument, and *C* to the line wire and to the other side of the instrument. In ordinary operation the currents from the line cannot go from *C* across to *A* without going through the instrument, but if the line is struck by lightning the latter comes to *C*, and by reason of its high pressure jumps from the jagged edges of *C* over to *A* and *B*, without going through the other instruments at all, on account of their high impedance (effective resistance). The arrester provides a crosscut, or short circuit, so that the lightning reaches the earth without going through the telegraph or telephone apparatus.

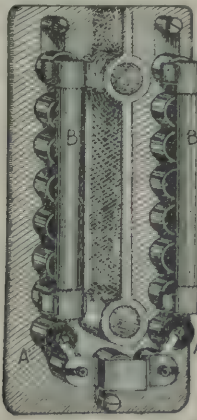

Fig. 2. LIGHTNING ARRESTERS.

Fig. 2 shows a simple form of arrester for electric-power circuits. *AA* are metallic cylinders separated from each other by air gaps about $\frac{1}{32}$ of an inch across; connected to the outer cylinders are high-resistance carbon sticks *BB*. As many of these units as are desired, depending upon the line pressure, can be connected in series between each wire of the transmission line and the ground. Lightning, striking the line, jumps across the gaps between the cylinders; any tendency to form a continuous arc is checked by the cooling effect of the mass of metal in the cylinders and the high resistance offered by the carbon sticks. Fig. 3 shows a simple arrester of a different type, used to protect a generator.

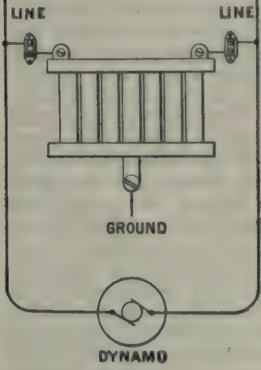

Fig. 3.

For the protection of transmission circuits carrying large quantities of energy at high voltage, special forms of lightning arresters are required. For this purpose two general types are in use, the horn-gap and the aluminium-cell arrester. The former is made of two metal rods curved somewhat in the shape of the horns of an animal and mounted on regular porcelain insulators. One of these is connected to the line to be protected from the lightning discharge, the other to the earth. At the lower extremity these horns are separated by a distance varying from about $\frac{1}{16}$ of an inch to as much as 10 inches, depending upon the operating voltage of the line, the latter distance being used at 110,000 volts. When a lightning discharge occurs, the current jumps to earth across the narrow space between the horns; but the tendency to form a destructive arc by the energy on the line is neutralized by the strong convection current in the air due to the development of heat at the gap and by the magnetic effect of the current, which together cause the discharge to rise rapidly from the point of its origin until the increasing space between the horns ruptures the arc.

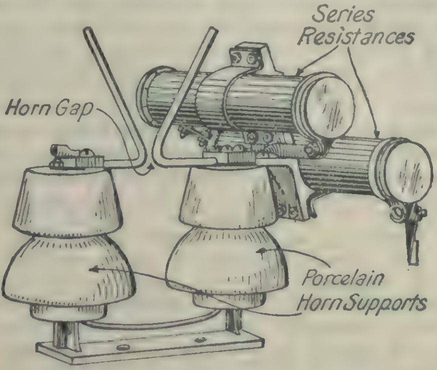

Fig. 4. HORN-GAP LIGHTNING ARRESTER.

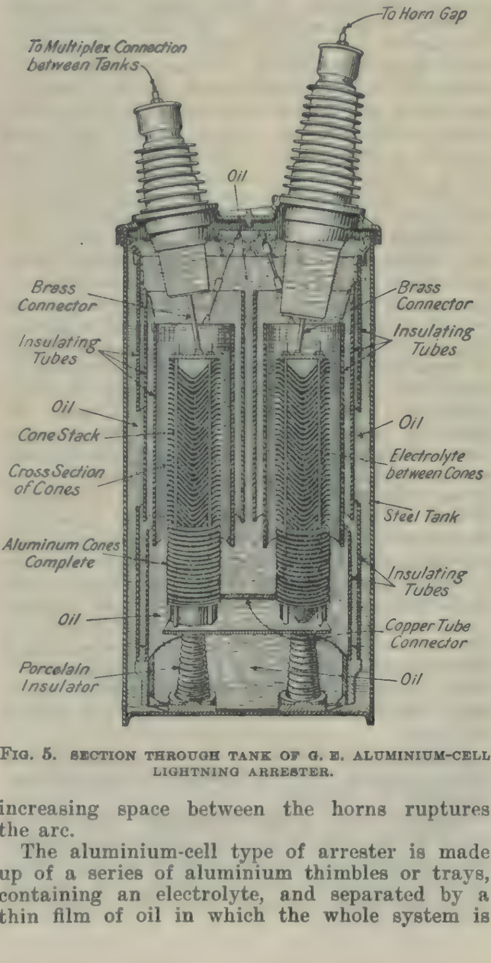

Fig. 5. SECTION THROUGH TANK OF G. E. ALUMINIUM-CELL LIGHTNING ARRESTER.

The aluminium-cell type of arrester is made up of a series of aluminium thimbles or trays, containing an electrolyte, and separated by a thin film of oil in which the whole system is immersed. One end of this system is grounded and the other connected to a modification of a horn-gap arrester, which in turn is connected to the line. A lightning discharge received by the line dissipates its energy in electrolytic action and by many small arcs across the air gaps between the trays. While no device has been so far put in use successfully to resist every lightning stroke, it is generally agreed by electrical engineers that the aluminium-cell type affords the maximum protection for high-voltage power circuits.

Bibliography. The most fertile field for information on modern practice is the files of the *Transactions of the American Institute of Electrical Engineers* (New York), and especially papers by R. D. Mershon, in vol. xxii (1903); N. J. Neal, in vol. xxiv (1904); H. C. Wirt, in vol. xxv (1906); N. Rowe, in vol. xxxvi (1907); E. E. Creighton, in vols. xxvi, xxvii, xxxiii (1907, 1908, 1914); R. P. Jackson, in vol. xxvi (1907); Steinmetz, in vol. xxvi (1907); Creighton and Shavor, in vol. xxxi (1912); papers in the *General Electric Review* (Schenectady, June, 1908, February, 1910).

LIGHTNING INJURIES. Individuals struck by lightning are not always instantly killed. When the stroke is fatal, the muscles become rigid, and the body of the victim either falls to the ground or, when supported, remains fixed in a rigid attitude. In such a case there may not be any visible sign of injury, but the heart may be ruptured or the internal organs damaged. On the other hand, the body may be mutilated, the bones shattered and stripped of their fleshy covering. Rigor mortis supervenes rapidly in fatal cases. Lightning is apt to follow a most fantastic course; the victim may be stripped of his clothing and remain uninjured, and metal substances may fuse and give rise to superficial burns. Nonfatal injuries are generally followed by sudden collapse, with unconsciousness. Recovery may be interrupted by drowsiness, fever, delirium, convulsions, and severe prostration. Other cases exhibit paralysis of one or more limbs, impairment of vision, or blindness, severe neuralgia, and other symptoms due to nervous shock. Many of these symptoms are recovered from only after the lapse of long periods of time. The slighter forms of lightning stroke may give rise to small subcutaneous hemorrhages, discolorations, and burns, varying in extent and degree. The growth of hair is sometimes arrested. A few cases have been reported in which the action of the current has been photographic, leaving pictures of neighboring objects upon the skin. Lightning burns heal very slowly. The treatment of nonfatal cases consists in the application of warmth to the surface of the body, artificial respiration, and the administration of stimulants hypodermically, or by mouth when this is possible. Lightning injuries are fatal in about 25 per cent of the cases.

LIGHT OF THE WORLD, The. 1. A poem by Sir Edwin Arnold (1891), treating of the life of Christ. 2. An oratorio by Sir Arthur Sullivan (1873). 3. A painting by Holman Hunt at Keble College, Oxford, showing the Saviour standing with a lantern before a tightly closed door.

LIGHTS, Ship's. Lanterns used on board ship. There are the *running lights* which are required by the Rules of the Road (q.v.), and which consist of *masthead lights* and *side lights.* In addition to these there are *signal lights* used in making signals (q.v.); *standing lights,* which are permanent lights on the lower decks or in the superstructure for lighting passageways and large compartments. In men-of-war it was formerly the custom to extinguish lights in the wardroom at 10 P.M., and the junior officers' quarters at 9, except when an extension of time was granted by the commanding officer. Since the introduction of electric incandescent lamps for lighting men-of-war and the separation of the wardroom and junior officers' messrooms from the staterooms, the rules have become less rigid. In passenger steamers lights are extinguished in certain saloons and other places at 11 or 12 o'clock.

LIGHTS, Use of, in Public Worship. A practice which prevailed in the Jewish (see Ex. xxv. 31–39) and some other ancient religions and was retained in the Christian Church —not merely for the obvious purpose of illumination, but as a token of joy and with a symbolic allusion to Christ as the "Light of the World." This particular symbolism finds its closest application in the paschal candle which is solemnly blessed on Holy Saturday. (See Easter.) There is some evidence pointing towards a repudiation by the early Church of lights in worship; but it is clear that by the fifth century the use of candles and lamps was an ordinary accompaniment of Christian worship and of the administration of the sacrament of baptism. It has been maintained uninterruptedly by the Roman Catholic and Eastern churches; at the Reformation it was abandoned by most Protestant bodies, though the Lutherans of Germany have very generally retained it, and there are a few instances of its survival in England before the practice again became general in the ritualistic movement of the nineteenth century. In numerous English instances the altar candles remained, but were not burned. In the Roman Catholic church their usage is strictly regulated; priests are forbidden to say mass without at least two lighted tapers; the material is limited to wax, which is used unbleached on Good Friday and in masses for the dead. Candles are solemnly blessed for public and private use on the Feast of the Purification, known by the English usage as Candlemas (q.v.). A small candle called *bugia* is placed upon the altar when a bishop celebrates mass; and in the case of the Pope seven candles are carried before him or held on each side of him in allusion to the seven golden candlesticks of Rev. i. 12. Pure olive oil is required for lamps. The red lamp burning before an altar usually, though not invariably, denotes the presence of the reserved Sacrament. Consult: Andreas Schmid, *Der christliche Altar und sein Schmuck* (Regensburg, 1871); Wolfgang Mühlbauer, *Geschichte und Bedeutung der Wachslichter bei den Kirchlichen Functionen* (Augsburg, 1874); Vernon Staley, *Studies in Ceremonial* (London, 1901).

LIGN ALOES, līn ăl′ōz. See Aloes Wood.

LIGNE, lē̆′ny’, Charles Joseph, Prince de (1735–1814). An Austrian soldier, diplomat, and author. He was born in Brussels and was descended from a wealthy and powerful Belgian family. In 1752 he entered the Austrian army, in which he served with distinction through the Seven Years’ War. During the reign of Joseph II he held high military and diplomatic positions, visiting every court on the Continent, and was particularly a favorite at the court of St. Petersburg. He was made a field marshal by Catherine II of Russia. He commanded the Austrian artillery at the siege of Belgrade in 1789. When the French conquered Belgium, he lost all his estates. He was one of the well-known figures of his time and corresponded with Rousseau, Voltaire, Frederick the Great, Wieland, Schlegel, and Goethe. Of his miscellaneous works in 34 volumes, which appeared in 1790–1811, Malte-Brun has given selections in two volumes (*Œuvres choisies*, 1809). His memoirs and letters have considerable historic value.

LIG′NIFICA′TION (from Lat. *lignum*, wood + *facere*, to make). A process in plants by which the more or less thickened cell wall becomes impregnated with lignin, a substance which makes the wall harder and more elastic. A lignified wall is permeable to moisture, but cannot absorb or retain much. Lignification occurs in the vessels and fibrous tissue, less often in parenchyma, and reaches its highest expression in the seed plants, where the lignified tissues constitute the wood. This tissue is also highly developed in the ferns and their allies, but in the mosses it is scanty or lacking altogether.

LIG′NIN. See Lignification.

LIG′NITE (from Lat. *lignum*, wood). A member of the coal series, which, although a mineral substance, is of vegetable origin and often shows a distinct fibrous or woody structure, clearly visible to the naked eye. The external form is sometimes well preserved, and lignitized tree trunks and pieces of lignitized wood are not uncommon in many clay and sand formations of recent geological age. Lignite has usually a dull lustre, conchoidal fracture, and brown streak. It may be brown or black in color and is often of open texture. It burns readily with a smoky flame and is inferior to the bituminous and higher grades of coal in its heating power. It grades into subbituminous coal, from which it is sometimes difficult to distinguish it. The latter, however, is usually black, has more lustre, and on account of its average lower moisture content does not disintegrate as readily. Lignite, on account of the high percentage of moisture which it contains, disintegrates rapidly on exposure to the air, and hence it cannot be stored for a long period or transported to a great distance without danger of its crumbling to powder. Lignite occurs in beds, its mode of occurrence being similar to that of the higher grades of coal; but the associated beds of rock are usually of a more or less unconsolidated nature and moreover show practically no disturbance. It is not found in formations older than the Mesozoic, and is especially abundant in those of Cretaceous and Tertiary age.

The following table gives the composition of some American lignites:

	PROXIMATE ANALYSIS				ULTIMATE ANALYSIS					CALORIFIC VALUE	
	Moisture	Volatile matter	Fixed carbon	Ash	Sulphur	Hydrogen	Carbon	Nitrogen	Oxygen	Calories	British thermal units
1	18.12	42.77	23.61	15.50	0.43	5.51	44.77	0.88	32.91	4,386	7,895
2	39.43	26.49	24.37	9.71	0.49	6.98	36.33	0.68	45.81	3,531	6,356
3	34.55	35.34	22.91	7.20	1.10	6.60	42.40	0.57	42.31	3,939	7,090
4	35.96	31.92	24.37	7.75	1.15	6.54	41.43	1.21	41.92	3,927	7,069
5	31.06	27.67	33.39	7.88	0.99	6.53	44.70	0.90	39.00	4,372	7,840
6	....	40.14	48.43	11.43	1.43	4.46	64.84	1.31	16.53	6,342	11,416

1, Cook Inlet, Alaska; 2, Ouachita Co., Ark.; 3, Dawson Co., Mont.; 4, McLean Co., N. Dak.; 5, Olsen, Tex.; 6, same as 5, moisture free.

Lignite may be used for fuel in the lump form as mined, provided it is consumed near the point of production. If this is not done, it is desirable, if not important, to use it in briquettes or in a gas producer. For the former it is pulverized and pressed into blocks or cakes, the lignite being either used alone or mixed with some form of binder, such as pitch. The quantity and kind of binder used is not the same in all cases. When the great lignite fields of the northwest are extensively developed, both of these methods of use will become important. Much of the material formerly called lignite is now classed as subbituminous coal.

Jet is a variety of lignite, of coal-black color, and so dense that it can be easily carved into small ornaments. Phillips states that it is a coniferous wood and was first found at Whitby and other localities in England, having been known since early British times. *Brown coal* is another name for lignite, which is chiefly used in Europe. *Bovey coal* is a local name used in Devonshire, where extensive beds occur. In the United States deposits of lignite are found chiefly in the Tertiary. Those worked occur in Arkansas, Texas, North Dakota, South Dakota, and Montana; but most of these are at the present time of comparatively little value, as there are better grades of coal available. A small area of no importance is situated in the Gulf States.

In western Canada much lignite is found in the Belly River series of the Cretaceous, underlying a large area in Alberta, while other deposits of Tertiary age are known in the Souris field of southern Saskatchewan.

LIG′NUM RHO′DIUM (Lat., Rhodian wood). The rose-scented wood of both root and stem of *Convolvulus scoparius* and *Convolvulus floridus*, exported from the Canary Islands. These are shrubs or small trees with linear leaves and bell-shaped flowers. The wood is usually marketed in strong, thick, and rather heavy cylindrical but knotty pieces covered with a cracked gray bark. Internally it is yellowish, and often reddish in the heart. It has an aromatic bitterish taste and when rubbed emits an agreeable roselike odor. Its strong-smelling essential oil (oil of lignum rhodium), obtained by distillation, is used for ointments, etc., and also very frequently to adulterate attar of roses. A similar article of commerce is obtained from *Amyris balsamifera*, a native of Jamaica, which yields an essential oil, closely resembling the former. The lignum rhodium of the Levant (*Liquidambar orientale*) is now rarely seen in commerce. From it, however, the name has been transferred to the other kinds.

LIG′NUM-VI′TÆ. A tropical tree. See Guaiacum.

LIGNY, lē′nyē′. A village in the Province of Namur, Belgium, 9 miles northeast of Charleroi, the scene of a battle between the French under Napoleon and a Prussian army under Blücher (Map: Belgium, C 4). After driving the Prussian vanguard from Charleroi on June 15, 1815, Napoleon dispatched Ney with 50,000 men to engage Wellington at Quatre-Bras, while the French right, numbering some 60,000, led by the Emperor and Grouchy, prepared to assail the Prussian army, which was drawn up more than 80,000 strong between the villages of Saint-Amand and Sombref, with its centre at Ligny. At three o'clock in the afternoon of the 16th the sound of heavy cannonading announced that fighting was going on at Quatre-Bras, 7 miles away. The Emperor immediately ordered an attack, and the Prussians at the first onset were driven from Ligny. They returned, however, in increased numbers and succeeded in recapturing the village, but only to lose it again. The battle was decided by a charge of the Guard and Cuirassiers through the centre of the Prussian army, which broke and fled in spite of Blücher's desperate endeavors to rally his troops. An unaccountable omission on the part of Napoleon to hurl Erlon's fresh corps on the rear of the discomfited Prussians saved the enemy from destruction. After the first moments of panic the retreat was admirably conducted by Gneisenau (q.v.), Blücher's chief of staff, who by falling back on Wavre made possible the subsequent opportune arrival of the Prussians on the field of Waterloo (q.v.). The Prussians lost about 12,000 men in dead and wounded, while the loss on the side of the French was 8000. Consult W. O'C. Morris, *The Campaign of 1815: Ligny, Quatre-Bras, Waterloo* (London, 1900).

LIGONIER, lĭg′ô-nēr′, John (or Jean Louis), Earl (1680–1770). A British soldier, born at Castres, France. He volunteered in Marlborough's army in 1702, purchased a captain's commission in the next year, and, beginning with the storming of Liége, he participated with distinction in nearly every important operation in the Low Countries until 1710. In 1712 he was appointed Governor of Fort St. Philip, Minorca, was adjutant general in 1718 of the expedition to Vigo, and in 1720–49 was colonel of the famous "Black Horse" regiment. Promoted to major general in 1739, he participated in the Rhine campaign of 1742–43, winning another promotion to lieutenant general in the latter year. In 1746, as commander of the British troops in the allied army in Austrian Netherlands, he participated in the battle of Roucoux, and in the next year as general of horse under the Duke of Cumberland he led a brilliant charge at the battle of Val. Although Ligonier defeated the designs of the enemy in this engagement, he was taken prisoner. After the Peace of Aix-la-Chapelle he returned to England, where he was elected to Parliament in 1748, was made commander in chief and Viscount in 1757, Baron in 1763, and Earl and field marshal in 1766.

LIGORIO, lē-gô′rĭ-ō, Pirro (1530–80). A Neapolitan architect and archæologist. He was employed by Paul IV (Pope, 1555–59), probably worked under Michelangelo, and constructed the Villa Pia at Rome. He built the Palazzo Lancellotti at Rome, and in 1564 he became associated with Vignola as engineer of St. Peter's Church. In 1568 he was engaged by Alfonso II d' Este at Ferrara, where he spent the remainder of his life. Thirty manuscript volumes of his *Le Antichità di Roma*, containing valuable drawings of ancient monuments, are to be found in the library at Turin, and others are in the Bibliothèque Nationale, Paris, at Naples, at the Vatican, at Windsor, and elsewhere.

LIGUESTE, lē′gĕst′, Pierre Laclède (1724–78). An American trader and the founder of St. Louis, Mo. He was born in France, emigrated to New Orleans later, obtained from the authorities there the exclusive right to trade in furs with the Indians on the Missouri, organized the Louisiana Fur Company, and in 1764 founded St. Louis (q.v.), where he continued to live until his death. His name is frequently written as Pierre Ligueste Laclède, but this is an incorrect order.

LIG′ULE (Lat. *ligula, lingula*, dim. of *lingua*, OLat. *dingua*, tongue; ultimately connected with Eng. *tongue*). In general, an outgrowth from the surface of a leaf or leaflike organ. In practice the name is applied in three groups of plants, the most conspicuous of which is the grass family. The leaves of grasses have two distinct regions, the spreading portion (blade) and that which envelops the stem (sheath). At the juncture of blade and sheath the ligule appears as a more or less conspicuous flaplike outgrowth. The two other groups are the little club mosses (*Selaginella*) and the quillworts (*Isoetes*), both of which belong to one of the great groups (Lycopodiales, q.v.) of the fern plants (Pteridophytes). In both of these cases there is an outgrowth from the surface of the leaf, which is particularly prominent in the very young stages of the leaf and may be regarded as an embryonic structure. In other cases of such outgrowths the term "ligule" is not applied, but the structure is essentially the same. For example, in some flowers of the pink family there is a two-toothed outgrowth from the surface of each petal, the five outgrowths encircling the throat of the flower and resembling a small 10-toothed crown, called in consequence a corona. A similar corona is conspicuous in the various species of *Narcissus*, as jonquils, daffodils, etc., often forming a striking feature of the flowers. The significance of ligular outgrowths in the plant economy is quite obscure. In the case of foliage leaves, as grasses, little club mosses, and quillworts, they seem to be structures that are of service only in the embryonic stages of the leaf, disappearing entirely or remaining only as rudiments when the blade is mature. In flowers, as in pinks and species of *Narcissus*, they add to the floral display and are doubtless of service in connection with insect pollination.

LIGUORI, lé-gwō′ré, ALFONSO MARIA DI, SAINT (1696–1787). A Roman Catholic ecclesiastic and theologian, founder of the Redemptorist (q.v.) Order. He was born of a noble family at Marianella, near Naples, and at first studied law, taking his doctor's degree at the age of 16 and beginning to practice at 20. Six years later he abandoned the profession for the purpose of devoting himself to a religious life. He was ordained priest in 1726 and undertook with great zeal the duties of his new calling. Under the influence of Thomas Falcoja, Bishop of Castellamare, he decided to found a new congregation for missionary effort; and in 1732, at Scala, near Amalfi, he organized the Congregation of the Most Holy Redeemer, which Pope Benedict XIV approved in 1749, appointing the founder general for life. In 1762 he was appointed Bishop of Sant' Agata de' Goti in the Kingdom of Naples. After instituting many reforms and suffering from a disabling illness, he resigned his see in 1775, after which he returned to his order and continued to live in simple austerity until his death, at Nocera de' Pagani, in 1787. He was beatified in 1816, canonized in 1839, and solemnly declared a doctor of the Church in 1871. The special importance of his teaching is in the department of moral theology. Under the name of Probabiliorism, a modification of the earlier so-called Probabilism, it has been very widely followed in the direction of consciences in the Roman Catholic church. His most important work is his *Theologia Moralis* (1753), which grew out of an edition of Busembaum's earlier treatise published by him in 1748 (Eng. trans., abridged, 7th ed., 2 vols., New York, 1890). The best edition is by Gaudé (Rome, 1905). His complete works have been frequently published, recently at Turin (1877 et seq.). Part of a projected English version has been published (London, 1854–68). A complete translation into Latin was made by P. Walter (New York, 1903).

Bibliography. Lives by Rispoli (Naples, 1837) and A. Capecelatro (Siena, 1893; Fr. trans., Paris, 1895), in Italian; by Clément Villecourt (Tournay, 1864), Henri Saintrain (ib., 1879), and Berthe (2 vols., Paris, 1900; Eng. trans., St. Louis, 1906), in French; and by C. Dilgskron (Regensburg, 1887), in German. An English translation of the life by his disciple Tannoja (1798–1802), edited by W. Faber, appeared in London (1848–49). For a discussion of his moral theology, consult: C. B. Gousset, *Justification de la théologie morale d'Alphonse de Liguori* (Besançon, 1832); Frederick Meyrick, *The Moral and Devotional Theology of the Church of Rome according to the Authoritative Teaching of Saint Alfonso di Liguori* (London, 1856); Wittmann, *Saint Alphonse et le pur probabilisme* (Gien, 1891); Franz Meffert, *Der heilige Alfons von Liguore der Kirchenlehrer und Apologet des XVIII. Jahrhunderts* (Mainz, 1901); J. Magnier, "Bibliotheca Alphonsiana," in *Irish Ecclesiastical Record*, vol. xv (4th series, Dublin, 1904); Peter Junglas, *Der rechtsgeschichtliche Hintergrund für Leguoris Lehre vom Gerichtseide* (Kempton, 1913).

LIGURES, lĭg′ů-rēz. See LIGURIA; LIGURIAN.

LIGURES BÆBIANI. See LIGURIA.

LIGU′RIA. In ancient geography, a region in north Italy (Map: Italy, B 2). As defined in the time of Augustus, it embraced the territory from the Ligurian Sea (Gulf of Genoa), across the Maritime Alps, to the Po in the north, and from the Varus in the west to the Macra in the east. At a very early period the Ligures possessed a larger territory, extending far into Gaul, on the west side of the Rhone, and perhaps even into Spain; in Italy their land spread once as far south as Pisa and Arretium. The Ligurians (Lat. *Ligures*) were fine soldiers and sailors. They were subjugated by the Romans in the second century B.C. In 180 B.C. the consuls Bæbius and Cornelius transferred 47,000 Ligurians from the territory about Luna to two places in Samnium; these settlements were known as Ligures Bæbiani and Ligures Corneliani. The site of the former has been found, 15 miles north of Beneventura. There a large bronze tablet was found, giving important information concerning a foundation of Trajan (q.v.), whose purpose was the support of poor children. Augustus made Liguria, a district more extensive than modern Liguria, the ninth region of Italy. Genua (now Genoa) was the most important town of the district. (See also POLLENTIA.) Modern Liguria includes two provinces, Genoa and Porto Maurizio; these belonged for a time to the Republic of Genoa (q.v.). Ancient Liguria produced timber, sheep, mules, ponies, and cattle; modern Liguria produces maize, wheat, lemons, oranges, wine, fruits, and potatoes. The coast district of Liguria is known now as the Riviera (q.v.). (See LIGURIAN.) Consult the article "Ligurer," in Friedrich Lübker, *Reallexikon des klassischen Altertums*, vol. ii (8th ed., Leipzig, 1914).

LIGU′RIAN. The name now applied to the tall, dark, long-headed people about the Gulf of Genoa, Italy, and southward. Formerly the term was given under a misapprehension to the broad-headed type of middle Europe. It is now believed by some scholars that the entire Italian peninsula was peopled by a primitive long-headed Ligurian type, underlying the modern one. The purest representatives of the ancient Ligurians are the tall, dark, and exceedingly dolichocephalic population of the district about Lucca. It is claimed that they preceded the Romans in Italy. The evidence of their inscriptions, particularly of the place names found in those inscriptions, would seem to show that the Ligurians were Indo-Europeans.

Husband, "Race Mixture in Early Rome," in *Transactions of the American Philological Association*, vol. xl (Boston, 1909); id., "Kelts and Ligurians," in *Classical Philology*, vol. vi (Chicago, 1911); the article "Liguria," in Lübker, *Reallexikon des klassischen Altertums*, vol. ii (8th ed., Leipzig, 1914). See ITALY, *Ethnology;* LIGURIA; MEDITERRANEAN RACE.

LIGURIAN REPUBLIC. The name given to the Republic of Genoa in 1797, when it was obliged by Napoleon Bonaparte to exchange its aristocratic for a democratic constitution. It was ruled by a directory till 1802, when a doge was made the chief executive. In 1805 the Republic was incorporated in the French Empire. See GENOA.

LIGURIAN SAGE. A name given to the poet Aulus Persius Flaccus.

LI HUNG CHANG, lē hụng chäng (1823–1901). A Chinese statesman, born in Luchow, Ngan-hwei Province, Feb. 16, 1823. He was well educated and passed through the various grades of scholarship, receiving the highest degree (Tsin-shi) in 1847. In 1849 he entered the Hanlin College. As early as 1853 he distinguished himself in the field against the Taipings at the head of militia he himself raised. Passing through several minor offices, he became in 1864 Governor of the Kiang Provinces, in which capacity he was intrusted with the task of putting down the Taiping rebels who had continued to hold their own. With the assistance of the "Ever-Victorious Army" under Charles George Gordon (q.v.) Li Hung Chang was successful in suppressing the rebellion. When Nanking was captured, Gordon promised that the lives of the rebel leaders should be spared; but they were all killed by Li's orders—a treacherous act, which so angered Gordon that he resigned his command. Li now became successively commander of the Chinese Imperial forces, an earl, head of the naval administration, and Viceroy of the capital Province of Chi-li. This last appointment placed him practically next the throne, and he held it for the exceptional period of 24 years, from 1870 to 1895. During the entire period the foreign policy of China was under his control. Without becoming a partisan of the Western civilization, he recognized the necessity of reorganizing the fighting forces of China on a modern basis, in order to meet the threatening encroachments of the European Powers and the rising influence of Japan, whose interests in Korea were coming into conflict with those of the Chinese. Under Li's supervision the army and the navy were greatly strengthened. The war with Japan found him in a position of great responsibility. He had been instrumental in bringing on the war, and he had to bear the brunt of the defeat which followed, although the inefficiency of the Chinese forces was largely due to the way in which his plans for military and naval improvement had been hampered by Chinese court methods. It was equally a part of these methods that he should be made a scapegoat by the Emperor, and accordingly before the close of the war he was removed from office, deprived of the insignia of his rank, and sent into retirement. He was, however, recalled and invested with full powers to negotiate a peace with Japan after the fall of Wei-hai-wei. He was received in that country with respect and obtained terms which, hard as they were, were probably better than could have been obtained by any other person under the circumstances. In 1896 he represented China at the coronation of Emperor Nicholas II of Russia and then made a tour of the world, passing through Germany, France, England, and the United States, and was received everywhere with high honors. Upon his return to China he became the virtual head of the Tsung-li Yamen, or Foreign Office. He returned to the governership of the Kiang Provinces in 1900, but was soon recalled to the governorship of Chi-li and his former extensive powers, because he was the only man who could be relied upon to meet the emergency in the foreign relations of the Empire produced by the Boxer outbreak. His last public task was the settlement with the European Powers and the United States of the issues raised by that trouble. He died Nov. 7, 1901. Li Hung Chang was able, crafty, and, according to European morals as well as the best teachings of the Chinese moral code, unscrupulous. He accumulated a colossal fortune in the public service. He was not a friend to the foreigner, but he believed in the value of the material civilization of the West and wished China to profit by its lesson and strengthen herself thereby. It was commonly believed that Li was not incorruptible, and it was asserted that he had accepted retainers from Russia. He certainly sought to maintain a good understanding with that Empire, though this may well have been only what he regarded as a necessary policy under the circumstances. In internal policies he was generally identified with the party of the Dowager Empress, though he was too shrewd to go all lengths with her radical advisers. Li Hung Chang could not, however, have been the statesman he unquestionably was if he had not preserved a certain rugged integrity of purpose. While he sought his own advantage, he served his country sincerely and was one of her few statesmen of commanding ability. He was a man of powerful physique and great capacity for work. Consult: R. K. Douglas, *Li Hung Chang* (London, 1895); R. E. Lewis, "The Machiavelli of Chinese Diplomacy," in the *Forum*, vol. xxxi (New York, 1901); D. C. Boulger, "Li Hung Chang: Statesman or Impostor," in *Fortnightly Review*, vol. lxxvi (London, 1901); W. F. Mannix (ed.), *Memoirs of Li Hung-Chang* (Boston, 1913). See CHINA.

LI′LAC (Sp. *lilac*, from Ar. *līlāk*, lilac, from Pers. *lilaj, lilanj, lilang*, indigo plant, from *nīlah*, indigo plant, Skt. *nīla*, dark blue), *Syringa.* A genus of shrubs and small trees of the family Oleaceæ. The common lilac (*Syringa vulgaris*), a native of the north of Persia, is one of the most common ornamental shrubs cultivated in Europe and North America. It was first brought to Vienna during the latter part of the sixteenth century by Busbecq, the Ambassador of Ferdinand I, who also introduced the tulip into European gardens. There are many fine single and double flowered varieties. The blossoms, which appear in May in large terminal clusters, are bluish, purple, or white, and very fragrant. The plant grows from 6 to 15 feet high and is well adapted for grouping in landscape gardening. The wood is fine-grained and is used for inlaying, turning, and making small articles. The lilac succeeds almost anywhere, but does best upon a rich deep loam. It is usually propa-

gated by means of suckers, which often appear too freely, or by cuttings of mature or green wood. Choice varieties, of which there are many, are often grafted on privet and common lilac stocks. Flowers may be obtained throughout the year by artificial greenhouse methods. See Plate of California Shrubs.

LIL'BURNE, John (1614–57). An English agitator and pamphleteer. He was born at Greenwich and was educated at Newcastle and Auckland. He was apprenticed to the wholesale cloth trade, but, imbibing opinions in opposition to the English church, at the age of 18 he went to Holland to procure the printing of a pamphlet against the bishops. This he sought to circulate secretly, but was exposed to the authorities, tried in the court of the Star Chamber, condemned in February, 1637, to receive 500 lashes, to be pilloried and confined in prison, fined £500, and required to give security for good behavior. His courage before the judge and during his punishment gained him the sobriquet of Freeborn John. Given his liberty in 1640, he placed himself at the head of the "levelers" (q.v.) and demanded that Lord Stratford should be arraigned. He was again arrested and taken before the House of Lords; but such was the pressure of public opinion in his favor that Parliament released him and subsequently declared his punishment to have been illegal, barbarous, and tyrannical, and recompensed him for his imprisonment and injuries by the payment of £3000. He joined the army of the Parliament against Charles I, became lieutenant colonel, was taken prisoner at Brentford, and would have been hanged had not the Parliament's general, the Duke of Essex, threatened to hang Royalist prisoners in retaliation. He soon became dissatisfied with the Presbyterian leaders and published charges and denunciations even against Cromwell. The latter procured his trial before a commission, by whom he was acquitted. Emboldened by this, he began a violent agitation against Cromwell, read in public a pamphlet entitled *England's New Chains*, and in consequence was committed to the Tower. Thence he poured out political pamphlets which gave him great popularity with the people. He was again brought to trial, but the pressure of popular opinion in his favor determined his acquittal. But Cromwell soon after secured his condemnation and banishment for a vicious attack on Haselrig. During his exile he resided in Brussels and Amsterdam and intrigued with Royalist exiles for the restoration of the monarchy. After the dissolution of the Long Parliament he returned to England without permission and was immediately arrested and tried. Although acquitted of any crime meriting death, his freedom was denied him for "the peace of the nation" until 1656, when, having espoused the doctrines of the Friends, or Quakers, he was released. He died at Eltham. The title of his earliest biography is *The Self-Afflicter Described* (London, 1657). Consult S. R. Gardiner, *History of the Great Civil War* (London, 1901), and, for a complete bibliography of his pamphlets, *Notes and Queries* (ib., 1888).

LIL'IA'CEÆ (Neo-Lat. nom. pl., from Lat. *lilium*, from Gk. λείριον, *leirion*, lily; connected with λειρός, *leiros*, pale), The Lily Family. A large family of the monocotyledons, including approximately 2500 species, or about one-eighth of the monocotyledons. This family may be regarded as representing the typical monocotyledons. Its members can be recognized as having hypogynous and showy flowers, with three sepals, three petals, six stamens, and three carpels, which are syncarpous, ripening to form a capsule, but in some groups forming a berry. The range of variation in the family may be indicated by the fact that at least 13 tribes are represented, but they are distinguished from one another by various simple combinations of characters. Many of the so-called lilies of cultivation are not members of this family, but belong either with the *Iris* or *Amaryllis*. These false lilies may be recognized at once by the fact that their flowers are epigynous. Among the useful plants of the family are *Asparagus* and *Allium* (onion, leek, garlic, etc.). Among the well-known garden flowers are *Convallaria* (lily of the valley), *Lilium* (lilies of various kinds), *Tulipa* (tulip), *Hyacinthus* (hyacinth), and *Hemerocallis* (day lily). The conspicuous North American genera are as follows: *Veratrum* (hellebore), *Uvularia* (bellwort), *Allium* (onion), *Lilium* (lily), *Erythronium* (dog's-tooth violet), *Yucca* (Spanish bayonet), *Smilacina* (false Solomon's seal), *Polygonatum* (Solomon's seal), *Trillium* (wake-robin), and *Smilax* (greenbrier).

LILIBEO, lē'lê-bā'ō. See Cape Boeo.

LILIENCRON, lē'lĭ-*e*n-krōn, Detlev (Friedrich), Baron von (1844–1909). A German poet and novelist, one of the best modern lyrists and a leader in revolutionary literary circles. He was born in Kiel, entered the Prussian army, served in the campaigns of 1866 and of 1870–71, and was severely wounded in each. He left the army on account of debts. After trying to recoup his fortune in America—his mother was born in Philadelphia—he was in the employ of the German government until 1887, when he devoted himself entirely to literature. He married three times. One of the oldest of the "Young German" authors, Liliencron was also one of the most influential; he was a member of the Berlin Freie litterarische Gesellschaft and one of the founders of the Munich Gesellschaft für modernes Leben. Nearly all of the members of the new school in Germany became attached to him by personal or literary ties. His lyrics are better than his novels, among which mention should be made of the popular *Breide Hummelsbüttel* (1886; 2d ed., 1900), *Der Mäcen* (1890; 3d ed., 1900), and the *Kriegsnovellen* (1896; 4th ed., 1902); and much better than his dramas, such as *Der Trifels und Palermo* (1886) and *Pokahuntas* (1905). In the lyrics and ballads there is enough marching rhythm to win him the title of "soldier poet," and there is an especial felicity in his backgrounds of Schleswig scenery and in his realistic and dramatic narrative; but, on the other hand, there is some affectation of manner. His themes are frequently erotic. His chief poetic titles are *Adjutantenritte* (1883); *Gedichte* (1889); *Neue Gedichte* (1893); *Poggfred* (1896 et seq.), a fantastic epic; *Nebel und Sonne* (1900; 4th ed., 1904); *Bunte Beute* (1903; 5th ed., 1905). His works appeared at Berlin in 14 volumes in 1904–05.

LILIENCRON, Rochus, Baron von (1820–1912). A German author, born at Plön, Holstein. He studied theology, jurisprudence, and philology at Kiel, Berlin, and Copenhagen. In 1847 he became privatdocent at Bonn. After holding various government positions he became in 1850 professor at Kiel and in 1852 was appointed to the chair of German language and literature at the University of Jena. While there he published, with W. Stade, *Lieder und Sprüche aus der letzten Zeit des Minnesangs* (1854). In 1858, under the direction of the Historical Commission of Munich, he began the collection of folk songs, which culminated in his *Historische Volkslieder der Deutschen vom 13.–16. Jahrhundert* (4 vols., 1865–69). The same commission also charged him with the editing of the *Allgemeine deutsche Biographie.* In 1869 he was made a foreign member in ordinary of the Bavarian Academy of Sciences and settled in Munich. In 1879 he removed to Schleswig. From 1892 to 1900 he was editor of *Denkmäler der deutschen Tonkunst.* He published numerous valuable articles in various musical and philological journals.

LILIENTHAL, lē′lĭ-*e*n-täl′, Otto (1848–96). A German aëronautical engineer, born at Anklam, Prussia. He was educated at the trade school in Berlin, then worked for Schwartzkopff and Hoppe in that city, and in 1880 established a factory in which he manufactured several articles of his own invention. Becoming interested in aëronautics, he attempted to work out the method of successful air flying by men by exact imitation of the flight of birds, and in one of his experiments he was killed. He is author of *Der Vogelflug als Grundlage der Fliegekunst* (1889), which was translated by A. W. Isenthal as *Birdflight as the Basis of Aviation* (1911), and of *Die Flugapparate: allgemeine Gesichtspunkte bei deren Herstellung und Anwendung* (1894).

LILITH, lĭl′ĭth *or* lī′lĭth (Heb., night monster, night fairy; connected probably with *layil,* Ar. *lail,* night). A female demon mentioned in the Old Testament. The word occurs in Isaiah (xxxiv. 14) and is translated in the English versions by screech owl or night monster; it is, however, to be regarded strictly as a proper name, probably Babylonian in its origin, since in the incantation rituals of the Babylonians the demon *Lilu* and a female consort *Lilitu* occur and are pictured as sprites that plague men particularly during the night. The Jewish rabbinical writings contain many fables about Lilith. She is there regarded as a beautiful woman, the first wife of Adam; she became a demon, however, and Eve was given to Adam in her place. Lilith was believed especially hostile to children, and amulets were worn to ward off her pernicious influence.

LILIUOKALANI, lē′lē-o͞o′ō-kȧ-lä′nē, Lydia Kamekeha (1838–1917). For a time Queen of the Hawaiian Islands, sister of King Kalakaua, whom she succeeded in 1891. She married John O. Dominis, a native of Boston, who became Governor of Oahu, and through his influence she was at first favorably inclined to American interests. She was appointed Regent during King Kalakaua's last visit to the United States and at his death succeeded him on the throne. Unfortunately her husband died soon afterward, and the Queen allowed herself to be influenced by unworthy counselors. She secured the passage of bills authorizing the importation of opium and the establishment of the Louisiana lottery and endeavored to substitute a reactionary constitution for the liberal one of 1887. This last measure aroused the white population of the islands, who would have been disfranchised under the proposed constitution, and on Jan. 30, 1893, they deposed her and set up a provisional government which soon became a Republic, with Sanford B. Dole (q.v.) at its head. The new government immediately sought to secure the annexation of the islands to the United States; but President Cleveland opposed this policy and, on the ground that United States forces had been used to dethrone the Queen, demanded that the republican government restore her to power. This Dole and his advisers refused to do, and after a show of force President Cleveland was compelled to acquiesce. The ex-Queen visited the United States in order to plead her cause and then retired to her private estate in Honolulu. In 1908 she made a claim on the United States government for $450,000, but the Court of Claims decided against her two years later. She was granted a pension by Congress of about $40,000. In 1914 she visited Hawaii after a long residence in San Francisco and expressed great pleasure at the rapid strides in civilization made by her former subjects under American rule. See Hawaiian Islands.

LILJEFORS, lĭl′yĕ-fôrs′, **Bruno (Andreas)** (1860–). A distinguished Swedish painter of animals and landscapes. He was born at Upsala and studied at the Academy of Arts in Stockholm and for a short time under Deiker in Düsseldorf. After traveling in Germany, Italy, and France, and absorbing, without imitating, all modern tendencies, including the Japanese conception of nature and movement, he returned to Sweden and developed a very original art, both in choice and treatment of subject. With an intimate knowledge of natural history and the keen observation of the hunter and explorer, he painted animals and birds in the solitude of the forest or the sea. His earlier paintings are characterized by minute detail and marvelous vivacity of movement. After his removal to the Stockholm Archipelago in 1890 his work increased in boldness of treatment, with a rendering of atmospheric and light effects often unique. Many of his finest paintings, including "Sunrise," "Eider Ducks," "Hare in the Snow," "Snipe," "The Panther's Skin," and "Swans," are in the Thiel Gallery in Stockholm. Among those in the National Gallery, Stockholm, are "Common Curlew" and "A Fox Family." Four excellent examples of his art—"Foxes," "The Hunter," "Fox Hunting," and "Birds in the Snow"—were exhibited at the Scandinavian Art Exhibition in New York in 1912. Liljefors received gold medals at Munich and Berlin. Consult Tor Hedberg, *Bruno Liljefors* (Stockholm, 1902).

LILLE, lēl (Flem. *Ryssel*). The capital of the Department of Nord, France, a first-class fortress and one of the principal manufacturing centres of the Republic (Map: France, N., H 2). It is situated in a level district on the navigable Deule, about 7 miles from the Belgian frontier and 154 miles by rail north-northeast of Paris. Its fortifications, rebuilt almost entirely during the nineteenth century, consist of an extensive enceinte with numerous forts, and the pentagonal citadel at the northwestern end of the town, designed by Vauban. Lille is practically a modern town, the portion south of the Boulevard de la Liberté (formerly the southern limit of the fortifications and now the centre of the town) having been annexed at the reconstruction of the fortifications in 1858–66. It is well laid out and has fine squares, avenues, and boulevards, which are traversed by a number of street railways. There are few ancient buildings of note; the principal churches are those of St. Catharine (built during the fifteenth, sixteenth, and eighteenth centuries, and containing a painting by Rubens, "The Martyrdom of St. Catharine"), St. Madeleine (seventeenth century), St. Andrew (eighteenth century, with paintings by Flemish masters), and St. Maurice. Of these, the only one of considerable architectural importance is St. Maurice. It is in the late Gothic style, the oldest parts dating from the fifteenth century, and was restored in 1872. The church of Notre Dame de la Treille, a grand edifice in the style of the thirteenth century, was begun in 1855. The secular edifices include the Bourse, dating from 1652, with a court surrounded by arcades and containing a bronze statue of Napoleon I by Lemaire; the modern town hall (1847–59), with the communal library and a museum of engravings; and the prefectural building. The Palais des Beaux-Arts, opened in 1892, has one of the largest collections of paintings to be found in a provincial town in France, containing many canvases by Flemish, French, and Italian masters; a collection of about 1500 drawings, chiefly by the Italian masters, collected by the painter Vicar, a native of Lille; collections of antiquities, sculptures, medals, and coins, and the noted ethnographical collection of Moillet. Lille is well provided with educational institutions. The chief of them are the State University, founded in 1808, with four faculties, an attendance of 1828 in 1912–13, and a library of 407,000 volumes; a Catholic university, with five faculties and an attendance of 550; a technical high school; a lycée, an art school, a conservatory of music, a theatre, botanical and zoölogical gardens, and several scientific associations. The communal library contains 100,000 volumes, over 1430 manuscripts, including about 200 incunabula. Lille has long been noted for its industrial activity, especially in the textile industry. It is full of manufacturing establishments for the production of linen, velvet, ribbons, knit ware, etc., which form its chief products. There are also manufactured machinery, various instruments, chemicals, soap, sugar, trimmed lumber, tobacco, oil, etc. The trade in local manufactures, agricultural and colonial products, is extensive. Lille is the seat of a number of foreign consular agents. The population of the city was largely augmented by the annexation of the suburbs during the second half of the nineteenth century. From 75,000 in 1856 it rose to 158,117 in 1872, 201,211 in 1891, and 216,276 in 1896; it fell to 210,696 in 1901, and 205,602 in 1906, but rose to 217,807 in 1911. These figures are for the commune.

Lille grew up around the castle of Buc in the eleventh century. It was fortified by Count Baldwin IV of Flanders in 1030 and by the twelfth century had become one of the chief commercial cities of Flanders and the centre of an extensive linen industry. It suffered much from the struggles between the counts of Flanders and the kings of France and passed to the latter at the beginning of the fourteenth century. Lille regained its prosperity with its passing to the dukes of Burgundy in 1369. It subsequently came into the possession of Austria and then of Spain and was conquered by Louis XIV in 1667. It was gallantly defended by Boufflers against Prince Eugene in 1708, but was finally reduced. Another notable event in its annals is its heroic resistance during the siege by the Austrians in 1792. Again, in the European struggle which broke out in 1914, Lille suffered from the rigors of war. For months it was the centre of furious battles between the German and allied English, French, and Belgian armies. It was occupied first by one and then by the other. Several of the buildings of the city were destroyed by the heavy German artillery. It was also forced to pay a large war tribute while in German hands. See WAR IN EUROPE. Consult Edouard van Hende, *Histoire de Lille* (Lille, 1874).

LILLEBONNE, lĕl'bŏn'. An ancient town in the Department of Seine-Inférieure, France, situated 20 miles east of Havre in the valley of the Bolbec (Map: France, N., F 3). It has a ruined castle built by William the Conqueror, an ancient donjon, and numerous Roman remains, including the ruins of a theatre. Cotton goods are manufactured. Lillebonne, the ancient *Juliobona*, capital of the Caletes, was destroyed by Julius Cæsar and rebuilt by Augustus. It was of considerable importance under the Roman rule. Pop., 1901, 6425; 1911, 4843.

LIL'LIBULE'RO. An Irish ballad with the refrain: *Lillibulero bullen a la.* It was composed in or about 1687 as a satire on the administration of Tyrconnel as Lord Deputy in Ireland, attained great popularity, and was a source of much strength to the anti-Jacobites during the English revolution of 1688 and the early years of the reign of William and Mary. The ballad is attributed to Lord Wharton and the musical setting to Henry Purcell, but there is much uncertainty as to Purcell's part in it.

LIL'LIE, FRANK RATTRAY (1870–). An American zoölogist. Born at Toronto, Canada, he graduated from the university of that city in 1891, and then studied at Clark University (1891–92) and at the University of Chicago (Ph.D., 1894). Afterward he was instructor in zoölogy at the University of Michigan (1894–99); professor of biology at Vassar College (1899–1900); and at Chicago assistant professor and associate professor of zoölogy and embryology from 1900 to 1907, professor after 1907, chairman of the department of zoölogy after 1911, and associate curator of the Zoölogical Museum after 1902. In addition he served as head of the department of embryology (1893–1907), assistant director (1900–08), and director after 1908 of the Marine Biological Laboratory, Woods Hole, Mass. He became managing editor of the *Biological Bulletin* in 1902, and associate editor of the *Journal of Experimental Zoölogy.*

LILLIPUT, lĭl'ĭ-pŭt. The name of a fabulous kingdom described by Jonathan Swift (q.v.) in *Gulliver's Travels* (1726). The Lilliputians were no bigger than a man's finger. The term Lilliputian means a tiny dwarf, or almost anything on a very small scale.

LIL'LO, GEORGE (1693–1739). An English dramatist. A jeweler by trade, he made dramatic composition his avocation. With a vigorous style and a moral tendency in advance of his time, he was the representative of the domestic manners and tastes of the middle classes. His plays *Silvia* and *The London Merchant, or The History of George Barnwell*, appeared in 1730 and 1731. The latter was extremely popular, and, if not intrinsically of high value, is important for its influence—an influence which can be directly traced—upon the sentimental drama both in France and Germany, reaching the latter country through Lessing. His other works are: *The Christian Hero* (1735); *Fatal Curiosity* (1736); *Marina* (1738), an adaptation of Shakespeare's *Pericles; Elmerick* (1740); and a version, completed by John Hoadley, of *Arden of Feversham* (1759). Consult Leopold Hoffman, *George Lillo* (Marburg, 1888), and *Lillo's Dramatic Works with Memoirs of the Author by Thomas Davies* (reprint, London, 1910).

LILLOOET, lĭl′o͞o-ĕt (wild onion). One of the four principal Salishan tribes in the interior of British Columbia. See SALISHAN STOCK.

LIL′LY, JOHN. An English writer of the sixteenth century, author of *Euphues*. See LYLY.

LILLY, WILLIAM. See LILY, WILLIAM.

LILLY, WILLIAM (1602–81). An English astrologer, born in Leicestershire. As a young man he was employed as bookkeeper by a London merchant, later took up the study of astrology, particularly the *Ars Notoria* of Cornelius Agrippa, and soon became widely known as a caster of nativities and predicter of future events. From 1644 till his death he annually issued his *Merlinus Anglicus Junior*, an almanac, containing vaticinations to which considerable importance was attached by many. His *Monarchy or No Monarchy* (1651) included, among other hieroglyphical engravings, two which he subsequently asserted predicted the plague and fire of 1666. In the Civil War he was sent to the Parliamentary camp at Colchester, to encourage the troops. After the Restoration he was for some time imprisoned, on the supposition that he was acquainted with the secrets of the Republicans. He was satirized in *Hudibras*. His chief work was the *Christian Astrology* (1647). An *Autobiography* appeared posthumously in 1715. His books and pamphlets were too numerous to chronicle here. His most notable work outside of astrology was *True History of King James I and King Charles I* (1651).

LILY (AS. *lilie, lilige*, from Lat. *lilium*, from Gk. *λείριον, leirion*, lily), *Lilium*. A large genus of bulbous plants of the family Liliaceæ, containing many species prized for their size and the beauty of their flowers. The bulb is scaly, the stem herbaceous and simple, often several feet tall; the flowers, borne at or near the summit, bell-shaped, the segments of the perianth often reflexed. The white lily (*Lilium candidum*), a native of southern Europe and the Levant, long cultivated in gardens, has large, erect, pure white flowers. The orange lily (*Lilium bulbiferum*), a native of the south of Europe, with large, erect, orange-colored flowers, is a well-known and very showy ornament in flower gardens. The Turk's-cap lily (*Lilium martagon*), a native of the south of Europe, and allied species with verticillate leaves and drooping flowers, are also common in gardens. The tiger lily (*Lilium tigrinum*), a native of China, is remarkable for the axillary buds which become detached and take root to form new plants that flower in from two to three years. Some very fine species are natives of North America, among them *Lilium superbum*, also called Turk's-cap lily, which grows in low ground in the United States, with stems 3 to 7 feet high, and reflexed orange flowers, spotted with black; *Lilium canadense*, the wild yellow lily; *Lilium philadelphicum*, wood lily; *Lilium catesbœi*, southern red lily; etc. Several very fine species have been introduced from Japan, as *Lilium japonicum, Lilium speciosum*, and *Lilium lancifolium*. *Lilium cordifolium* is a magnificent species, native of the Himalayas. *Lilium longiflorum*, var. *harrisii*, the Bermuda Easter lily, is largely grown in greenhouses for winter blooming, especially for the Easter festival. The bulbs of several species are used as food in Oriental countries. Lilies are distributed throughout the north temperate zone and are grown under various conditions of climate and soil. The plants require considerable moisture during their rapid growth, but the soil must be well drained to prevent injury to the bulbs. They are propagated by offset bulbs and single scales. New varieties are grown from seeds. Consult William Goldring, *Book of the Lily* (New York, 1905). See Colored Plates of LILIACEÆ; CALIFORNIA FLORA.

LILY, GIANT, SPEAR, or GIGANTIC. See GIANT (or SPEAR) LILY.

LILY, STONE. See CRINOIDEA.

LIL′Y, or **LILLY**, WILLIAM (c.1468–1522). A celebrated English grammarian, born at Oldham. He graduated at Oxford, afterward traveled in the Orient to perfect his knowledge of the Greek language, and passed a number of years in study at Rhodes, Rome, and Venice. Returning to London about 1509, he taught privately there for some time, was appointed by Colet first head master of St. Paul's School in 1512, and became one of the chief exponents of the "new learning." He was a joint author of the famous *Eton Latin Grammar* and wrote also various Latin pieces, both in prose and in verse. It is probable that he was the first teacher of Greek in London.

LIL′YBÆ′UM PROM′ONTO′RIUM (Lat., from Gk. *Λιλύβαιον, Lilybaion*). The ancient name of Cape Boeo, the western extremity of Sicily. From it to Cape Bon is the shortest distance between Africa and Sicily. Here in 397 B.C. the Carthaginians founded the city of Lilybæum (modern Marsala, q.v.) to take the place of Motye, which Dionysius had destroyed. In 279 B.C. Lilybæum was besieged unsuccessfully by Pyrrhus, and in the First Punic War the Romans endeavored in vain to reduce it; but in the final treaty of peace it was conceded to them. They made it the starting point of the African expeditions, and the strongest fortress and most splendid city in west Sicily. Its massive walls were surrounded by a moat 40 feet deep and 60 feet wide. Consult Otto Meltzer, *Geschichte der Carthager*, vols. i–ii (Berlin, 1879 et seq.), and the article "Lilybæum" in Friedrich Lübker, *Reallexikon des classischen Altertums*, vol. ii (8th ed., Leipzig, 1914).

LILY FAMILY. The common name of Liliaceæ (q.v.).

LILY MAID OF ASTOLAT, THE. Elaine, the maiden who died for love of Lancelot.

LILY OF THE PALACE. See Plate of AMARYLLIDACEÆ.

LILY OF THE VALLEY (*Convallaria majalis*). A well-known ornamental plant, the single representative of its genus, of the family Liliaceæ. It grows in bushy places and woods in Europe, northern Asia, and in the southern Alleghany region of North America, and is also largely cultivated. The plant grows from an underground rootstock, and usually produces two ovate lance-shaped leaves from 6 to 8 inches long. In May or June the scape with its small, white, six-lobed, bell-shaped, drooping flowers appears as a terminal, one-sided raceme. The fruit of the plant is a few-seeded red berry, about as large as a pea. The berries, roots, and flowers have a nauseous, bitter, and somewhat acrid taste, and are credited with purgative and diuretic effects. The flowers are used in the manufacture of *eau d'or*, an esteemed French perfume. Cultivation has given rise to a number of varieties with red, variegated, and double flowers. The plant succeeds almost everywhere, but makes an especially fine growth in moist, shady places on a rich sandy, well-drained loam. It is propagated by the crowns or strong terminal buds (pips) of the rootstocks. These may be obtained from established beds in the fall, but in the United States they are generally imported. The lily of the valley is largely forced by florists, who obtain blossoms nearly all the year round. See Colored Plate of LILIACEÆ.

LIMA, lē′mȧ. A maritime department of Peru, bounded by the Department of Ancachs on the north, Junin on the east, Huancavelica on the south, and the Pacific Ocean on the west (Map: Ecuador, B 6). Area, 13,314 square miles. The surface is very mountainous, and many peaks are covered with perpetual snow. The west part slopes gradually towards the sea, and has a number of fertile valleys along the river courses, although large areas are occupied by sterile sand wastes. Sugar cane is the principal crop raised in the valleys, which are among the most populous regions in Peru. Minerals are supposed to exist in large quantities, but there is very little mining. Pop. (est.), 300,000. The capital is Lima (q.v.). The seaport, Callao, with a few miles of the surrounding country, forms a separate province.

LIMA. The capital of Peru. It is situated on the Rímac, 7 miles from where it flows into the Pacific Ocean and from the port of Callao (q.v.), in lat. 12° 3′ S., long. 77° 8′ W. (Map: Ecuador, B 6). The elevation above sea level is about 500 feet. The climate differs somewhat from that of the arid coast; in winter the air feels even chilly on account of the dense fogs which then prevail, and which render the climate very unhealthful. Rain, however, is unusual. The city is laid out in the form of a triangle, and the streets, though narrow, are straight and cross at right angles. The old city was surrounded by adobe walls built in 1585; they were razed in 1870, and their site converted into boulevards. There are several handsome promenades adorned with shade trees and statues, and numerous squares, the foremost of which are the Plaza de Bolívar, containing a fine equestrian statue of the liberator, and the Plaza Mayor, with a bronze fountain in the centre. On this plaza stand the cathedral and archbishop's palace, the city hall, and the government building. There should also be mentioned the Plaza del Acho, on the north side of the river, the site of the bull ring. There are no parks properly so called, but the Exposition grounds form a beautiful pleasure garden with palaces, pavilions, and statues, besides zoölogical and botanical gardens. The houses of Lima are as a rule roomy two-story structures built in the Spanish style with a central *patio* or courtyard. They are almost invariably built of adobe stuccoed with plaster. Foremost among the buildings stands the cathedral, with a beautiful Moorish façade and two lofty towers; it was begun in 1535 and consecrated in 1625. It was destroyed by the earthquake of 1746, but by 1758 was reconstructed. After the cathedral, the finest church in Lima is probably that belonging to the convent of San Francisco, near the Plaza Mayor; other notable churches are those of the convents of San Agustin, La Merced, and Santo Domingo. Altogether the churches, chapels, etc., of the city number nearly 70. There are several fine hospitals.

The national University of San Marcos, the oldest in America, founded in 1551, has faculties of theology, law, medicine, philosophy and letters, mathematics and science, and political and administrative science. There are also schools of engineering, agriculture, and navigation, a military and a naval academy, and over 100 minor schools. There are, besides, an athenæum, scientific and literary societies, where public lectures are given, and several valuable libraries, among which the foremost is the National Library, which was founded in 1822, and contained 60,000 volumes before it was destroyed by the Chileans in 1880; it now contains about 50,000 volumes. During the present century increasing attention has been given to general elementary education. Lima has developed rapidly in recent years; since the razing of the walls in 1870, the suburbs have thoroughly grown into the city itself, which has been greatly extended. The public works are in good condition; the city is lighted by electricity, and it has an excellent water supply and sewerage system. The water is obtained by direct filtration from the Rímac into subterranean chambers, from which it is brought to the city in pipes and distributed by the gravity system. The Oroya Railway, running from the port of Callao across the Cordilleras, is here intersected by a railroad running northward through the province. The manufactures of the city include furniture, iron and copper articles, pottery, and dyestuffs. Outside the city limits there are important manufactories of textiles, sugar, cocoa, liquors, etc. The population (1913) is estimated at 143,000, the greater part being mestizo or Indian.

Lima was founded in 1535 by Francisco Pizarro, who called it Ciudad de los Reyes (city of the kings). Its later name, Lima, is a corruption of Rímac, the name of the river. During Spanish colonial times it was the capital of the Viceroyalty of Peru, which then included the greater part of Spanish South America. In 1880–81 Lima was occupied by the Chilean army, which destroyed many of its finest treasures and monuments. Consult: E. W. Middendorf, *Peru*, vol. i (Berlin, 1893); C. Pradié-Fodéré, *Lima et ses environs* (Paris, 1897); C. R. Enock, *Peru, its Former and Present Civilization, History and Existing Conditions, Topography and Natural Resources, Commerce and General Development* (London, 1908); id., *The Andes and the Amazon* (ib., 1910).

LIMA, lī′mȧ. A village in Livingston Co., N. Y., 18 miles south of Rochester, on the Lehigh Valley Railroad (Map: New York, C 5). It is the seat of Genesee Wesleyan Seminary. There are extensive insulator works near by, a bottle-washing-machine factory, and large celery and lettuce gardens. The water works are owned by the municipality. Pop., 1914 (local est.), 900.

LIMA, lī′mȧ. A city and the county seat of

Allen Co., Ohio, 81 miles by rail south of Toledo, on the Ottawa River and on the Cincinnati, Hamilton, and Dayton, the Erie, the Lake Erie and Western, the Detroit, Toledo, and Ironton, the Lake Shore Electric, the Western Ohio, the Ohio Electric, and the Pennsylvania railroads (Map: Ohio, B 4). It is the seat of the Ohio State Hospital for the Criminal Insane, one of the largest institutions of its kind in the world. The industries include several large railroad shops, extensive manufactories of locomotives, cars, and machinery, and petroleum refineries. Lima ships large quantities of oil. The water works are owned and operated by the municipality. Pop., 1900, 21,723; 1910, 30,508; 1914 (U. S. est.), 33,904; 1920, 41,306.

LIMA BEAN. See Bean, and Plate of Legumes.

LIMAÇON, lĕ′mȧ′sôɴ′ (Fr., snail). A special form of the Cartesian curves. It was invented by Pascal (1623–62) and named by Roberval. Its rectangular equation is $(x^2 + y^2 - 2ax)^2 = a^2(x^2 + y^2)$ and its polar equation $r = 2a\cos\theta + k$. Consult Brocard, *Notes de bibliographie des courbes géométriques* (Bar-le-Duc, 1897; and supplement, 1899). See Cartesians; Cardioid.

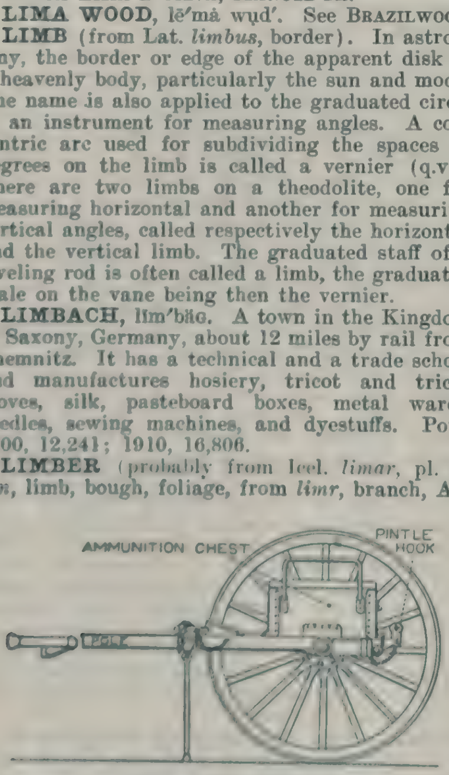
LIMA E SILVA, lē′mȧ ȧ sêl′vȧ, Luiz Alves de. See Caxias, Luiz Alves de Lima e Silva, Duke of.

LIMA E SILVA, Manoel da Fonseca. See Fonseca Lima e Silva, Manoel da.

LIMA WOOD, lē′mȧ wụd′. See Brazilwood.

LIMB (from Lat. *limbus*, border). In astronomy, the border or edge of the apparent disk of a heavenly body, particularly the sun and moon. The name is also applied to the graduated circle of an instrument for measuring angles. A concentric arc used for subdividing the spaces or degrees on the limb is called a vernier (q.v.). There are two limbs on a theodolite, one for measuring horizontal and another for measuring vertical angles, called respectively the horizontal and the vertical limb. The graduated staff of a leveling rod is often called a limb, the graduated scale on the vane being then the vernier.

LIMBACH, lĭm′bȧG. A town in the Kingdom of Saxony, Germany, about 12 miles by rail from Chemnitz. It has a technical and a trade school and manufactures hosiery, tricot and tricot gloves, silk, pasteboard boxes, metal wares, needles, sewing machines, and dyestuffs. Pop., 1900, 12,241; 1910, 16,806.



LIMBER OF FIELD GUN.

LIMBER (probably from Icel. *limar*, pl. of *lim*, limb, bough, foliage, from *limr*, branch, AS. *lim*, Eng. *limb*). The forward element of the gun carriage of a fieldpiece. It is a two-wheeled structure fitted with a box or boxes for the necessary ammunition and a pole or shafts to which the horses are harnessed. Like the caisson, it is a steel chest mounted on a single pair of wheels and is quickly attached to and detached from the gun or caisson by means of a strong hook, known as the pintle hook. During action the horses remain hitched to the limbers, which are detached from the guns and caissons and removed to the nearest place of safety. The number of rounds of ammunition carried in the limber is considerably less than that carried in the caisson (36 as against 70 with the American 3-inch equipment) and is generally reserved for use in an emergency. See Field Artillery; Caisson.

LIMBORCH, lĭm′bôrĸ, Philipp van (1633–1712). A Dutch Protestant theologian. He was born at Amsterdam and was educated at Utrecht University. He served as pastor at Alcmar, at Gouda (1657–67), and (1667–1712) at Amsterdam, where in 1668 he became also professor of theology in the Remonstrant Seminary. His writings include his chief work, *Institutiones Theologiæ Christianæ* (1686; 5th ed., 1735; Eng. trans., 1702); *De Veritate Religionis Christianæ* (1687); *Historia Inquisitionis* (1692; Eng. trans., 1731); *Commentarius in Acta Apostolorum et in Epistolas ad Romanos et ad Hebræos* (1711).

LIMBS, Artificial. See Artificial Limbs.

LIMBURG, lĭm′bụrĸ, Josef Wilhelm Carl (1874–). A German sculptor. He was born at Hanau-on-the-Main, and studied there at the Royal Academy and later under Tilgner in Vienna and Janensch in Berlin, where he won the Roman prize in 1900. After spending a number of years at Rome, he located definitely at Berlin. Among his principal works are the marble monument to Pope Gregory XIII, in the vestibule of the German College in Rome (1901); half-length portrait statue of Pope Pius X (1904), in the Vatican (replica in the Museum of Grottaferrata); portrait statue of the sculptor Gerhardt (1902), in the Accademia di San Luca, Rome; marble bust of Minister of State Von Delbrück (Imperial Bank, Berlin); monument of Count and Countess Ballestrem, in Ziegenhals; statue of Arnold Borsig, on the Borsig Bridge, Berlin, and a Madonna, in the church of Zehlendorf. His ideal works include the bronze groups "Repentance" and "The Power of Sounds."

LIMBURG-ON-THE-LAHN. An old episcopal town in the Province of Hesse-Nassau, Prussia, 32 miles east of Coblenz. The river is here crossed by a bridge dating from 1315. The town has a magnificent cathedral, originally erected in the thirteenth century, and now restored. It is built in Transition style, with seven towers. There are a seminary for priests, an old castle, a new town hall, a Gymnasium. The town produces machinery, tinware, soap, and bricks. There are in the vicinity large iron mines, with foundries and large railway shops. Pop., 1900, 8465; 1910, 10,965. Limburg has in its possession the famous fourteenth-century historical document known as the "Limburger Chronik" or "Fasti Limburgenses," which contains interesting information about German folklore and music of the fourteenth century.

LIM′BUS (Lat., border). The name assigned in Roman Catholic theology to that place or condition of departed souls in which those are detained who have not offended by any personal act of their own, but nevertheless are not admitted to the divine vision. A distinction is made between *limbus patrum* and *limbus in-*

fantum. By the former name is understood the place of the just who died before the coming of the Redeemer, and of whom it is said (1 Pet. iii. 19) that he preached to those spirits that were in prison. By the latter is meant the place or state of souls of infants who die without baptism, and who suffer no torment, but are not considered capable of the beatific vision of God which is the chief joy of heaven. See INTERMEDIATE STATE; HELL.

LIME (Fr. *lime,* from Pers. *līmū, līmūn,* lemon), *Citrus medica acida,* also called *citrus aurantifolia.* A small tree of the same species as the lemon, seldom more than 8 feet in height, with an irregular spreading habit of growth and crooked trunk. The fruit is similar to that of the lemon, but smaller and more nearly globular in outline, more acid and with a thinner rind. The plant is a native of India and China, cultivated in the south of Europe, the West Indies, and Florida, where it is frequently found as an escape. The lime is chiefly valued as a source of citric acid and for lime juice, which is extensively used on shipboard as an antiscorbutic. It is also used to make limeade, a pleasant beverage. The limes on the American markets are mostly derived from Florida or the West Indies. The lime is propagated by cuttings or buds like the lemon and requires similar treatment as an orchard tree. See Colored Plate of CITRUS FRUITS.

LIME, or CALCIUM OXIDE, CaO. A well-known compound of calcium and oxygen, produced by heating some form of calcium carbonate or calcium nitrate. Being an energetic base, lime readily combines with acids, even carbonic acid, and hence is not found free anywhere in nature. The forms of calcium carbonate technically used for the manufacture of lime, all more or less impure, include limestone, marble, calc-spar, sea shells, etc. The best lime is yielded by the densest limestones, the quality of the lime depending further upon the duration of the heating process and the degree of heat to which the limestone is subjected. The heating process is carried out in kilns, a good draft being required to render it effective. It is well that the limestone should contain a certain amount of moisture, the latter aiding the decomposition of the carbonate. Various methods have been devised for adding moisture to the carbonate during the process of heating; thus, a current of steam passed over the carbonate, or a spray of water thrown upon it from time to time, accelerates the process very effectively. The limestone was formerly heated in heaps or ditches, but at present this is scarcely ever practiced on a large scale, the process being carried out in either intermittent or continuous kilns, the type of which is chosen according to the available fuel. The most efficient kiln is the ring kiln, or Hoffmann kiln. (See KILN.) Nearly as efficient, and more generally used, are vertical chamber kilns. (See KILN, *Continuous Kilns.*) The kilns may be provided with fireplaces, the fuel and the limestone being separated; or else there may be no separate fireplace, the limestone being charged together with the fuel. The latter form of kilns is convenient for most ordinary purposes; but if it is desired to produce a lime of high quality and of a pure white color, fireplace kilns alone should be employed. An economical form of kiln largely used at present is the iron-shell draw kiln, which holds the materials in a shell of heavy tank iron.

Pure calcium oxide (quicklime, or burned lime) is a perfectly white substance having the specific gravity 3.15. It is not affected by heat. When brought into contact with water, it forms the hydroxide $Ca(OH)_2$, commonly known as *slacked lime,* the ease with which the transformation takes place depending largely upon certain details of the process employed in making the quicklime, such as the duration of the process, the degree of temperature, etc. Calcium hydroxide has a much lower specific gravity (2.08) than quicklime. When shaken up in water, it remains in suspension for a considerable length of time, forming what is known as milk of lime. A small amount of the lime actually goes into solution and on filtering may be precipitated by carbon dioxide, with which the hydroxide readily forms calcium carbonate, while quicklime refuses to absorb the gas at ordinary temperatures. Unlike that of most other substances, the solubility of lime in water decreases as the temperature increases, and hence clear limewater becomes turbid when boiled. When mixed with peroxide of hydrogen, limewater yields an unstable hydrated *calcium peroxide,* $CaO_2.8H_2O$, which separates in the form of minute crystals.

Lime is used for a variety of purposes in the arts. It is much used in the production of raw cane sugar chiefly for the purpose of neutralizing the organic acids present in the extracted juice, forming with them chemical compounds that can be readily separated. It is also used in the purification of molasses and cane and beet sugar of inferior grades. To recover the sugar, the lime compound is treated with carbon dioxide, which combines with the lime and sets free the sugar. Strontia can be used instead of lime. Lime is extensively used in making mortars and cements for building purposes and in manufacturing artificial stone and glass. It is often employed as a medicinal agent, being prepared for this purpose from the purest varieties of calcium carbonate. It is prescribed mainly in the forms of limewater (sometimes mixed with glycerin), lime liniment (carron oil, made by mixing equal volumes of limewater and linseed oil), sirup of lime (made up of lime, sugar, and water), and Vienna paste (lime and caustic potash). Lime liniment is used for burns, although a strong solution of picric acid (q.v.) is preferred by many. A mixture of limewater with glycerin is useful in weeping eczema. Limewater (with milk) is also often administered internally, especially for the purpose of allaying vomiting in infants. A saturated solution of saccharate of lime in calcium hydroxide, commonly known as viscogen, has been used to increase the viscosity of separator cream. For this purpose 0.5 to 0.75 per cent is employed. Lime is the most important alkaline material for technical purposes. Among its many uses may be cited, first, softening of water; second, preparation of caustic soda or potash lye for any purpose, both depending on the removal of carbon dioxide in the form of insoluble calcium carbonate; third, neutralization of excess acid in soil and increase of available calcium plant food; fourth, base for the formation of acid calcium sulphite in wood-pulp process; fifth, development of gaseous ammonia. The carbon dioxide produced in the manufacture of lime may be collected and utilized. (See CARBONIC-ACID GAS.) Consult: Q. A. Gillmore, *A Practical Treatise on Limes* (New York, 1896); Frash, "Lime and Lime Burning," in *The Mineral In-*

dustry (ib., 1899); F. H. Thorp, *Outlines of Industrial Chemistry* (ib., 1911); Sir T. E. Thorpe, *Dictionary of Applied Chemistry* (ib., 1912). LIME, Chloride of. See Hypochlorous Acid; Bleaching Powder.

LIME′LIGHT′. See Drummond Light.

LI′MEN (Lat., threshold). A metaphorical expression introduced into psychology by Herbart. The ideal boundary or limit, which ideas or representations may be said to cross on becoming conscious, was termed by him the "limen of consciousness." The word was then transferred by Fechner to psychophysics, where it is now employed in two principal connections. 1. The effect of a stimulus upon the organism may, for various reasons, be so slight as to produce no change in consciousness. A sound may be too faint, a point of light too small, a scent too weak, to arouse the corresponding sensation; or, on the affective side, an occurrence in the outside world may be of so little importance to us that we take it indifferently, are not "affected" by it whether pleasantly or unpleasantly. All stimuli of this kind are called subliminal. On the other hand, stimuli of a certain intensity or duration or extent, and occurrences of a certain importance, never fail under ordinary circumstances to evoke a conscious response; such stimuli are called supraliminal. Between the two lies the ideal and variable stimulus which is just able to arouse a sensation or induce an affection. This just noticeable stimulus, or *stimulus limen,* may be defined as the stimulus which calls forth the judgment "present" in one-half of a long series of observations, while in the other half the judgment is "absent" or "doubtful": such a stimulus value may be taken as the mathematical equivalent of the stimulus which, if all sources of error were eliminated, would in fact be just noticeable, barely perceptible. In the sphere of sensation the limen may be intensive, qualitative, extensive, or temporal. We may seek to determine, e.g., the least intensity of pressure that will excite a sensation in the cutaneous pressure organs, or the least intensity of sound that can still be heard; the smallest area of pressure or of light that is able, under constant conditions of duration and intensity, to produce sensation; the least number of air vibrations that can arouse the tonal quality with which their period corresponds; the least duration of a given color or temperature that can evoke its appropriate sensation. The limen of attributive clearness seems not to have been investigated, though there is ground for the belief that it is closely bound up with the limen of intensity. The affective limens, also, owing in part to difficulties of experimentation, but chiefly to the dependence of the affective reaction upon the whole contents of consciousness, have not yet been worked out. 2. What holds of stimuli holds, further, of differences between stimuli. Two colors may be so nearly alike as to be sensed identically; the difference of stimuli is subliminal. Or they may be so different as normally to be sensed differently; the difference of stimuli is supraliminal. Between the two lies a color difference that (in the sense already explained for the stimulus limen) is just noticeable; such a difference is called the *difference limen.* The ascertainment of this value is of extreme importance in psychophysics; its absolute or relative constancy, for a series of stimulus values, determines the absolute or relative constancy of the sensible discrimination. (See Discrimination, Sensible.) It may be determined for any attribute of sensation and, in theory, for the attributes of affection. The most elaborate of the metric methods of psychophysics (q.v.) are concerned with it.

The concept of the limen has played no considerable part in functional psychology. Wundt distinguishes the limen of consciousness from that of attention or apperception; any impression which has passed the limen of consciousness is able, "provided the subjective factor of attention be superadded," to pass the limen of apperception. This view is connected with his peculiar theory of apperception, and more especially with his psychological interpretation of Weber's Law (q.v.). Consult: J. H. Herbart, *Sämmtliche Werke,* vol. v (Leipzig, 1886); E. B. Titchener, *Experimental Psychology,* vol. ii (New York, 1905); G. T. Fechner, *Elemente der Psychophysik,* vol. i (3d ed., Leipzig, 1907); Wilhelm Wundt, *Physiologische Psychologie* (ib., 1908–11); Oswald Kuelpe, *Outlines of Psychology,* translated by E. B. Titchener (New York, 1909).

LIME PLANTS. Plants which grow naturally in soils or rocks rich in calcareous compounds. See Rock Plants.

LIM′ERICK. An inland county of the Province of Munster, Ireland, separated by the Shannon on the north from Clare and bounded east by Tipperary, south by Cork, and west by Kerry (Map: Ireland, C 6). Area, 1064 square miles. A mountainous district on the west belongs to the great coal tract of Munster, but the coal is of an inferior quality and is chiefly used for the burning of lime. The soil in general is fertile, especially in the district called the Golden Vale. The river Shannon is navigable for seagoing vessels as far as the city of Limerick. The agriculture of the county is backward, and two-thirds of the area is devoted to grazing; pigs and poultry are largely raised. The capital is Limerick. Pop., 1841, 331,000; 1901, 146,000; 1911, 142,846.

LIMERICK. A city, civic county, and port, capital of County Limerick, Ireland, on the Shannon, 120 miles west-southwest of Dublin (Map: Ireland, C 6). It occupies both sides of the river, together with King's Island. It is divided into the English town, the oldest part of the city connected with the extensive suburb of Thomond Gate on the Clare side of the Shannon, and the Irish town, which extends on the south bank of the river into Newtown Pery, the best part of Limerick. The gas works, water supply, and other public utilities are municipal property. Among the noteworthy buildings are St. John's Catholic Cathedral and St. Mary's Anglican Cathedral, dating from 1179. Limerick is a military station for infantry, artillery, and cavalry, with barracks within the walls of King John's Castle, an important and well-preserved old Norman fortress defending Thomond Bridge. The Shannon, crossed by several bridges, is navigable for ships of large burden and is connected with Dublin by the Grand Canal in King's County and the Royal Canal near Longford.

The river is canalized to the head of Lough Allen. The graving dock admits vessels of 2500 tons, and there is a patent slip for vessels of 500 tons and a floating dock for vessels of 3000 tons. The industries include the manufacture of the celebrated Limerick fishhooks, flour milling, bacon curing, lace manufacturing, tanning, etc. The manufacture of clothing for the British army gives employment to more than 1500 persons, and there is a flourishing butter and condensed-milk industry. A large import trade is carried on, Limerick ranking fourth among Irish ports. The chief exports are oats, bacon, butter, condensed milk, and salmon; imports, grain, petroleum, sugar, and timber. The United States is represented by a consular agent. The ancient Regia of Ptolemy, Limerick, from its position on the Shannon, was long an object of desire to the Danes, who occupied it in the middle of the ninth century and held possession till reduced to a contributary condition by Brian Boroimhe in the tenth century. It was early occupied by the English, and in 1210 King John visited and fortified it. It was assaulted and partially burned in 1314 by Edward Bruce. It was occupied by the Roman Catholic party in 1641, but surrendered to Ireton in 1651. At the Revolution it was the last stronghold of King James. Having been unsuccessfully besieged by William after the victory of the Boyne, it was regularly invested in 1691 by General Ginkel, and after a vigorous and brilliant defense of several weeks an armistice was proposed, which led to the well-known Treaty of Limerick, the alleged violation of which has been the subject of frequent and acrimonious controversy between political parties in Ireland. The so-called "treaty stone" still marks the spot, near Thomond Bridge, at the entrance of the suburb, near Thomond Gate, where this treaty was signed. Pop., 1901, 38,151; 1911, 38,518. Consult Maurice Lenihan, *Limerick: Its History and Antiquities* (2d ed., Dublin, 1884), and John Begley, *Diocese of Limerick, Ancient and Medieval* (ib., 1906).

LIMERICK, EARL OF. See DONGAN, THOMAS.

LI'MES GERMAN'ICUS, or **LI'MES ROMA'NUS.** The name given to the elaborate fortifications built by the Romans to protect the provinces of southern Germany and Rhætia against the Germans; they extended from a point near Bona, on the Rhine, to a point near Regensburg, on the Danube, a distance of about 336 miles. The limes comprised a strong wall, with blockhouses and camps at regular intervals. An excellent idea of the limes may be obtained as the result of German excavations made on the site of one of the camps, at Saalburg, near Homburg. Emperor William II took a deep interest in the excavations here and caused the camp to be completely restored. A model of the restored camp was exhibited at the St. Louis Exposition (1904) and subsequently purchased by a citizen of St. Louis and presented to Washington University there. Consult, for a description of the limes and of the restored camp at Saalburg, F. W. Shipley, in *The Classical Weekly*, vol. ii (New York, 1908–09); also H. F. Pelham, *Essays on Roman History* (Oxford, 1911).

LIME'STONE. The name given to rocks which are composed of lime carbonate. They may contain variable amounts of carbonate of magnesia and by an increase of the latter grade into dolomite. Silica, alumina, and ferric oxide are likewise present in variable amounts, and by an increase of these transitions into sandstone or shale are seen. Phosphate of lime is present in some, occasionally in considerable amounts, and carbonaceous matter, at least in small quantities, is often detected. Silicate minerals occur only in those limestones that have been changed by contact or regional metamorphism.

The variable composition of limestone is brought out by the following analyses:

	1	2	3	4	5	6	7
SiO_2...	0.54	0.06	3.83	7.60	6.22	28.72	15.37
Al_2O_3..	0.42	0.80	2.31	0.75	1.70	12.28	9.13
Fe_2O_3..					0.86	5.22	2.25
CaO ..	54.73	55.00	52.16	50.05	47.86	25.54	25.50
MgO..	0.19	....	0.14	0.30	0.04	1.10	12.35
CO_2...	43.22	43.22	41.64	41.30	42.11	24.40	34.20

1, nearly pure limestone, Ilasco, Mo.; 2, bog lime, Newaygo, Mich.; 3, chalk, Yankton, S. Dak.; 4, hydraulic limestone, Malain, France; 5, impure bog lime, Montezuma, N. Y.; 6, natural cement rock, Cumberland, Md.; 7, magnesian clayey limestone, Rondout, N. Y.

Properties of Limestone. Limestones vary in hardness from soft white powdery materials (bog lime) through those of medium hardness to others of great hardness and density. They are usually crystalline, but not always visibly so, this texture being best seen in the metamorphosed ones. Some are oölitic, and others are made up wholly or in part of shell and coral fragments.

Pure limestone is white, but the presence of even small amounts of carbonaceous matter may color it black, gray, or blue, and iron will tinge it brown, yellow, or red. The texture varies from coarse to fine; the layers range from massive to shaly. Limestone effervesces readily with cold hydrochloric acid unless it is magnesian, when only warm acid attacks it. Most limestones are easily soluble in water containing a slight quantity of carbonic or other acids, and hence their surface is sometimes quite uneven. The easy solubility of the rock has led to the formation of caves and sink holes.

Distribution. Limestones show a wide geological distribution, being found in every system, but their greatest development is among the Paleozoic formations, where a series of calcareous beds may sometimes attain a thickness of several hundred feet. The older limestones geologically are commonly crystalline, due to regional metamorphism, but the later ones may at times be so either from this same cause or from contact metamorphism. The geographic distribution of limestones is equally great.

Origin. Limestone may be formed in several ways: 1. By the accumulation of organic remains or the growth of colonies with calcareous skeletons; the former manner of origin is illustrated when shell fragments and foraminiferal cases collect on the ocean bottom, and the latter is shown in the growth of coral reefs. These fragments are often visible in unaltered limestones, but metamorphism and recrystallization tend to destroy them. Hence we rarely find fossils in marbles. Some of the chert or flint found in limestones is due to silica-secreting organisms. 2. By chemical precipitation. Many spring waters hold lime in solution in the form of bicarbonate, but this compound on coming in contact with the air is broken up and lime carbonate precipitated. The same change is also caused by certain minute algæ and other plants found growing in ponds. The effect of plant action is seen in the accumulation of boglime in the bottom of many ponds. The lime carbonate deposited by springs often forms beautiful incrustations on mosses and other objects. 3. By mechanical means. Calcareous rocks are broken down by wave action, and the fragments strewn over the ocean bottom in time may form extensive strata. The high percentage of magnesium carbonate found in some limestones may be due to secondary changes, and the alteration of limestone to dolomite may be accompanied by a decrease in volume.

Limestones are found in many States, but are especially abundant east of the Mississippi, underlying large areas in the Eastern and Central States. An important group known as the Shenandoah follows the Great Valley from New York to Alabama, while in the Central States extensive deposits occur in the Mississippian or lower Carboniferous.

Varieties of Limestone. A number of names have been given to different varieties of limestone, of which the more important are the following: *Bog lime*, a soft, calcareous mud, formed in the bottom of many ponds. *Crinoidal limestone*, a variety containing fragments of crinoid stems. *Coquina* (q.v.), a variety composed of loosely cemented shell fragments, common in Florida. *Chalk* (q.v.), a white variety of limestone, formed chiefly of foraminiferal shells. It is known in some of the Western States, but the best-known formations are those of southern England, France, and Denmark. *Dolomite* (q.v.), a limestone containing both carbonate of lime and magnesia. *Hydraulic limestone*, an aluminous variety having the property of hardening under water after it has been burned. *Lithographic limestone*, a fine-grained limestone used for lithographic work. *Marl* (q.v.), a calcareous clay. *Marble* (q.v.), strictly speaking, is a crystalline metamorphic limestone, but the term has been expanded in commercial use to include any limestone that will take a polish. *Oölite* (q.v.), a limestone composed of small spherical grains. *Saccharoidal limestone*, a coarsely granular variety. *Travertine* or *calcareous tufa*, calcareous deposits formed around the mouths of springs. Extensive deposits occur near Tivoli, Italy.

Uses. The chief use of limestone is for building purposes, for which it is found especially valuable on account of its wide distribution, dense structure, and massive character. Marble is used for both structural and decorative work. Limestone is also widely used as a road material. Limestones are extensively used in their calcined form. A limestone free from clay will, when heated to about 800° C., yield lime (q.v.), which slakes when mixed with water, but whose several properties vary with the amount of magnesia present. If the rock contains an appreciable quantity of clayey impurities, then after calcination to the proper temperature it no longer slakes, but will, if finely ground, form a hard mass or set, when mixed with water. This product is known as hydraulic cement. Natural-rock cement, such as the Rosendale or Louisville type, is made by calcining a clayey limestone, which may be high or low in magnesia. Limestone low in magnesia, when mixed with the proper amount of shale or clay and burned at a high heat, forms Portland cement. Other uses of limestone are as a flux in iron and lead smelting and in glass manufacture. When burned to lime, it is employed for making mortar and chloride of lime, and is used in gas, soap, and sugar manufacture, as a disinfectant, for bleaching, in the manufacture of Bessemer steel, etc. The total value of the limestone produced in the United States in 1913 and used chiefly for structural and road material was $38,745,429. Of this amount $11,103,989 represented the value of stone sold for lime for blasting-furnace flux, and $387,724 for sugar factories. Much of the limestone quarried is now ground and sold for agricultural purposes, and this formed $493,718 of the total production.

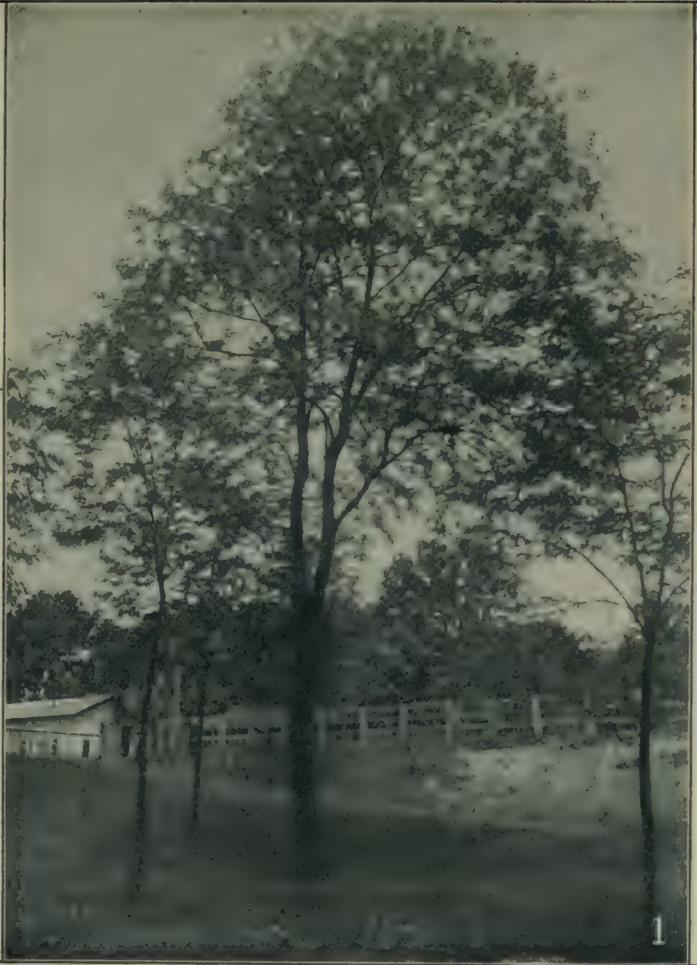
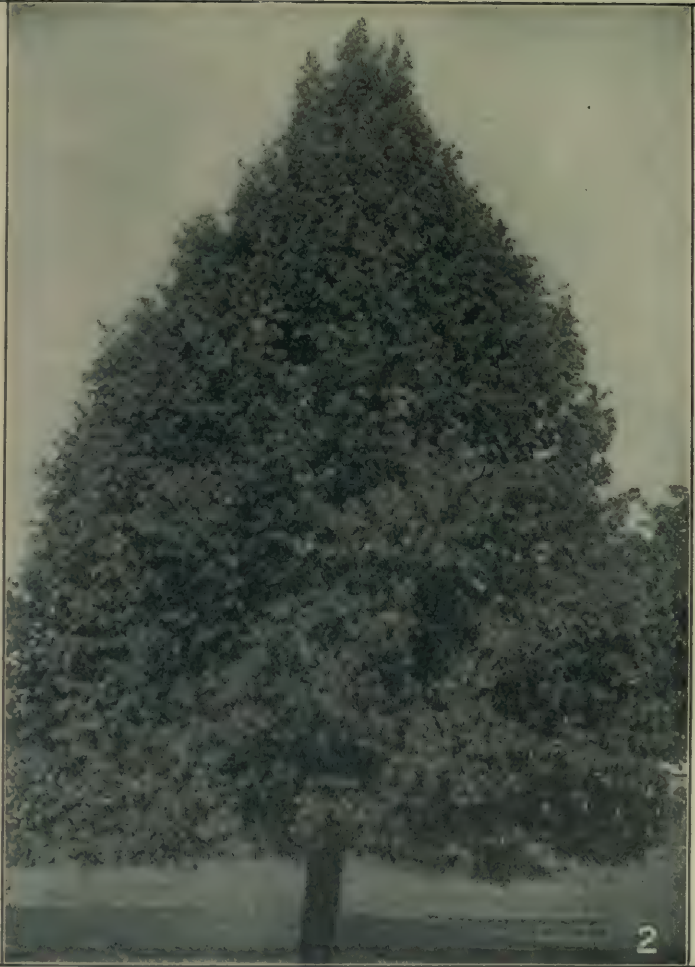
LIME TREE, LINDEN, LINN or BASSWOOD (AS. *linden*, from *lind*, *linde*, Icel. *lind*, OHG. *linta*, Ger. *Linde*, linden; probably connected with Gk. *ἐλάτη*, *elatē*, silver fir). A name given to trees of the genus *Tilia*, of the family Tiliaceæ, natives of Europe, the north of Asia, and North America. The species, which number about a dozen, are very similar—graceful, umbrageous trees, with deciduous heart-shaped, serrated leaves, and cymes or panicles of rather small yellowish flowers, each cyme or panicle accompanied with a large, oblong, yellowish, membranous bract with netted veins, the flower part of which adheres to the flower stalk. The wood is light and soft, tough, durable, and particularly suitable for carved work, and is much used by turners. The charcoal made of it is often used for tooth powder, for medicinal purposes, for crayons, and for the manufacture of gunpowder. The fibrous inner bark is used for making ropes, mats, and other plaited work. It is also used as a healing application to wounds and sores, being very mucilaginous, and containing a bland sap. The flowers have an agreeable odor, and abound in nectar much sought after by bees. The celebrated nectar, much valued for medicinal use and for making liqueurs, is the product of great lime forests near Kovno in Lithuania. The seeds contain a fixed sweet oil. The European lime or linden (*Tilia cordata* and *Tilia platyphyllos*) often attains a large size, particularly in rich alluvial soils. Some botanists distinguish a small-leaved kind (*Tilia parvifolia*) and a large-leaved (*Tilia grandifolia*) as different species; others regard them as mere varieties. The hooded or capuchin lime is an interesting mountainous variety. The lime tree

LOCUST AND LINDEN

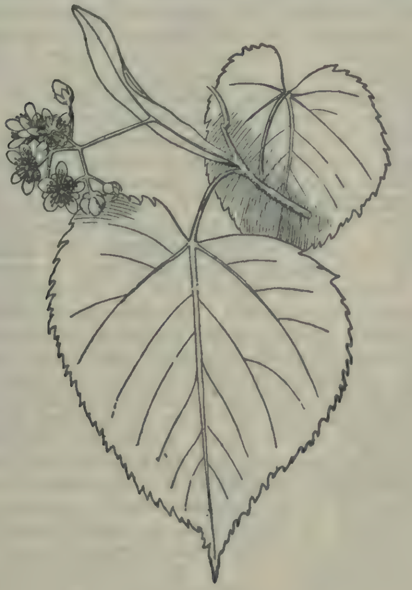


1. LOCUST



2. LINDEN

is often planted for shade in towns; and the principal street of Berlin is called *Unter den Linden*, from the rows of lime trees which line it. The American lime (*Tilia americana*), commonly called whitewood or basswood in America, has larger leaves than the European species. It is found from New Brunswick to Virginia, and in the elevated parts of Alabama and Georgia, westward to Minnesota and Texas. It reaches a height of 80 feet or more and 4 feet in diameter. The wood is fine, close-grained and soft, easily worked, and is extensively used for furniture, carriage boxes, turning, etc. The tree is considered especially valuable for street planting, as it is hardy, resists drought, and is less liable to injury than many others. A similar species is the white basswood (*Tilia heterophylla*), which occurs from Pennsylvania to Florida and westward through Indiana and Illinois to Texas. It is similar to the above in its properties and characteristics. The species of basswood have been tried for paper pulp, but the quality furnished was considered inferior to that obtained from spruce.



LINDEN.

LIMFJORD, lĭm′fyôrd. A narrow passage extending from the Cattegat to the North Sea and cutting off the northern part of Jutland from the mainland (Map: Denmark, B 2).

LIMIC′OLÆ (Neo-Lat., from Lat. *limus*, mud + *colere*, to inhabit). A large order of birds, also called Charadriiformes, and in common parlance the plover-snipe group, differing from other wading birds chiefly in their breeding habits. They lay few eggs, usually four, and the young when hatched are at once able to run about and look out for themselves. The body is rounded or depressed, never notably compressed, as in the rails. The members of most species are of small size, and are usually found in open places near bodies of water. They feed on insects and worms and other small animals, for the capture of which their long, slender, and sensitive bills are admirably fitted. The order is a large one and includes about a dozen families found in all parts of the world. The best known of these and the most typical are the plovers (Charadriidæ), the snipes, sandpipers, curlews, etc. (Scolopacidæ), and the avocets (Recurvirostridæ). The other families are the pratincoles (Glareolidæ), confined to the Old World; the thick-knees (Œdicnemidæ), with eight species, all but one of which are Old World forms; the jaçanas (Parridæ), rail-like birds of both hemispheres; the sheathbills (Chionidæ), remarkable pure white birds of Kerguelen and the Crozet Islands, two species of which are known; the Thinocoridæ, a family of half a dozen gallina-like South American birds; the crab plovers (Dromadidæ), only one species being known, an inhabitant of India and Africa; the Hæmatopodidæ or oyster-catchers, with six or eight cosmopolitan species; the Phalaropodidæ, with three boreal species, easily recognized by their lobate feet; and lastly and doubtfully the Old World bustards (Otididæ), which are perhaps more nearly related to the cranes. See Plates of BEACH BIRDS, and of SHORE BIRDS.

LIMITATION. See LIMITATION OF ESTATES.

LIMITATION, CONDITIONAL. See CONDITIONAL LIMITATION.

LIMITATION OF ACTIONS (Lat. *limitatio*, a bounding, from *limitare*, to bound, from Lat. *limes*, boundary; connected with *limen*, threshold). The limitation by law of the time allowed to a party in which to commence an action after his cause of action has accrued. Owing to the difficulty of preserving evidence for long periods of time, and to prevent the disturbance of rights which have been long enjoyed and acquiesced in, sound policy requires that some limit should be placed upon the time within which actions may be brought. Equity, recognizing the justice of such a doctrine, early refused relief to a plaintiff when guilty of long and inexcusable delay in asserting an alleged right (see LACHES), but the limitation of actions at law is purely statutory. Statutes of limitation were enacted in the time of Edward I and Henry VIII, and these were revised by the Statute of Limitation passed in the twenty-first year of James I (1624), which, with slight modification, has been reënacted in most of the States of the United States.

The following are the more important periods of limitation which, with some variation, have been adopted in England and the United States. Actions affecting the title to real estate, or founded upon a contract under seal, must be brought within 20 years. Similar actions affecting the title to personal property, and actions founded upon contracts not under seal, within six years, and those founded upon personal tort, within two years. In many States the time for bringing equitable actions is limited to 10 years; and in most States there are short periods of limitation for actions against administrators and executors.

An action is deemed to be begun for the purpose of avoiding the statutory limitation by the delivery of the writ or summons to the sheriff or other proper officer for service. The action is not then barred by the statute even though service of process is not made until after the expiration of the statutory period. A person under a legal disability (as infancy, insanity, or, formerly, coverture or absence from the jurisdiction) is not barred from his action by any lapse of time so long as the disability continues, but is allowed additional time, sometimes the full period of limitation, sometimes a shorter period fixed by the statute, after the disability has come to an end, in which to assert his right to relief.

The period of limitation runs from the time that the cause of action accrues. In the case of actions founded on the right to possession of property, whether real or personal, the cause of action accrues with the adverse possession of the property. In the case of both real and personal property uninterrupted adverse possession for the statutory period in effect vests the party in possession with a perfect title, as the real owner is barred from bringing an action.

In the case of land possession must be of definitely bounded or ascertained property and it must in any case be against the consent of the owner. The possession of a tenant or of a mortgagor, being with the consent of the owner and the mortgagee respectively, is not adverse, and is not affected by the statute.

In the case of actions founded upon contract the statute runs from the time when the defendant is bound to perform the contract. Thus in case of negotiable paper the statute begins to run when the paper becomes due. In case of open or running accounts the statute runs from the date of the last item of the account. In the case of obligations to pay money a payment of interest or of a part of the principal forms a new due date from which the statute begins to run anew, and a promise made by the debtor or obligor after the expiration of the statutory period revives the debt or obligation.

In the case of torts the right of action accrues and the statute runs from the time when the tortious act takes effect or results in the injury complained of.

In most jurisdictions the defense of the Statute of Limitations is not available to the party entitled to avail himself of it unless set up by him as a defense and generally the burden of proof is upon him to make good the plea. Consult: Wood, *A Treatise on the Limitation of Actions* (Boston, 1901). See Pleading.

LIMITATION OF ARMAMENT. See Supplement.

LIMITATION OF ESTATES. In the common law of real property, the fixing of the quality or quantum of a freehold estate by the terms of the conveyance by which it is created. Inasmuch as the nature of an estate conveyed resulted from the use of appropriate terms of limitation, the phrase came to be employed in the more general sense of a conveyance, and accordingly an estate for life or in fee (but never an estate for years) was said to be limited, i.e., conveyed or granted to or vested in a person. An estate is limited to a person in fee if the conveyance contains words of inheritance, as to John Doe and his heirs (fee simple), or to John Doe and the heirs of his body (fee tail), and for life if it lacks words of inheritance, or, generally in modern law, if it contains the words "for life." The term has, however, gone out of common use except where an estate is limited to come to an end upon some future event other than that (the death of a life tenant, the failure of heirs of a tenant in fee, etc.) which would naturally determine it, as where lands are given to A and his heirs so long as the property shall be used for a specific purpose. Such a conveyance creates what is known as an estate on collateral limitation, the proviso or limitation which may determine it being collateral to the estate created, which is a fee simple naturally terminable only by the failure of heirs of the person last seised. So a devise of lands to a widow so long as she shall remain unmarried creates a life estate on collateral limitation, i.e., one which will naturally endure so long as she lives but which will ipso facto be determined in the event of her marriage. Such estates are also known as estates on conditional limitation. Some recent authorities, however, employ the latter expression in a distinctive sense to describe the future estate which accrues to a person on the shifting of a fee from a previous holder, as where lands are given to A in fee but with the proviso that if he die without issue surviving the estate shall go to B. In this case B is said to acquire an estate on conditional limitation. See Estate; Fee; Reverter, Possibility of; and authorities referred to under Real Estate; Property.

LIMITED COMPANY. A company whose liability is limited to the amount of its capital, and whose stockholders are exempt from liability beyond the amount which they have invested in the company as represented by the stock held by them respectively. In this respect limited companies partake of the nature of corporations. The term is most frequently applied to joint-stock companies limited, which are organized under modern statutes, or to limited partnership associations, also creations of modern legislation. See Joint-Stock Company; Partnership; Corporation; and authorities there cited.

LIMITED LIABILITY. Pecuniary liability limited to the amount which a person has invested in a joint-stock or other enterprise. At common law, this could be secured only by a special contract; i.e., by one to which both parties expressly assented. If an insurance or banking partnership wished to limit its liabilities to its assets, and save its members from personal responsibility for its debts, it was bound to notify the insured, or the bank depositor or holder of bank bills, as the case might be, that it would contract with him only on that basis. Under modern statutes, however, authorizing the formation of joint-stock companies (see Joint-Stock Company) and limited partnerships (see Partnership), the term "limited liability" is imported into all contracts made with such associations. Persons dealing with them are bound to take notice of the privilege so accorded to them; but as this privilege is statutory, it avails only those who have complied with the legislative requirements. Thus, if a limited company in England omits the word "limited" from its name, its shareholders are bound to pay its debts in full.

By the general maritime law (q.v.) of Europe, a shipowner can absolve himself from liability for the negligence of the master or crew by surrendering the ship and the freight. This rule has been adopted by Parliament in England and by the Congress of the United States. (See 7 Geo. II, c. 15.) Its present provisions are found in the Merchant Shipping Act, 1894 (57 and 58 Vict., c. 60), as amended by various acts, especially by Merchant Shipping Act, 1900 (63 and 64 Vict., c. 32). Congressional legislation on this topic began in 1851, and is now embodied in the United States Revised Statutes, §§ 4282 to 4289, as amended. Under it "the owner of any vessel, whether steamer or canal boat, employed whether in seagoing or inland navigation, whether he be an American citizen or a foreigner, may obtain a limitation to the value of his interest in the vessel and her pending freight, of his liability not only for the results of a single disaster, but for the results of a disastrous voyage, including all debts due on account of the vessel save seamen's wages." These statutory provisions apply to liability for personal injury and death, as well as for damage to property. If the ship and freight are lost, the owner must abandon to the injured parties all claims and causes of action having reference to the vessel and freight. If he collects these he is liable to the injured parties to the extent of the proceeds.

It is to be noticed that this limitation of liability is confined to the owners of the vessels who are not in charge thereof. The master and seamen whose misconduct causes the injuries are not exempted from liability by maritime law or by statute. Consult E. C. Benedict, *The American Admiralty, its Jurisdiction and Practice* (New York, 1898).

LIMITED PARTNERSHIP. See LIMITED LIABILITY; PARTNERSHIP; SOCIÉTÉ EN COMMANDITE.

LIMITS, THEORY OF. When the difference between a variable and a constant quantity may become and remain less in absolute value than any assignable quantity, however small, the constant is called the *limit* of the variable; e.g., the sum of two, three, four, . . . n terms of the series $\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\frac{1}{16}+\ldots$ is a variable which, by taking n sufficiently large, may be made to differ from 1 by less than any assignable quantity. The variable may be always less than, always greater than, or sometimes greater and sometimes less than, its limit. The series $1-\frac{1}{2}+\frac{1}{4}-\frac{1}{8}+\ldots$ is an example of the last, since the limit is $\frac{2}{3}$, while the sums to one, two, three, etc., terms are $\frac{1}{2}$, $\frac{3}{4}$, $\frac{5}{8}$, etc. The symbol $\doteq$ is used to indicate that a variable approaches a constant as a limit; e.g., $\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\ldots\doteq 1$. In algebra the limit of a given function $f(x)$ when $x \doteq a$ is defined thus: If for any positive value e, however small, a number α can be found such that for all values of x satisfying the inequality $|x-a|<\alpha$ the corresponding values of $f(x)$ satisfy the inequality $|f(x)-b|<e$, then b is called the limit of $f(x)$. E.g., let $f(x)=x^3$, and suppose $x\doteq 0$; select e as 0.001; then (1) $|x-0|<\alpha$ (2) $|x^3-0|<0.001$, show that for $\alpha=0.1$ any value of x satisfying (1) gives an x^3 satisfying (2), therefore, by making e small enough, $x^3\doteq 0$ as $x\doteq 0$. (The notation $|x|$ stands for the *absolute value* of x.)

The fundamental propositions of limits are: 1. If two variables are always equal or in a constant ratio as they approach their limits, their limits are equal or are in the same ratio. 2. The limits of the algebraic sum of a finite number of variables is the sum of their limits. 3. The limit of the product of a finite number of variables is the product of their limits, all the quantities being finite. 4. The limit of the quotient of two variables is the quotient of the limits, if the expression does not assume the form $\frac{0}{0}$ or $\frac{\infty}{\infty}$. In case an expression of the form $\frac{f(x)}{\phi(x)}$ becomes $\frac{0}{0}$ or $\frac{\infty}{\infty}$ for a particular value $x=a$ of the variable, the true value is easily found by a rule due to L'Hôpital, which consists in replacing $f(x)$ and $\phi(x)$ by their derivatives, and, if necessary again, by their second derivatives, and so on. For exceptions to this rule and its applications, consult the works mentioned under CALCULUS. See also FRACTION.

The theory of limits is among the most important in mathematics, the rigor of modern analysis depending upon the high state of perfection of this theory. The mensuration of curves and surfaces, the treatment of series (q.v.), and the foundations of calculus (q.v.) rest upon it. The modern method of limits is a development of Newton's theory of prime and ultimate ratios found in the *Principia* (1687).

The *limits of the roots* of an equation are the numbers above and below which it is impossible that the roots should exist. The approximate solution of numerical higher equations consists in bringing the limits of each root as nearly together as possible.

For historical and theoretical discussion, consult Alfred Pringsheim, in the *Encyklopädie der mathematischen Wissenschaften,* vol. i (Leipzig, 1898).

LIM′MA (Lat., from Gk. λεῖμμα, *leimma,* remnant, from λείπειν, *leipein,* to leave). An interval in the musical system of the ancient Greeks which to-day is designated as a *diatonic* semitone (a—b♭), as opposed to the chromatic semitone (a—a♯), which latter the Greeks called *apotome.* In our modern system the diatonic semitone is larger than the chromatic, but with the Greeks it was the reverse. They determined the limma by subtracting two whole tones, each in the proportion of 8 : 9, from the perfect fourth (3 : 4) and thus established the ratio 243 : 256; whereas the apotome or chromatic semitone was fixed in the proportion of 2048 : 2187. See APOTOME.

LIMNÆ′A. See POND SNAIL.

LIMNANDER DE NIEUWENHOVE, lĭm′nän-dẽr dė nē′ven-hō′ve, ARMAND MARIE GUISLAIN, BARON (1814–92). A Belgian composer, born at Ghent. He was educated at the St. Acheul Jesuits' College, near Amiens, afterward at Fribourg, and later studied composition with Fétis. Upon his return to Belgium from Switzerland he began the work of composition, and also conducted an amateur symphonic society at Mechlin. In connection with this he founded a choral society, the Réunion Lyrique, and he wrote some fine choruses for unaccompanied male voices, besides a *Requiem Mass,* with organ; a *Stabat Mater,* with orchestra; a sonata for piano and violoncello; *Les Druides,* operatic scenes, produced at the Paris Conservatory (1845); a symphony called *La fin des moissons;* a *Te Deum;* and some cantatas. In 1847 he removed to Paris, where his comic opera *Les Monténégrins* was presented at the Opéra Comique (1849), followed by *Le château de la barbe bleue* (1851) and *Yvonne* (1859), while his *Maître-chanteur* was given at the Opéra (1853) and again in Brussels (1870) under the title *Maximilien.*

LIMNAN′THEMUM. A genus of plants. See VILLARSIA.

LIMNO′RIA. See GRIBBLE.

LIMOGES, lē′mŏzh′. An episcopal city, the capital of the Department of Haute-Vienne, France, and the ancient capital of Limousin (q.v.), situated on the right bank of the Vienne, 215 miles south-southwest of Paris (Map: France, S., F 3). It is a very old town, with narrow, crooked streets in the older quarters and many buildings and monuments attesting its antiquity. The newer portions were built up after the demolition of the old fortifications. The most notable building is the cathedral of St. Etienne, begun in 1273 on the site of an older church and completed only in 1890. The interior is decorated in Renaissance style and contains a delicately ornamented rood loft of the sixteenth century and tombs of the former bishops of Limoges. There are two other churches dating respectively from the thirteenth and fifteenth centuries and the eighteenth-century bishop's palace with fine gardens. The town hall is a modern Renaissance building (1878–81) and has a collection of paintings and sculptures. Limoges has some Roman remains and a number of private houses dating from the Middle Ages. The educational institutions of the town consist of a lycée, a theological seminary, preparatory schools of medicine and pharmacy, a national school of decorative arts, a commercial and industrial school, a library of 85,000 volumes in 1913, a museum of ancient pottery, and a meteorological observatory. Every seven years it celebrates the Fête d'Ostension to commemorate the destruction in the tenth century of 40,000 persons by the plague. Limoges has since ancient times been known for its artistic industries. In the Middle Ages it was celebrated for its mint and gold ware and later for its enamels. In 1736 the porcelain industry was introduced, and, favored by the discovery of fine clays in the vicinity, it developed very rapidly. It is now one of the chief centres of the porcelain industry in Europe. About 8000 men are employed in the porcelain factories of the town, and considerable quantities of kaolin are exported to other European countries and even America. A printing establishment was founded at Limoges as early as 1496 and the printing of books is among the chief industries of the town. Other prominent industries of Limoges are distilling, brewing, tanning, and the manufacture of shoes and clogs, nails, knives, hats, gloves, paper, and machinery. The textile industry, once extensive, is now in a state of decline. Limoges is advantageously situated for commercial purposes, and carries on a considerable trade between Paris and the south of France. It is the headquarters of the Twelfth Army Corps. Pop., 1901, 77,862; 1911, 92,181. At the Roman conquest Limoges was the capital of the Gallic tribe Lemovices, and a place of considerable strength and importance. It suffered greatly from the Vandals and during the Hundred Years' War, as well as from frequent conflagrations. Christianity was introduced in the third century by St. Martial, the first Bishop of Limoges. In 1630–31 the town was ravaged by a terrible pestilence, in which over 20,000 people perished.

LIMON, lē-mōn′. The principal seaport of Costa Rica, situated on the eastern (Caribbean) coast, at the eastern terminus of the interoceanic railroad to Puntarenas (Map: Central America, F 6). It has a good harbor, well provided with wharfage facilities, is regularly visited by five lines of steamers going to American and European ports, and is the seat of a United States Consul. It exports most of the coffee produced in Costa Rica, besides tropical fruits, rubber, and dyewoods. Pop., 6539.

LI′MONITE (from Gk. λειμών, *leimōn*, marshy, meadow), or Brown Hematite. The hydrated sesquioxide of iron ($2Fe_2O_3 3H_2O$), containing 59.89 per cent of metal. When pure or nearly so, it occurs in compact masses with a silky or submetallic lustre, brown or brownish yellow in color, and a hardness of 5–5.5 on the mineral scale; but when mixed with clay, as it often is, it is found in the form of a loose ochreous earth, colored various shades of yellow or brown. The limonite of commerce may contain other hydrous iron oxides such as goethite and turgite, therefore the term *brown ore*, which would include all these, is a better one. Limonite is a commercial source of iron, but by no means the most important one. It may be found in several different forms as follows: 1. Bog ore, found in lakes and swamps, due to the precipitation of iron in the hydroxide form from spring and pond waters. This is of no commercial importance in the United States, but was worked formerly to some extent in Canada. In some countries, notably Sweden, the bog ore accumulates to a thickness of half a meter in from 15 to 30 years. 2. Gossan ore, a porous mass of hydrous iron oxide, formed by the weathering of deposits of sulphides of iron, or sometimes iron and copper. A few deposits have been worked in the Eastern States. They are common in the West, and may carry gold, silver, or even manganese. 3. Residual deposits, in which the ore forms lumps and masses scattered through residual clay. These are often associated with Cambro-Silurian formations in a belt from Vermont to Alabama, and are worked chiefly in Alabama and Virginia. 4. Replacement deposits, the ore replacing limestones and sandstones. These are best known in Virginia. The limonite is not a high-grade ore of iron, and often carries much clay and silica. The residual material is prepared for market by a washing process. The merchantable ore contains 40 to 50 per cent iron. The production of brown ore in the United States in 1913 amounted to 1,577,019 long tons.

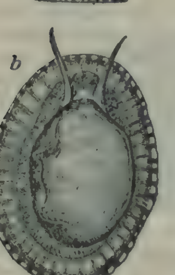
LIMOUSIN, lē′mōō′zăɴ′. An ancient province of France, now comprised in the departments of Haute-Vienne, Creuse, and Corrèze (q.v.) (Map: France, S., F 3). The land of the ancient Lemovices, it was part of the dowry of Eleanor of Aquitaine when she married Henry II of England in 1152. In the thirteenth century it passed to Brittany and subsequently to the house of Albret and was united with the French crown by Henry IV. The capital was Limoges.

LIMOUSIN, or **LIMOSIN**, lē′mō′zăɴ′, Léonard (active, 1535–74). A French enamel painter. Nothing is known positively concerning his birth and training, but he was born probably at Limoges and studied with Nardon Penicaud; he was influenced also by the German school and the Italian masters of Fontainebleau. He was appointed valet de chambre (practically court painter) to Francis I and Henry II of France, for whom he executed many portraits in enamel, besides other decorative works, such as vases, plaques, goblets, medals, dated from 1535 to 1574. Of his recorded output of 2000 enamels many fine examples survive in the Louvre, including two votive tablets (each of 23 plaques) for the Sainte Chapelle (1523). Although he occasionally worked in translucent enamels, he usually preferred a few opaque colors, generally using dark blue or green as backgrounds for his portraits, which are particularly celebrated and rival Clouet's portrait heads. Among those in the Louvre are several of Diane de Poitiers, one showing her mounted behind Henry II on a white horse. The Morgan collection, Metropolitan Museum, New York, also contains some excellent specimens, including Francis I and Margaret of Navarre and a small unknown portrait dated 1546. Other members of his family, known as workers in enamel, lived in Limoges, which was famed for this especial kind of art for several centuries. Consult the monographs by Boudery (Limoges, 1895), and Boudery and Lachenaud (Paris, 1897).

LIM′PET (probably from AS. *lempedu*, variant of *lamprede*, lamprey, from ML. *lampreda*, lamprey, from Lat. *lambere*, to lick + *petra*, rock; hardly connected with Lat. *lepas*, Gk. λεπάς, limpet, from λέπας, bare rock, from λέπειν, *lepein*, to strip, to peel). A gastropod mollusk of the prosobranchiate family Patellidæ, in which the shell is nearly conical, not spiral, and with a wide mouth and the apex turned forward. The animal has a large round or oval muscular foot by which it adheres to rocks, the power of creating a vacuum being aided by a viscous secretion. Limpets live on rocky coasts, between tidemarks, and remain fixed when the tide is out, as their fringed gills cannot bear exposure to the air, but move about when the water covers them; many of them, however, it would seem, remain long on the same spot, which in soft calcareous rocks is found hollowed to their exact form. The power of adherence is very great, so that, unless surprised by sudden seizure, they are not easily removed without violence sufficient to break the shell. Curious cases of the homing instinct of limpets are reported by Morgan. If removed from their station or "home" on a rock, they will find their way back, even if carried away as far as 3 feet. They feed on algæ. The sexes are distinct. The species are numerous and exhibit many varieties of form and color. The American species is *Acmæa testudinalis* and is common along the New England coast. Some of the limpets of warmer climates have very beautiful shells. A species found on the western coast of South America has a shell a foot wide which is often used as a basin. The name is often extended to other shells, especially of the related families Acmæidæ and Fissurellidæ (keyhole limpets) and the genus *Crepidula* (slipper limpets). The fresh-water snails of the genus *Ancyclus* are called fresh-water limpets, from the shape of the shell. Limpet-like shells are found fossil in rocks of all ages from the Cambrian upward, and many of the early forms cannot readily be distinguished from modern genera. The oldest is *Scenella*, a low conic shell with reticulate surface, found in the Cambrian. *Palæacmæa*, with a smooth low conic shell, is from the Upper Cambrian. The genera *Patella* and *Acmæa* occur from the Silurian upward; *Metoptoma*, with a straight anterior margin, is a common Silurian to Carboniferous fossil, and *Tryblidium*, with a thick oval flattened shell marked by strong imbricating plates, is a curious Silurian form evidently evolved from some early limpet.



A LIMPET (*Patella*).

a, outline of shell in its natural position; *b*, underside, on a larger scale, showing the broad foot, tentacles, and gill fringes of the animal.

LIMP′KIN, or COURLAN. A bird of tropical America, representing the family Aramidæ, which is intermediate in its characteristics between the rails and the cranes. Two species are known—*Aramus scolopaceus* of eastern South America, and *Aramus pictus*, or *vociferus*, of Central America, the West Indies, and southern Florida. The Spanish people of that region call it "viuda loca" (mad widow) on account of "its sombre plumage, solitary habits, and peculiar cry," which is heard at night in a melancholy wail. It is a bird of the swamps, flies heavily and awkwardly, and feeds on frogs, aquatic insects, etc. See Plate of CRANES, ETC.

LIMPO′PO, UBI, or CROCODILE. A river in the eastern part of South Africa (Map: Cape of Good Hope, J 4). It rises a little west of Pretoria in the Province of Transvaal and after a short course towards the northwest is joined by the Marico and forms from the point of junction the boundary line separating the Province of Transvaal from the Bechuanaland Protectorate and Southern Rhodesia. After it leaves British territory it flows in a southeastern course through Portuguese East Africa and enters the Indian Ocean through Delagoa Bay. Its total length is about 1000 miles. In its upper course it flows through an elevated region and forms a number of rapids, while the portion in Portuguese territory is chiefly through lowlands. The most important tributary is the Olifant. The Limpopo is navigable for about 100 miles from its mouth during all seasons and farther during flood seasons; but its mouth is obstructed by sand bars, and the river is not important for commerce.

LIMU, lē′mo͞o. A kind of edible seaweed used in Hawaii. See CARRAGEEN.

LIM′ULUS. See KING CRAB; MEROSTOMATA.

LINACRE, lĭn′ȧ-kēr, or **LYNAKER**, THOMAS (?1460–1524). An English humanist, physician, and divine, born at Canterbury. He studied at Oxford and became fellow of All Souls' College in 1484. Shortly afterward he went to Italy and devoted himself to the study of Latin, Greek, natural philosophy, and medicine under the famous teachers of the day, and translated some of Galen's treatises. Returning to England, he received the degree of D.D. and the appointment of professor of physic from Oxford University; was called to the court by Henry VII and made physician and tutor to Prince Arthur; was subsequently physician to Henry VII, Henry VIII, and Princess Mary. Later in life he gave up practice, took orders, and was made in 1509 rector of Mersham and prebend of Wells; in 1518 prebend and in 1519 precentor in York Cathedral. His most celebrated works are his Latin translations from Galen, among which are: *De Temperamentis* (1521); *De Tuenda Sanitate* (1517); *De Methodo Me-*

dendi (1519). His other works are a translation of *Proclus de Sphæra; De Emendata Structura Latini Sermonis* (1524). He was buried in St. Paul's Cathedral, where Dr. Caius erected a monument to his memory. He rendered important service in promoting the study of medicine and was instrumental in founding the College of Physicians (1518), of which he was the first president. But his main title to remembrance rests upon scholarship and his connection with Erasmus and the other learned men who fostered classical learning in England. With Grocyn and Latimer he was among the first to teach Greek at Oxford, where Erasmus and Sir Thomas More were among his pupils. Consult his *Life* by J. N. Johnson, ed. by Robert Graves (London, 1835).

LINARES, lê-nä′râs. A province of Chile, bounded by the Province of Talca on the north, the Republic of Argentina on the east, the Province of Nuble on the south, and Maule on the west. Area, 3942 square miles (Map: Chile, E 5). It is mountainous and well wooded, and has extensive tracts of grazing land. The chief occupations are stock raising and viticulture. The province is traversed through the centre by the main railway line of Chile. Pop., 1895, 101,858; 1911, 112,566. The capital of the province is Linares (q.v.).

LINARES. A capital of the province of the same name in Chile (Map: Chile, E 5). It lies on a plain, 55 miles from the Pacific coast and 85 miles northeast of Concepción. It is an important commercial centre and station on the railroad running south from Santiago. Pop., 1895, 7331; 1907, 11,122.

LINARES. A city of Spain, in the Province of Jaén, 24 miles north of Jaén, on a branch of the railroad between Córdoba and Madrid (Map: Spain, D 3). It is an important mining town, the mines in the neighborhood producing annually 80,000 tons of argentiferous lead and copper ores. These mines were exploited under the Carthaginians and the Romans, but were afterward abandoned until the eighteenth century. In 1891 an elaborate plant for the extraction of the metals was built here and is considered one of the best in Europe. Besides this the town has lead and iron foundries and manufactories of powder, dynamite, and rope. Pop., 1887, 29,692; 1900, 38,245; 1910, 36,419.

LINARES, DUKES OF. FERNANDO DE NOROÑA, chamberlain of Philip IV, fifth Count of Linares, created Duke of Linares, was succeeded (1659) by his son MIGUEL, second Duke, who in turn was succeeded by his brother JOSÉ ANTONIO, third Duke. The latter's successor, his sister JUANA, fourth Duchess, married the Duke of Abrantes and united these two ducal titles.

LINARES, JOSÉ MARÍA (1810–61). A Bolivian statesman, born in Potosí. He studied law and after his admission to the bar began to take an active part in public life, becoming a member of the commission appointed to codify the laws of Bolivia. In 1839 he was made Minister of the Interior, and he was afterward Minister to Spain, where he negotiated the treaty whereby Spain recognized the independence of Bolivia. In 1848 he was President of the Senate and in 1857 was elected to the presidency of the republic. He endeavored to carry out a policy of reform and economy, but was prevented from so doing by a revolution which drove him from power.

L'INCARNATION, läɴ′kär′nȧ′syôɴ′, MARIE DE. A French religieuse in America. See MARY OF THE INCARNATION.

LINCEI, lên-chā′ê, ACCADEMIA DEI. A celebrated Italian learned society, founded at Rimini in 1603 by Federigo Cesi, son of the Duke of Acqua Sparta, for the purpose of fostering the study of the physical sciences. The name *lincei*, or lynxes, is supposed to have been adopted as an expression of the members' belief in the possibility of piercing the depths of scientific truth. Though it numbered among its members such men as Galileo and Stelluti, the society languished after 1630 and gradually died away. Restored in 1745 by Giovanni Branchi, it passed once more out of existence. It was revived for a second time towards the end of the eighteenth century, but was of little real importance till the occupation of Rome by the Italian troops in 1870, when it became what it has remained to the present day, one of the principal associations in Italy for the advancement of science and scholarship. As reorganized in 1870, it is divided into a royal and a papal section.

LINCOLN, lĭŋ′kon. The capital of Lincolnshire, England, a civic county, parliamentary, and municipal borough, and episcopal see, on the Witham, 130 miles northwest of London (Map: England, F 3). It is a junction of six railroads and has extensive canal communications.

Built on the slope of a hill, which is crowned by the cathedral, the city is imposing. It is irregularly laid out and contains many interesting specimens of early architecture, such as the Roman Gate (dating from about 104 B.C., now known as the Newport Arch), the remains of the Norman castle and of the palace and stables of John of Gaunt, the famous Jews' House (one of the earliest specimens of domestic architecture extant in England), and the town hall. The cathedral, commonly called the minster, one of the finest in England, is the principal building. It is surmounted by three towers, two of which, 180 feet in height, were formerly continued by spires of 101 feet. The central tower, 53 feet square, is 300 feet high. The interior length of the cathedral is 482 feet, the width 80 feet. The finest feature of the minster is the presbytery, or Angel Choir, dating from 1255, which has been described as "one of the loveliest of human works." The famous bell called Tom of Lincoln, cast in 1610 and recast in 1834, hangs in the central tower; it is 5 tons, 8 hundredweight in weight. The style of the cathedral is chiefly early English. The old church of St. Peter-at-Gowts is remarkable for its well-preserved pre-Norman tower. Lincoln has numerous schools and benevolent institutions. Its municipal administration is noteworthy. It owns remunerative real-estate markets, a race course, water works, and gas and electric-lighting plants, and maintains a free library, technical schools, an arboretum, recreation grounds, public baths, and a sewage farm. One member is returned to the House of Commons for the city. Several iron foundries and manufactories of portable steam engines and agricultural machines, as well as large steam flour mills, are in operation here, and there is an active trade in corn and wool. Lincoln is an important livestock market, and horse and cattle fairs are annually held. It is also an important horse-racing centre. The town was called by the Romans Lindum, which, with Colonia, gives the modern name. Lincoln under the Romans was a place of some importance and also under the Saxons and Danes. It

LINCOLN CATHEDRAL

was the seat of an extensive shipping trade at the time of the Norman Conquest, the river at that time being navigable for large vessels. Pop., 1901, 48,784; 1911, 57,294. Consult: Allen, *History of Lincoln* (London, 1833); A. F. Kendrick, *Cathedral Church of Lincoln: A History and Description of its Fabric and a List of the Bishops*, in "Bell's Cathedral Series" (ib., 1898).

LINCOLN. A city and the county seat of Logan Co., Ill., 29 miles northeast of Springfield, on the Chicago and Alton and the Illinois Central railroads (Map: Illinois, F 5). It is the seat of Lincoln University (Cumberland First Presbyterian), opened in 1865 and affiliated with Milliken University, and of the State School and Colony for Feeble-Minded Children. It has also a Carnegie library, Odd Fellows Orphans Home, St. Clara's Hospital, and Deaconess Home and Hospital. In the old courthouse here Lincoln practiced as a lawyer. Among the city's industrial plants are coal mines, extensive greenhouses, flour mills, creameries, and manufactories of electric automobile signal horns, shoes, corn-cutting machinery, furniture, mattresses, caskets, etc. Lincoln was incorporated in 1854 and in 1915 adopted the commission form of government providing for one mayor and four commissioners elected quadrennially. Pop., 1900, 8962; 1910, 10,892; 1914 (U. S. est.), 11,532; 1920, 11,882. The city was named in honor of Abraham Lincoln, who assisted in laying it out.

LINCOLN. A city and the county seat of Lincoln Co., Kans., about 153 miles by rail west of Topeka, on the Saline River and on the Union Pacific Railroad (Map: Kansas, D 4). It contains a Carnegie library. The city carries on a considerable trade in grain, produce, live stock, etc., and has grain elevators and flour mills, and extensive quarries of fine limestone. It owns its water works and electric-light plant. Pop., 1900, 1262; 1910, 1508.

LINCOLN. The second city of Nebraska, State capital and the county seat of Lancaster County, 55 miles southwest of Omaha, on the Burlington Route, the Chicago, Rock Island, and Pacific, the Chicago and Northwestern, the Union Pacific, and the Missouri Pacific railroads (Map: Nebraska, H 4). The attractive city, with wide avenues and modern business blocks and homes, lies on a slightly rolling prairie. It is the seat of the University of Nebraska (see NEBRASKA, UNIVERSITY OF), Nebraska Wesleyan University (Methodist Episcopal), Cotner University (Disciples of Christ), Union College (Adventist). The State Asylum for the Insane and the State Penitentiary are located here. The noteworthy buildings include, besides those already indicated, the State capitol, built of white limestone at a cost of $500,000, United States government buildings, county courthouse, St. Elizabeth's Hospital, the Home for the Friendless, and the public library, costing $75,000, the gift of Andrew Carnegie. There are also the State, State Historical, and State University libraries.

The central position of the city and its railroad facilities make it an important distributing point for the agricultural and mechanical productions of a large area. There are numerous grain elevators, the city being the centre of an important grain and milling trade, and manufactories of gasoline engines, corsets, paint, upholstered goods, mattresses, brooms, dusters, overalls and shirts, saddles and harness, sashes and doors, flour, bricks, creamery products, etc. The commission form of government was adopted in May, 1913, and provides for a council of five members and a mayor, elected every two years. The city clerk, attorney, engineer, superintendent of the water and light department, and the library board are appointed by the council. The police judge is chosen by popular election. The water works and electric-light plant are owned and operated by the municipality. Lincoln spent in 1912 for maintenance and operation $484,103, the main items being $261,063 for education, $56,029 for the water works, $55,719 for the fire department, and $21,469 for the police department. Pop., 1870, 2441; 1890, 55,154; 1900, 40,169; 1910, 43,973; 1914, 45,643; 1920, 54,934.

In 1859 the site of Lincoln was chosen for the location of a city to be called Lancaster, but there were hardly a dozen settlers there in 1864, when the place was laid out. Three years later, the inhabitants then numbering less than 30, Lancaster was chosen as the capital of Nebraska, and its name changed to Lincoln in honor of Abraham Lincoln. It is the home of William Jennings Bryan. Consult Hayes and Cox, *History of the City of Lincoln* (Lincoln, 1889).

LINCOLN. A town in Providence Co., R. I., 3 miles northwest of Pawtucket, on the Blackstone River. Its most noteworthy feature is Lincoln Reservation, a beautiful park. The manufacture, dyeing, and bleaching of cotton cloth constitutes the chief industry. Pop., 1900, 8937; 1910, 9825.

LINCOLN, ABRAHAM (1809–65). The sixteenth President of the United States, born near Hodgenville, in Hardin Co., Ky., Feb. 12, 1809. His ancestry has been with some difficulty traced back to Samuel Lincoln, of Norwich, England, who emigrated to America and settled in Hingham, Mass., in 1638. Some of his descendants, who were Quakers, settled in Amity Township, Berks Co., Pa., and finally in Rockingham Co., Va. The Virginia Lincolns are described as "reputable and well-to-do." One of them, the President's grandfather, removed to Jefferson Co., Ky. Thomas Lincoln, Abraham's father, was a carpenter and a farmer, illiterate and thriftless; Nancy Hanks, his mother, was of humble parentage, but possessed of a keen intellect and considerable force of character. After several removals in Kentucky Thomas Lincoln went in 1816 to Spencer Co., Indiana. At the new home his wife died after two years, when Abraham was not quite eight years old, and a year later he married Mrs. Sally (Bush) Johnson, whom he had formerly courted. All Abraham's schooling combined would probably not have made up more than one year. As he grew up, however, he had a few books which he read and reread—the Bible, Shakespeare, Æsop's *Fables*, *Robinson Crusoe*, *Pilgrim's Progress*, a history of the United States, and Weems's *Washington*, and he borrowed some others from his neighbors. He seems to have been ambitious from the outset, trying hard to learn, but much influenced by the coarseness of his surroundings, from the externals of which he never got quite free. He grew to be 6 feet, 4 inches in height; marvelous tales are told of his strength, and much more credible ones of his skill at jesting, story-telling, and popularity.

When Abraham was 21, his father's migratory nature impelled him to try his fortunes in Illinois, and he settled on the north fork of the Sangamon, which empties into the Illinois.

Here the younger Lincoln helped to split rails and to clear and plant some 15 acres. In 1831, with two relatives, he took a flatboat to New Orleans, whither he had made a previous trip. Ten years later he went to New Orleans again. These trips enabled him to see something of the nature of slavery. In 1832 Lincoln was chosen captain of a company of volunteers for service in the Black Hawk War. They saw no fighting and were mustered out within five weeks, when Lincoln reënlisted as a private, serving until June 16. He then returned to Sangamon, making his abode at the little mushroom town of New Salem, and, having announced his candidacy for the State Legislature, he began electioneering vigorously. With great humor and with an energy not always confining itself to strict argument, he advocated pure Whig doctrine—a national bank, internal improvements, and a protective tariff. The follower of Clay was beaten by the Jacksonian Democrats, but he had gained experience and had spread his popularity. His next venture was as a partner in a dry-goods and grocery store at New Salem; but the concern failed, the partner fled, and Lincoln was left to settle the losses. He paid all he owed in 1849. Having no gift for trade, he now began to read law, studied hard, and made swift headway. In May, 1833, he was appointed postmaster at New Salem and is said to "have carried the post-office in his hat," for the mail came but once a week. This position he held three years; at this time, too, he was a deputy county surveyor. In 1834 Lincoln's personal property was about to be sold by the sheriff to satisfy a judgment, when a new friend, Bolin Greene, bid in the property and gave it over to him. In 1834 he was again a candidate for the Legislature and was elected, running far ahead of his ticket. He was rather an observer than an active legislator in this session.

Lincoln's first love was unhappy. While boarding with James Rutledge, in New Salem, he became enamored of Ann, his landlord's daughter, a well-reared girl of 17. She had at the time another lover, who promised marriage, but he broke his word. Lincoln and Ann Rutledge were betrothed in 1835, but the girl fell ill, and in August she died of brain fever.

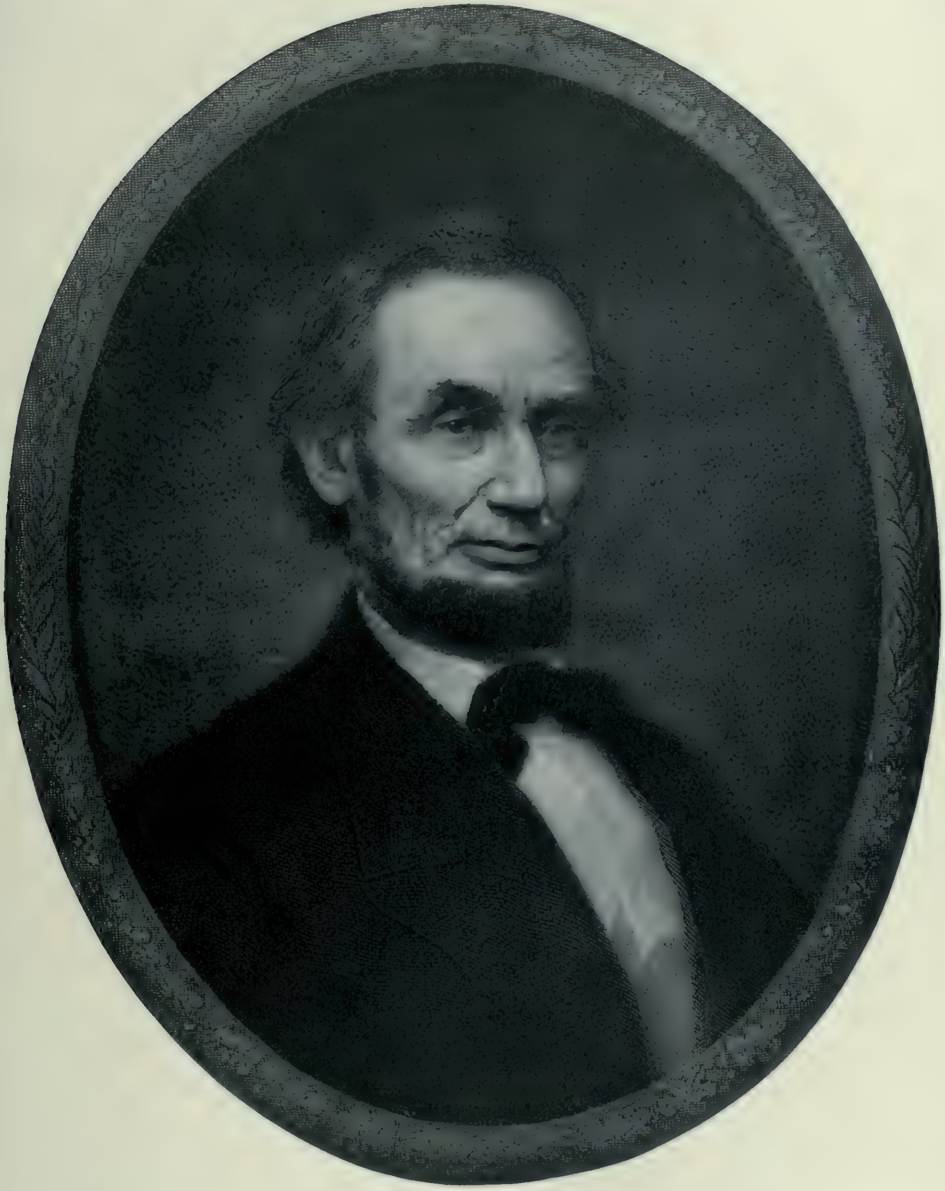
In 1836 Lincoln was again a candidate for the Legislature on the following characteristic platform: "I go for all sharing the privilege of the government who assist in bearing its burdens. Consequently, I go for admitting all whites to the rights of suffrage who pay taxes or bear arms, by no means excluding females." Lincoln stumped the district and by his vigorous speeches won a Whig victory. In the presidential contest of 1836 Lincoln was for Hugh L. White, of Tennessee. In the struggle of Jackson against the United States Bank and the shifting policy of Van Buren he had no interest, but he heeded his duties as a legislator and began that antislavery record upon which so much of his fame will ever rest. The Abolitionists were in the highest activity. Garrison's *Liberator* was intensely annoying to the upholders of slavery. President Jackson had at the close of 1835 invited the attention of Congress to the circulation through the mails of what were then called "inflammatory" documents. Henry Clay, Edward Everett, many of the governors of the Northern States, and a large majority of the House of Representatives strenuously opposed the agitation of the slavery question; all petitions to Congress on the subject were laid on the table without reading or debate, and all possible means were taken to prevent the discussion of the hateful subject. On the night of Nov. 7, 1837, the Rev. Elijah P. Lovejoy was mobbed and shot dead at Alton, Ill., for persisting in publishing an Abolition newspaper.

At this juncture, when the Legislature was about to pass resolutions deprecating the antislavery agitation, Lincoln presented his protest, to which he could get but one signer besides himself. Herein he declares slavery to be founded on injustice and bad policy; but he avers that Abolition agitation tends to increase slavery's evils; that Congress may not interfere with slavery in the States, though it might in the District of Columbia on the request of the people. This protest was meant to avoid extreme views; therefore no mention was made of slavery in the Territories, that point being covered by the Missouri Compromise, which was then in full force. Lincoln was never extreme, and probably till the war began he saw no hour when he would have altered a word in this protest.

When the State capital was removed to Springfield in 1839, Lincoln settled there. Two years before he had been licensed as an attorney, and, being at the capital, he could attend both to his duties as a member of the Legislature and his law practice. His business grew so rapidly that he took into partnership John T. Stuart, a prominent Whig, who had been a good friend also in former years. Lincoln preferred to be the junior in the firm. Springfield was a village of about 1500 inhabitants, and Lincoln was not only poor, but he was in debt.

In 1840 Lincoln was an elector on the Harrison ticket and made speeches in all parts of the State. But one-sided speeches were not suited to his temper; he preferred joint debates, wherein he might employ his masterly skill at retort. A year earlier Lincoln had made the acquaintance of Mary, the daughter of the Hon. Robert S. Todd, of Lexington, Ky., and a sister of the wife of Ninian W. Edwards, of Springfield, a distinguished lawyer. Through her comeliness and her wit the young lady had gained many admirers. Some political papers were contributed by her to a local newspaper; and Lincoln, to shield her, assumed the responsibility, barely avoiding a duel. About six weeks afterward, Nov. 4, 1842, he married Miss Todd.

In 1844 Lincoln was once more an elector on the Clay (Whig) ticket, and in 1846 he was elected to Congress by 1511 majority in a district which two years before had given him only 914. When he took his seat as Representative in the Thirtieth Congress, his great rival, Stephen A. Douglas, was in the Senate. Lincoln was put on the Committee of Post Offices and Post Roads. Though opposed to the Mexican War, he voted for supplies to carry it on. He supported the principle of the Wilmot Proviso and introduced a bill providing for the emancipation of slaves in the District of Columbia, not, however, without compensation to the owners. In 1848 he favored the nomination, by the Whigs, of Taylor for President, and made a strong speech in the House for that purpose, subsequently speaking in various parts of the country. For several years fol-



ABRAHAM LINCOLN
AFTER THE PORTRAIT BY WILLIAM MARSHALL

lowing the expiration of his term in Congress Lincoln was not active in politics. He wished to be Commissioner of the General Land Office, but he did not get the appointment. He was offered the governorship of Oregon Territory, but his wife declined to go there, and he would not accept. In 1850 he refused a nomination for Congress.

His law partnership with Stuart ended April, 1841, when he united in practice with ex-Judge Stephen T. Logan and soon afterward formed a partnership with his best friend, William H. Herndon. As a lawyer, he spoke tellingly and often to the mirth of the court room. Many curious anecdotes are told of the great man as a story-teller, of his power, his energy, his oddities, and his generosity. Though thousands of good stories unknown to Lincoln pass current as having been told by him, it is true that few great statesmen were more capable than he of perceiving the kernel of a tale. He had also a ready and humorous wit and was quick to follow a good parry with a well-aimed thrust. His small fees and his frequent refusals to take cases in which he thought that right was with the other party reflect his abhorrence of the sale of self for money.

The bill offered by Douglas, Jan. 4, 1854, to establish a Territorial government in Nebraska, reopened the antislavery war, and Lincoln was forced to take decided ground against spreading slavery into the Territories. This he did at the State Fair at Springfield, Ill., in October, in a speech of great power. Lincoln had felt that his natural opponent was Douglas, and he seized eagerly this opportunity of refuting his arguments; Douglas recognized his opponent's strength and secured from him a truce from debating for that fall. In November, despite his positive declination, Lincoln was again elected to the Legislature. At the same time he was very desirous to succeed Shields (a Democrat) in the United States Senate, and, although he did not win the election for himself, he won it for Lyman Trumbull, a fellow opponent of the Kansas-Nebraska Act. During the Kansas excitement Lincoln's sympathies were all in favor of the free-State side, but he discountenanced the use of force.

It was at the State Convention at Bloomington in 1856 that the formation of the Republican party in Illinois was consummated, and there Lincoln made one of his greatest antislavery speeches, but it is preserved only in description. On June 17, 1856, at the Republican Nominating Convention at Philadelphia, Lincoln's name was put forth for Vice President and was received with considerable favor, for he got 110 votes. This year, for the third time, Lincoln was on the electoral ticket, now as a Republican, and he made some 50 speeches for Frémont. The quality of these speeches bettered his reputation and spread it even to the East. In April, 1858, the Democrats indorsed the stand Douglas had taken in the Kansas dispute and renominated him for the Senate. Lincoln expected and received the Republican nomination in June, and in accepting he delivered the carefully thought out speech near the beginning of which was the following passage: "'A house divided against itself cannot stand.' I believe this Government cannot endure permanently half slave and half free. I do not expect the Union to be dissolved—I do not expect the house to fall—but I do expect it will cease to be divided. It will become all one thing or all the other." In July he challenged Douglas to the now famous seven debates, the direct result of which was to win the latter the senatorship. Lincoln, however, was not arguing for the senatorial prize alone, but with a greater purpose—he was fighting for Republican success in the presidential contest of 1860, and the opportunity it would bring to "hit hard" the great "moral, social, and political wrong" of slavery.

In April, 1859, the people of his own town began to talk of Lincoln as a proper candidate for President, but he discouraged the idea. In September he made speeches in Ohio in the track of Douglas; in December he spoke at several places in Kansas. He was more and more talked of for a presidential nomination and finally authorized his friends to work for him. On Feb. 27, 1860, on invitation, he appeared in New York and spoke in Cooper Institute. The address was warmly praised in most of the city journals and was in fact highly successful. After this he spoke in many cities in New England. He was present, though not a delegate, at the Illinois State Convention (May 9, 1860), where he received the most flattering evidences of his great popularity, which was fully assured by the adoption without dissent of a resolution declaring him the choice of the Republicans of Illinois for President.

On May 16, 1860, the Republican National Convention met at Chicago. The city was full of political workers. Indeed, no previous convention had had half the number of "outside delegates." Two days were spent in organization and the adoption of a platform. Balloting came on the third day. Up to the previous evening Seward's nomination seemed certain; but the outside pressure for Lincoln was powerful, for his friends were chiefly men of Illinois, and the convention was held in their State. On the third ballot Lincoln won the nomination, and in the afternoon Hannibal Hamlin, of Maine, was nominated for Vice President. The platform adopted, though denying the right of Congress to interfere with slavery in the States, demanded that slavery be forbidden in the Territories. It declared in favor of internal improvements and protection.

The Democratic National Convention at Charleston split on the slavery question. The South, remembering Douglas's admission in debate with Lincoln that "slavery cannot exist a day or an hour anywhere unless it is supported by local police regulations," totally repudiated him and his squatter sovereignty, whereas Douglas was equally determined to stick to it. Most of the Southern delegates withdrew and organized a separate convention. Those who remained voted 57 times for a candidate, Douglas always having the highest number, but not the two-thirds required by Democratic precedent. They adjourned to meet at Baltimore, June 18. The seceders adjourned to meet at Richmond, Va., early in June, but after convening they further adjourned to meet June 28 in Baltimore. The result finally was the nomination of three presidential candidates: Douglas by one convention, Breckenridge, of Kentucky, by the seceders, or extreme Southerners, and Bell (formerly a Whig), of Tennessee, by the Constitutional Union party, composed for the most part of Know-Nothings and old-time Whigs. The canvass was warm on all sides. Lincoln was elected on November 6 by 180 votes, Breckenridge receiving 72, Bell 39, and Douglas 12. The election was strictly sectional, for the Republicans got no electoral vote in a Southern State. Feeling the need of all possible support, Lincoln chose his cabinet carefully, trying to get a varied representation; he wished even to have a Southerner, until his offer to Mr. Graham, of North Carolina, was flatly refused. Meanwhile the South was making ready to secede, and on December 20 the South Carolina Convention unanimously adopted the Ordinance of Secession. The year closed in gloom, and 1861 opened with no hope of peace. On February 4 a peace congress met in Philadelphia; on the same day delegates met at Montgomery, Ala., to form a Southern Confederacy; on the 18th the work was done, and Jefferson Davis was inaugurated President.

On Feb. 11, 1861, Lincoln set out for Washington, taking a rather roundabout road. Everywhere the people were eager to see and hear him. On Monday, March 4, he was inaugurated and delivered an elaborate address, full of the best qualities of his nature. The appearance of the new President is thus described by Ward Lamon, in his *Life of Abraham Lincoln:* "He was about 6 feet, 4 inches high, the length of his legs being out of all proportion to that of his body. When he sat down on a chair, he seemed no taller than an average man, measuring from the chair to the crown of his head; but his knees rose high in front. . . . He weighed about 180 pounds, but he was thin through the breast, narrow across the shoulders, and had the general appearance of a consumptive subject. Standing up, he stooped slightly forward; sitting down, he usually crossed his long legs or threw them over the arms of the chair as the most convenient mode of disposing of them. His 'head was long, and tall from the base of the brain and the eyebrow'; his forehead high and narrow, inclining backward as it rose. . . . The size of his hat was seven and an eighth. His ears were large, standing out almost at right angles from his head; his cheek bones high and prominent; his eyebrows heavy, and jutting forward over small sunken blue eyes; his nose long, large, and blunt, the tip of it rather ruddy, and slightly awry towards the right-hand side; his chin, projecting far and sharp, curved upward to meet a thick lower lip which hung downward; his cheeks were flabby, and the loose skin fell in wrinkles, or folds; there was a large mole on his right cheek, and an uncommonly prominent Adam's apple on his throat; his hair was dark brown in color, stiff, unkempt, and as yet showing little or no sign of advancing age or trouble; his complexion was very dark, his skin yellow, shriveled, and 'leathery.' . . . His countenance was haggard and careworn, exhibiting all the marks of protracted suffering. Every feature of the man—the hollow eyes, with the dark rings beneath; the long, sallow, cadaverous face, intersected by those peculiar deep lines; his whole air; his walk; his long, silent reveries, broken only at intervals by sudden and startling exclamations, as if to confound an observer who might suspect the nature of his thoughts—showed that he was a man of sorrows—not sorrows of to-day or yesterday, but long treasured and deep—bearing with him a continual sense of weariness and pain." Yet this strangely sorrowful man dearly loved jokes, puns, and comical stories, and was himself world-famous for his inimitable narrative powers.

At his inauguration Lincoln denied the right of any State or number of States to go out of the Union. In the South the address was regarded as practically a declaration of war, and preparations were hurried; in the North it was strongly approved, and parties were quickly consolidated. Less than six weeks afterward General Beauregard, on behalf of the Confederate government, bombarded Fort Sumter in Charleston harbor, forcing the surrender of Major Anderson and his small force on April 14. There began the Civil War, and from that day to the day of his death the political biography of Lincoln is nearly identical with the history of the United States. On April 15 he called for 75,000 volunteers, and hundreds of thousands in the first flush of patriotic feeling thronged to enlist. At the same time Lincoln called for a special session of Congress to meet on the Fourth of July. On April 19 he proclaimed a blockade of the Southern ports; on April 27 he authorized the suspension of the writ of habeas corpus. The date for the meeting of Congress had been made distant, to allow the President to develop his policy and to avoid the turmoil that would ensue if the members met in the height of passion. The only direct request made was for 400,000 men and $400,000,000. The request was granted with additions. On July 15 a Democratic member (McClernand, of Illinois) offered a resolution pledging the House to vote any amount of money and any number of men necessary to put down the rebellion and restore the authority of the government. There were only five opposing votes in a House of nearly 300 members.

On July 21 the Union forces were badly defeated at Bull Run and driven in a panic back upon Washington. For a moment this flight had the effect of disheartening the President. General Scott, who was commander in chief when the war broke out, resigned at the end of October, 1861, and Gen. George B. McClellan took his place. McClellan was a skillful tactician and organizer, but slow to strike. Lincoln realized the necessity for acting, but he had not yet gained the knowledge of war that he later acquired. His appointment of Edwin M. Stanton, a man not pleasing to him personally, as Secretary of War (Jan. 14, 1862), was an evidence of great statesmanship, and Lincoln had trials that would have broken a weaker man. McClellan, after waiting and complaining unnecessarily, finally began a campaign in which he was thoroughly baffled by General Lee. In July Halleck was appointed general in chief of the armies of the United States. At the end of August the principal Federal force, under the command of Pope, was defeated in the second battle of Bull Run. On September 16–17 McClellan met Lee in the bloody battle of Antietam in Maryland. This engagement was hardly decisive, but, as the Confederates were forced to give up their invasion, Lincoln chose this moment to issue his proclamation, Sept. 22, 1862, declaring that he would, on Jan. 1, 1863, emancipate the slaves of all the States then or thereafter in rebellion. This proclamation was a military measure, justified as depriving the South to some extent of an advantage it enjoyed. Politically it was of the utmost importance, since it was the means of winning from the antislavery element throughout the North a more hearty support than had previously been accorded and added greatly to the influence of the national government abroad, where economic hardships threatened to conceal the fact that the war was being fought largely to vindicate a great moral principle. The support it received finally showed Lincoln to be right. Before this, though desiring emancipation, he had labored to persuade the Border States to take the step of their own accord, in return for compensation, but he had been unsuccessful. Two years afterward Lincoln said of the proclamation: "As affairs have turned, it is the central act of my administration, and the great event of the nineteenth century." McClellan failed to use his great force to follow Lee after Antietam; Burnside took command and was defeated at Fredericksburg; Hooker was appointed and suffered the disaster of Chancellorsville. Then the tide began to turn. On July 3, 1863, Meade at Gettysburg beat off the second invasion of Lee and won a decisive victory, and on the following day General Grant captured Vicksburg. On Nov. 19, 1863, Lincoln made his immortal speech on the dedication of the National Cemetery at Gettysburg. Meade having failed to follow up his victory over Lee, Lincoln, in March, 1864, complying with the recommendation of Congress, appointed Grant commander in chief. The South was nearly worn out, and Lee's superior generalship could not prevail against Grant's determination and vastly greater resources. On April 9, 1865, Lee surrendered at Appomattox.

On Nov. 8, 1864, Lincoln was reëlected over General McClellan by a vote of 212 to 21; Andrew Johnson was elected Vice President. When Lee's surrender ended the war, Lincoln was busy with plans for reconstruction; but on April 14, 1865, before he could do anything towards utilizing his wisdom in reorganization, he was shot in his box at Ford's Theatre by John Wilkes Booth, a dissipated and fanatical actor. The ball entered Lincoln's brain, and he never regained consciousness. At seven o'clock on the following morning he was dead.

The loss to the country by this death was incalculable, and the assassin injured most of all the people he would have served. The problem of bringing the two sections again into a union which should be more than one of force was as difficult as that of managing the war. To this problem Lincoln would have brought not only his experience, but generosity, utter lack of vindictiveness, incomparable tact, a tried strength which prevented vacillation. Lincoln's most marked characteristic was the accuracy with which he understood the American people. He was wholly honest; he thought fairly and never as a bigoted partisan. As a lawyer, he was weak unless convinced of inherent right in his case, and when he was convinced he relied for victory on a skill in presenting facts which often set the other side in a light clearer than their attorneys could throw on their case. As to what was his religious creed, opinions seem to diverge almost as widely as they do concerning the Bible itself. He conquered by the power of truth. This love for truth, his infinite patience, and his hard thinking seem to have guided him unerringly in every great problem he had to solve. He who had grown up in a drifting, almost illiterate, shiftless society, who had no education save that which he had been able to pick up in hours not devoted to bread getting, directed a foreign policy of dignity, strength, and honesty. Lincoln came of rough, shiftless, poverty-stricken stock, but through inexplicable gifts he wielded in a democracy and with the full consent of the people a power as great as that of the Czar. It was altogether fitting that a man of such charity should have the honor of doing most, not only to save the Union in time of its greatest danger, but also to free his country of slavery. This was his great achievement, but events so great as the formation of the Union Pacific Railroad Company and the inception of the present national banking system also belong to his administration. Some measures taken to repress Northern sympathizers with the South brought upon him harsh criticism. In spite of this the memory of the great President is year by year held in more honor throughout the Union, and the centenary of his birth was celebrated, in February, 1909, with a deeper interest than any other similar event in the nation's history.

Bibliography. Lincoln literature is sufficient of itself to constitute an excellent small library. The standard collection of his *Writings* is that edited by his private secretaries, J. G. Nicolay and John Hay (12 vols., New York, 1905); there is also the "Federal Edition," edited by A. B. Lapsley (8 vols., ib., 1905–06); another, edited by J. H. Clifford and M. M. Miller (8 vols., ib., 1908); and the *Lincoln-Douglas Debates*, edited by E. E. Sparks (Springfield, Ill., 1908). Among the most useful general biographies are: W. H. Lamon, *The Life of Abraham Lincoln from his Birth to his Inauguration as President* (Boston, 1872); W. O. Stoddard, *Abraham Lincoln: The True Story of a Great Life* (New York, 1884); I. N. Arnold, *The Life of Abraham Lincoln* (Chicago, 1885); Nicolay and Hay, *Abraham Lincoln: A History* (10 vols., New York, 1890); Herndon and Weik, *Abraham Lincoln: The True Story of a Great Life* (2 vols., ib., 1892); C. C. Coffin, *Abraham Lincoln* (ib., 1893); J. T. Morse, *Abraham Lincoln* (2 vols., Boston, 1898), in the "American Statesmen Series"; Norman Hapgood, *Abraham Lincoln, the Man of the People* (New York, 1899); I. M. Tarbell, *The Life of Abraham Lincoln* (2 vols., ib., 1900); W. M. Thayer, *Abraham Lincoln, the Pioneer Boy, and how he Became President* (15th ed., London, 1902); W. E. Curtis, *The True Abraham Lincoln* (Philadelphia, 1903); J. G. Nicolay, *A Short Life of Abraham Lincoln* (New York, 1904); Helen Nicolay, *The Boys' Life of Abraham Lincoln* (ib., 1906); James Morgan, *Abraham Lincoln, the Boy and the Man* (ib., 1908); D. J. Snider, *Abraham Lincoln* (St. Louis, 1908). For essays, special studies, and reminiscences consult: F. B. Carpenter, *The Inner Life of Abraham Lincoln: Six Months at the White House* (New York, 1867); Gideon Welles, *Lincoln and Seward* (ib., 1874); L. E. Hosmer, *The Appeal to Arms and Outcome of the Civil War* (ib., 1907); J. F. Rhodes, *History of the United States from the Compromise of 1850* (7 vols., ib., 1910–12).

LINCOLN, Benjamin (1733–1810). An American soldier, prominent in the Revolutionary War. He was born at Hingham, Mass., Jan. 24, 1733, received a common-school education, and was engaged in farming at Hingham until 1774, acting successively as local magistrate, Representative in the Massachusetts Legislature, and colonel of militia. In 1775 he took an active part in organizing the Continental forces, and in 1776 was appointed major general of the Massachusetts militia. At the siege of Boston Washington put him in command of an expedition to force the British fleet out of Boston harbor. He commanded the Massachusetts militia at the battle of White Plains, reënforced Washington by a fresh levy of Massachusetts militia at Morristown, N. J., in February, 1777, and at Washington's request was made a major general in the Continental army on February 19 of that year. He served with marked efficiency in the Burgoyne campaign, both under Schuyler and Gates, being second in command under the latter; and on Oct. 8, 1777, received a wound which maimed him for life and caused his temporary withdrawal from the army. Resuming service in August, 1778, he was assigned to the command of the Southern army in September and arrived at Charleston, December 4. A detachment of his army was defeated at Brier Creek (q.v.) in March, 1779, and his main force met with a severe repulse at Stono Ferry in June. Later he acted in conjunction with the French under D'Estaing against Savannah, but, the combined forces meeting with a sanguinary repulse on October 9, he returned to Charleston, where he was soon besieged by the English under Sir Henry Clinton and was forced to surrender (May 12, 1780), after which he returned to Hingham, Mass., on parole. Exchanged in the spring of 1781, he joined Washington and was chosen by him at Yorktown to receive the sword of Lord Cornwallis. He held the office of Secretary of War in 1781–83 and retired to his farm at Hingham in 1784. In 1786–87 he commanded the Massachusetts militia against Shays and his followers. (See Shays's Rebellion.) He was elected Lieutenant Governor of Massachusetts in 1787, was a member of the State convention that ratified the Constitution of the United States, was one of the commissioners to treat with the Creek Indians in 1789 and with the Indians north of the Ohio at Sandusky in 1793. In 1789 he was made collector of the port of Boston, which position he held until two years before his death. Late in life he took a great interest in science and wrote a number of scientific papers which attracted considerable attention. He was a man of simple, earnest character; and the persevering zeal and disinterestedness of his public service gave him great popularity. Consult the biography by Bowen in Jared Sparks, *Library of American Biography*, vol. xiii (2d series, Boston, 1847).

LINCOLN, John Larkin (1817–91). An American educator. He graduated at Brown University in 1836, was tutor there (1838–41), and professor of Latin from 1844 until his death. He was the editor of *Selections from Livy* (1847), the *Works of Horace* (1851), *Ovid, with Notes* (1883), and the *De Senectute of Cicero* (1887).

LINCOLN, Joseph Crosby (1870–). An American story-writer. He was born at Brewster, Mass., and was educated there and at Chelsea, Mass. In 1896–99 he was associate editor of the *League of American Wheelmen Bulletin*, Boston. He then moved to New York City and engaged in literary work. Besides short stories and verse contributed to magazines, he is author of *Cape Cod Ballads* (1902; new ed., 1910); *Cap'n Eri* (1904; 2d ed., 1909); *Partners of the Tide* (1905); *Mr. Pratt* (1906); *The "Old Home House"* (1907); *Cy Whittaker's Place* (1908; 2d ed., 1910); *Our Village* (1909); *Keziah Coffin* (1909); *The Depot Master* (1910); *Cap'n Warren's Wards* (1911, 1912); *The Woman-Haters* (1911); *The Postmaster* (1912); *The Rise of Roscoe Paine* (1912); *Mr. Pratt's Patients* (1913); *Cap'n Dan's Daughter* (1914); *Kent Knowles: "Quahaug"* (1914). Collectively these form a series of entertaining sketches of Cape Cod life, with many a shrewd bit of character drawing.

LINCOLN, Levi (1749–1820). An American political leader, born at Hingham, Mass. He graduated at Harvard in 1772, was active in the patriot cause, and wrote the series of political discussions called *Farmer's Letters,* and was clerk of the court and probate judge in Worcester County in 1775–81. In 1796 he became a member of the State House of Representatives, and in 1797 of the State Senate. In 1801 he was elected to Congress to fill a vacancy and served from February 6 to March 3, then becoming Attorney-General in Jefferson's cabinet; within the same year (March 5–May 2) he was acting Secretary of State. He was Lieutenant Governor of Massachusetts in 1807–08; was acting Governor from December, 1808, until May, 1809; and in 1811 declined an appointment as associate justice of the United States Supreme Court on account of failing eyesight.

LINCOLN, Levi (1782–1868). An American politician, born in Worcester, Mass., a son of the preceding. He graduated at Harvard in 1802, began to practice law in 1805, served in the State Constitutional Convention of 1820, and was often a member of the Legislature, serving as Speaker of the House in 1822 and as President of the Senate in 1845. He was elected Lieutenant Governor of Massachusetts in 1823, was also a judge of the State Supreme Court in 1824, and was Governor from 1825 to 1834. From 1835 to 1841 he was a member of Congress and in 1848 became the first mayor of Worcester.

LINCOLN, Paul Martyn (1870–). An American electrical engineer. He was born at Norwood, Mich., studied at Western Reserve University in 1888–89, and graduated as electrical engineer from Ohio State University in 1892. He was then employed by the Short Electric Company at Cleveland, Ohio, worked for the Westinghouse Electric and Manufacturing Company at Pittsburgh, Pa., in 1892-95, and was electrical superintendent of the Niagara Falls Power Company from 1895 to 1902. In the latter year he returned to the Westinghouse Company as engineer of their power division and later became general engineer. He was appointed professor of electrical engineering at the University of Pittsburgh in 1910. The Franklin Institute awarded him the John Scott medal in 1902 for his synchronism indicator. Lincoln served as vice president in 1909–11 and as president in 1915 of the American Institute of Electrical Engineers.

LINCOLN, Robert Todd (1843–). An American politician, son of Abraham Lincoln, born at Springfield, Ill. He graduated at Harvard in 1864 and then entered the Federal army as a captain on General Grant's staff. At the close of the Civil War he settled in Chicago and practiced law until 1881, when he entered Garfield's cabinet as Secretary of War. He was retained in this position by President Arthur and in 1884 was mentioned for the presidential candidacy, but refused to oppose Arthur in the convention. From 1889 to 1893 he was Minister of the United States to Great Britain. He was counsel for the Pullman Palace Car Company, and after the death of George M. Pullman was its president. In 1911 he resigned this office and became chairman of the board of directors.

LINCOLN COLLEGE. A college of Oxford University. It was founded in 1427, under the name of the College of St. Mary and All Saints, by Richard Fleming, Bishop of Lincoln, and a former Wiclifite, for a rector and seven fellows, for the benefit of his diocese and the fighting of the Wiclifite heresy. The college was endowed in part by the impropriating of the neighboring parish church. Fleming died shortly after the college was founded, and his work was carried on by John Frost, dean of Wells, who finished the buildings and added others. The foundation was completed by Thomas Rotherham, Bishop of Lincoln, later Archbishop of York and Lord High Chancellor, who reorganized the college under new statutes in 1479–80. By these works he earned the title of second founder. The fellows were originally masters or bachelors of arts, and their election limited to the dioceses of York, Lincoln, and Wells. In 1855 new statutes provided for a rector, 12 fellows, and 14 scholars, and the fellowships were thrown open. The establishment in 1911–12 consisted of a rector, 10 fellows, 27 scholars and exhibitioners, 2 lecturers, college officers, and 114 undergraduates in all. The patronage consists of nine benefices. Of the buildings, the Hall, built in 1437, the chapel, 1631, and the kitchen, a very ancient building, are the most interesting. Among the more distinguished members of the college may be mentioned John Wesley (fellow), Lord Crewe, Bishop Williams of Lincoln, Sir William Davenant, the poet Robert Montgomery, Mark Pattison, John Morley, and James Cotter Morison. Consult Andrew Clark, *Lincoln College* (London, 1898).

LINCOLN GREEN. A color associated with the cloths for which Lincoln, England, was once famous.

LINCOLN MEMORIAL UNIVERSITY. An institution for higher education, founded in 1897, near Cumberland Gap, Tenn. The university was established largely through the efforts of Gen. Oliver Otis Howard. It is nonsectarian. The purpose of the university is to furnish educational advantages to dwellers in the mountain regions of Tennessee and other States. The university owns about 600 acres of land, which includes a beautiful campus which was laid out by Col. George E. Waring. The principal buildings are the Carnegie Library, Avery Hall, the Conservatory of Music, the Auditorium, Norton Hall, Science Hall, Ellen M. Myers Hall, and the President's House. There are also several teachers' and students' cottages. The courses of instruction include a preparatory course, scientific course, classical course, agricultural courses, and a teacher's course. There is also a medical department, consisting of the Lincoln Memorial Hospital and a training school for nurses at Knoxville, Tenn. The Grace Nettleton Home is sustained by the Grace Nettleton foundation of Lincoln Memorial University. This home was founded by Franklin E. Nettleton as a memorial to his daughter. It has for its purpose the care and education of orphan girls. The total number of students in all departments of the university in 1914–15 was 825. Of these 706 were in the university, 86 in the Medical School, and 33 in the Nurses Training School. The library contains about 5000 volumes. The president in 1914 was George A. Hubbell, Ph.D.

LINCOLN MONUMENT. A monument in the Oak Ridge Cemetery of Springfield, Ill., marking the burial place of Abraham Lincoln. It was erected in 1874 at a cost of over $200,000 and consists of a granite structure of imposing dimensions, surmounted at a height of 120 feet by a bronze statue of the martyr President.

LIN'COLNSHIRE. A maritime county of England, the second largest in the country, bounded north by Yorkshire, east by the North Sea (Map: England, F 3). Area, 2638 square miles. The surface generally is flat, a large part protected by embankments lying below the level of the sea, and forming part of the so-called Bedford Level. The county is divided into three districts—Lindsey on the northeast, on which are the Lincoln Wolds or Chalk Hills, Kesteven on the west, and Holland on the south. The chief rivers are the Trent, Witham, Welland, and the Humber, which separates the county from Yorkshire on the north. The soil is fertile, and agriculture is in an advanced state, nine-tenths of the land being under cultivation; barley is the chief crop; stock raising is a thriving industry, and there are important fisheries. Practically no minerals are found, and the manufactures of the county are very small. Capital, Lincoln. Pop., 1901, 498,780; 1911, 563,960.

LINCOLN'S INN. One of the four great guilds or societies of lawyers in England, known as inns of court, which enjoy the exclusive power of calling persons to the bar. It derives its name from the fact that the group of buildings in London occupied by it belonged to the Earl of Lincoln in the reign of Edward II. It became an inn of court soon after his death in 1310. See Inns of Court.

LINCOLN'S INN FIELDS. A great square in London near the Courts of Justice, laid out by Inigo Jones and named from Lincoln's Inn, which stands on the east side of the square. The Royal College of Surgeons faces the square on the south and the Sloane Museum on the north. The place was formerly notorious as a resort of beggars and thieves and was the scene of a number of executions for political offenses.

LINCOLN UNIVERSITY. See James Milliken University.

LINCRUS'TA-WAL'TON (Neo-Lat., from Lat. *linum*, flax + *crusta*, crust, hard surface). An embossed wall covering, designed as a substitute for wall papers, natural woods, or plaster modeling. It was named for its inventor, Frederick Walton. The material consists of linseed oil with which is mixed wood fibre or other thickening substance such as cork, cellulose, or paper. The mixture after being treated chemically is made into sheets, which are then backed with light canvas and stamped in an ornamental pattern. It is waterproof, warm, and washable. The original color is light brown or gray, but when mounted on the wall it may be painted, bronzed, or gilt. The figures may be stamped in high relief with striking effect. Lincrusta is really a variety of linoleum (q.v.).

LIND, Jenny (Madame Goldschmidt) (1820–87). A celebrated singer, popularly known as "the Swedish Nightingale." She was born at Stockholm, of humble parentage. Her wonderful voice was first noticed by an actress, through whose influence she was afterward admitted, at the age of nine, into the Stockholm Conservatory of Music, at which place she became the pupil of Crœlius and Berg. Through the school of singing attached to the Court Theatre, she was enabled to make her début (1838) as Agathe in *Der Freischütz*, in which her success was instantaneous. In 1841 she passed a period of nine months in study with Manuel Garcia in Paris. In Berlin (1844), where she had gone to study German, she sang the rôle of Vielka in Meyerbeer's *Feldlager in Schlesien*, written specially for her. In April, 1845, she made an extensive tour throughout continental Europe, during which she met with unequaled success, her singing at the Leipzig Gewandhaus firmly establishing her reputation and securing for her an engagement for the Vienna Opera. Her first appearance in England was in 1847. From 1850 to 1852 she made a tour of the United States, which was as successful from the financial point of view as it was from the artistic. She was married in Boston in 1852 to Otto Goldschmidt, who was conducting the Bach Choir. After her return to Europe she lived for a few years at Dresden and afterward settled in London. Her last public appearance was at Düsseldorf at the festival of the Lower Rhenish Musical Society in 1870. As early as 1849 she retired from the operatic stage, devoting herself exclusively to concert singing. Possibly no other stage artist has been so popular throughout the world for her personal qualities as Jenny Lind. She was widely known for her generosity. Her voice was a soprano of bright, brilliant, thrilling, and sympathetic quality, her principal accomplishment being an unrivaled mastery of coloratura. She invariably improvised her own cadenzas, which were always in exquisite taste. She died at Malvern Wells. A bust of Jenny Lind was unveiled in Westminster Abbey in 1894. Consult: Rockstro and Holland, *Jenny Lind, the Artist* (London, 1891); Rockstro and Goldschmidt, *Jenny Lind: Her Vocal Art and Culture* (ib., 1894); C. A. Wilkens, *Jenny Lind* (Gütersloh, 1913).

LIND, John (1854–). An American public official, born at Kanna, Småland, Sweden. He came to the United States with his parents in 1868 and settled in Minnesota at Goodhue, taught school in Sibley County in 1872–73, attended the State University in 1875–76, and was admitted to the bar in 1876. He then practiced law at New Ulm and later at Minneapolis, and served as receiver in the United States Land Office at Tracy (1881–85). He was a Republican member of Congress from 1887 to 1893, but by 1896 had changed his political allegiance and become an enthusiastic advocate of free silver. In this year he was unsuccessful as Democratic candidate for Governor of Minnesota, but in 1898 he was elected. Two years later, despite the record of an efficient and progressive administration, he was defeated for reëlection. During the Spanish-American War he served as a first lieutenant in the Twelfth Minnesota Volunteers. From 1903 to 1905 he was again in Congress, where he was outspoken in his denunciation of imperialism. In August, 1913, he was appointed the Envoy and personal representative in Mexico of President Wilson, and thereafter, until the mission was abandoned in April of the next year, kept the government informed regarding the complicated situation incident to the Huerta (q.v.) régime.

LINDAU, lĭn'dou. An ancient town of Bavaria in Swabia, situated on an islet at the northeast end of Lake Constance, 1300 feet above the sea (Map: Germany, C 5). It is connected with the mainland by an old wooden bridge and a railway embankment. Its excellent harbor has two lighthouses; at the entrance is the colossal statue of a lion. The recently restored fifteenth-century Rathaus, with the museum of antiquities, and the ancient Roman tower are interesting structures. The educational institutions of Lindau include a Latin school dating from 1530, a Realschule, and the ancient town library with about 14,000 volumes, many of them rare books on the classics and medicine. There are manufactures of condensed milk and breadstuffs; extensive fisheries; and an important trade in agricultural and dairy products, iron, and wood. Pop., 1900, 5853; 1910, 6618. Lindau is believed to occupy the site of the Castrum Tiberii erected by the Romans against the Vindelicians. The city is mentioned as early as 774, and in

1274 it was a free Imperial city. It joined the Schmalkaldic League in 1531, passed in 1804 to Austria and in 1805 to Bavaria.

LINDAU, Paul (1839–1919). A German dramatist, novelist, and essayist, born at Magdeburg. He studied at Halle and Berlin. For several years he lived in Paris, where he became deeply affected by the French literary spirit. Returning to Germany in 1863, he edited the *Düsseldorfer Zeitung* for a year, then went to Berlin, and in 1866 to Elberfeld, where he edited the *Elberfelder Zeitung*. In 1869 he founded in Leipzig *Das Neue Blatt*, and in 1872 in Berlin *Die Gegenwart*, which he edited till 1881. *Nord und Süd*, founded by him in 1878, he continued to edit till 1904. From 1895 to 1899 he was director of the Court Theatre in Meiningen, then of the Berlin Theatre, and later of the Deutsches Theater of Berlin. Subsequently he became dramatic critic of the Royal Schauspielhaus. In 1883 he had visited the United States as the guest of Henry Villard for the opening of the Northern Pacific Railway and had traveled widely in the West; his letters of this period to the *National-Zeitung*, Berlin, were later collected as *Aus der neuen Welt* (1884). Lindau is author of some 60 volumes of dramas, stories, sketches, and critical or controversial pamphlets, as well as of many dramatic adaptations. From 1872 to 1886 he was perhaps the most prominent literary man in Germany, but since then his fame has waned. The feuilleton style, which he learned in Paris, did very well in its place, but when applied to the drama brought first success and then failure, for his plays are empty, though possessing some superficial brilliancy. His novels show keen observation, especially of Berlin society life, but lack all deeper poetic value. His critical papers amuse, but have little lasting worth. The more noteworthy of his critical essays are *Harmlose Briefe eines deutschen Kleinstädters* (1870), *Litterarische Rücksichtslosigkeiten* (1871), and *Dramaturgische Blätter* (1875–99). To the study of French literature he contributed essays on *Molière* (1872) and *Alfred de Musset* (1877). The more noteworthy of his novels are *Herr und Frau Bewer* (12th ed., 1909), *Spitzen* (trans. as *Lace*, 1888), and *Der Tag nach der Westen* (1886; 11th ed., 1908), which has perhaps maintained itself best. His best plays—*Maria und Magdalena* (1872), *Gräfin Lea* (1881), and *Ein Erfolg* (1875)—are noteworthy for their technique, their instinct of stage effect, and their bright and witty dialogue. Lindau's collected dramas appeared in five volumes (Berlin, 1873–88). Consult: Egmont Hadlich, *Paul Lindau als dramatischer Dichter* (Berlin, 1876); Franz Mehring, *Der Fall Lindau* (ib., 1890); Victor Klemperer, *Paul Lindau* (ib., 1909).

LINDAU, Rudolf (1829–1910). A German diplomat and novelist, brother of Paul Lindau, born Oct. 10, 1829, in Gardelegen. He was for many years in the consular and diplomatic service of Switzerland and Germany. Lindau studied in Montpellier and Paris; he contributed to the *Revue des Deux Mondes*, the *Figaro*, and the *Journal des Débats*. From 1859 to 1869 he lived in the Far East and in California. In 1864 with Charles Rickerby he founded the *Japan Times* at Yokohama. In 1869 he returned to Germany, was war correspondent in the Franco-Prussian War, and from 1872 to 1878 was employed at the German Embassy in Paris. After that he lived chiefly in Berlin. His writings in French and English prove him a thorough cosmopolitan. Although less known as a littérateur than his brother Paul, he shows greater artistic ability. Wide travel and keen observation of men and manners are obvious in his works: *Un voyage autour du Japon* (1864); *Peines perdues* (1880), short stories; *The Philosopher's Pendulum, and Other Stories* (1883); in German: *Die preussische Garde im Feldzuge, 1870–71* (1872); *Robert Ashton* (1879); *Schiffbruch* (2d ed., 1880); *Gute Gesellschaft* (2d ed., 1883); *Der Gast* (1883); *Zwei Seelen* (1888); *Martha* (1892); *Liebesheiraten* (1894); *Aus China und Japan* (1896); *Türkische Geschichten* (1891; 2d ed., 1903); *Der Fanar und Mayfair* (1898); *Zwei Reisen in der Türkei* (1899); *Ein unglückliches Volk* (1903); *Alte Geschichten* (1904). He was a pupil of Turgenev. Lindau's *Gesammelte Romane und Novellen* came out at Berlin in six volumes (1892–93). Consult Erich Schmidt, *Charakteristiken*, vol. ii (Berlin, 1901), and Heinrich Spiero, *R. Lindaus Leben und Werke* (ib., 1909).

LINDBLAD, lĭnd′blȧd, Adolf Fredrik (1801–78). A Swedish composer, born at Skenninge, near Stockholm. He went to Berlin to study music under Zelter, but in 1835 settled in Stockholm. He composed more than 200 charming songs which were made popular by his pupil, Jenny Lind. They are distinctly Swedish in melody and harmony. He also wrote an opera, *Frondörerna*, a symphony, which was given by the Leipzig Gewandhaus, and a delightful violin sonata. He died in Stockholm.

LINDE, lĭn′de, Samuel Bogumil (Gottlieb) (1771–1847). A Polish lexicographer, born at Thorn, Prussia. He studied at Leipzig, where he subsequently taught Polish, and was employed in a private library in Vienna. In 1803 he was appointed director of the lyceum of Warsaw, where he died. His *Wörterbuch der polnischen Sprache* (6 vols., Warsaw, 1807–14; 2d ed., enlarged, Lemberg, 1854–60) has retained much of its scientific value.

LINDEGREN, lĭn′d*e*-grän, Amalia (1814–91). A Swedish genre and portrait painter, born at Stockholm. She painted for several years without instruction, and then studied at the Stockholm Academy. Afterward she obtained a traveling purse and studied in Paris under Tissier and Cogniet. Still later she visited Munich and Rome. Her works are genre and portraits, usually freshly painted representations of children or family life, and she is the most popular of Swedish women painters. Her "Grandfather and Granddaughter" (1853) and "Mother and Baby" are in the Christiania Gallery, and the "Dance in a Peasant's Cottage" and portraits of Queen Louise and the Crown Princess of Denmark are in the Stockholm Museum. She was elected to the Stockholm Academy in 1856.

LINDEMAN, lĭn′d*e*-mȧn, Ludvig Mathias (1812–87). A Norwegian organist and musical theorist, born at Trondhjem of a family of musicians. At 10 he played with his father in concert, at 12 he became a church organist, and from 1839 to his death he was organist in Christiania. With a government stipend, he visited all parts of the country, collecting popular songs and melodies, and published *Ældre og nyere Norske Fjeldmelodier*, text and 1000 melodies. There followed *Melodier til Landstad's Salmebog* (1871), *Norske Folketoner*, to

Petter Dass' songs (1878), and *Norske Kjæmpevisemelodier* (1884). As Norway's foremost musical theorist and contrapuntist Lindeman worked for better singing at public worship, and in 1877 his great *Koralbog* was authorized for use in the schools and the churches. In 1871, with noted composers, he was invited to the dedication of the great organ in the Royal Albert Hall, London. On this occasion he gave many concerts. Among his own compositions are cantatas, fantasias, piano sonatas, songs for choirs, and more than 380 hymns. He was connected with many musical organizations, and with his son founded the conservatory in Christiania (1883).—The son, Peter Brynie Lindeman (1858–), organist and composer, studied with his father in Stockholm and in Dresden. He succeeded his father as director of the conservatory, published many of his works, and composed numerous works of his own.

LINDEMANN, lĭn′de-män, Ferdinand (1852–). A German mathematician, born in Hanover. He studied at Göttingen, Erlangen (where he took his degree in 1873), Munich, London, and Paris. He began teaching in Würzburg in 1877 and in the same year was made professor at Freiburg. He was called to a chair at Königsberg in 1883 and 10 years later to Munich, where he was rector in 1904–05. He is celebrated for having given the first proof that π is a transcendental number, and that therefore the circle cannot be squared (see the article Circle) by the use of the compasses and the unmarked straightedge. In 1900 he was awarded the Steiner prize. Lindemann's contributions were chiefly in the form of memoirs published in the *Proceedings* of the Royal Bavarian Academy of Sciences and of other societies. He also published *Untersuchungen über den Riemann-Roschschen Satz* (1879), edited Clebsch's *Vorlesungen über Geometrie* (1877–91; 2d ed., 1904), and translated, partly with his wife, various works of Henry Poincaré and Picard.

LINDEMANN-FROMMEL, frŏm′mel, Karl August (1819–91). A German painter and lithographer, born at Markirch, Alsace. He studied in Munich under Rottmann and under his uncle Frommel, director of the Karlsruhe Gallery. In 1845–49 he lived in Rome, thence went to London, where his water colors were much appreciated, and once more was attracted to Munich, but soon left it again for Paris, where he first began to paint in oil, and where Ingres showed especial interest in his compositions. In 1856 he settled permanently in Rome, and in 1878 was appointed professor at the Accademia di San Luca. His works are distinguished for romantic conception and lustrous coloring, and include, among many other fine views of Italian scenery: "The Cloister at Albano," in the Vienna Museum; "Gulf of La Spezia," in the Karlsruhe Gallery; "Bay of Naples"; and "The Imperial Palaces in Rome."

LINDEN, lĭn′den. A town in the Province of Hanover, Prussia. Until 1885 it was a suburb of the city of Hanover, from which it is divided by the Ihme. It has a fine town hall, a Gymnasium, and manufactures of cast iron, steel, machinery, salt, pottery, carpets, celluloid, textiles, chemicals, sugar, rubber, ultramarine, asphalt, wagons, and bricks. Pop., 1900, 50,423; 1910, 73,379.

LINDEN. Various species of the genus *Tilia*. See Lime Tree.

LINDENAU, lĭn′de-nou, Bernhard August von (1779–1854). A Saxon statesman and astronomer, born at Pohlhof, near Altenburg. He studied law and political economy at the University of Leipzig. After serving as assistant judge at the tribunal of Altenburg he was from 1804 to 1817 director of the observatory at Gotha. He traveled through most of the countries of the Continent, and after holding several minor offices was put at the head of the Saxon Ministry in 1831. During his premiership he remodeled the Saxon administration and adapted it to modern requirements. He resigned in 1843. Of his scientific publications, the following deserve mention: *Tables barométriques pour faciliter le calcul des nivellements et des mesures des hauteurs* (1809) and *Geschichte der Sternkunde im ersten Jahrzehnt des neunzehnten Jahrhunderts* (1811).

LINDEN FAMILY. A family of plants. See Tiliaceæ.

LINDENSCHMIT, lĭn′den-shmĭt, Ludwig (1809–93). A German archæologist, brother of Wilhelm Lindenschmit, the painter. He was born at Mainz and at first studied art in Munich under Cornelius, but in 1846 he took up German antiquities. In 1848, with his brother, he wrote *Das germanische Todtenlager von Selzen*, an important contribution to the subject of Germanic sepulchral mounds. In 1851 he was put in charge of the Germanic Central Museum at Mainz. His publications include *Die Alterthümer unserer heidnischen Vorzeit* (8 vols., 1858–91) and *Tracht und Bewaffnung des römischen Heeres während der Kaiserzeit* (1882).

LINDENSCHMIT, Wilhelm (the Elder) (1806–48). A German historical painter, brother of Ludwig Lindenschmit. He was born at Mainz and studied at the academies of Munich and Vienna. In 1826 he returned to Munich to assist Cornelius in his decorative work in the arcades of the royal garden, the Königsbau, and the loggia of the Old Pinakothek, and soon afterward executed in the castle of Hohenschwangau a series of fresco paintings representing episodes in Bavarian history. He also adorned the ducal castle of Landsberg in Meiningen with frescoes from the history of the house of Wettin. His work shows thorough knowledge of history and costume, but is wanting in true pictorial qualities. Among his easel pictures are the "Battle of Arminius" (1839, Karlsruhe Gallery), "Entry of Otho the Great into Augsburg after the Victory on the Lechfeld," and "Death of Duke Luitpold" (gallery at Mainz).

His son, Wilhelm the Younger (1829–95), was also an historical painter. He was born at Munich and studied in Mainz under his uncle, Ludwig Lindenschmit, then at the Academy of Munich, the Städel Institute in Frankfort, the Antwerp Academy, and finally in Paris, where he produced "The Harvest" and "Duke Alba and the Countess of Rudolstadt," now both in the Hamburg Gallery. In 1863 he settled in Munich, where he was appointed professor at the Academy in 1875 and soon attracted a large following. He belonged to the group of historical painters whose work, while historically accurate in detail, is artificial and lacking in creative force and imagination. Among his numerous compositions, some representing mythological or legendary subjects, are "The Fisherman and the Mermaid" (1868, Schack Gallery, Munich); "Ulrich von Hutten Fighting French Nobles" (1869, Leipzig Museum); "Luther's Disputation with Cardinal Cajetan at Augsburg" (Wiesbaden Gallery); "Walter Raleigh in the Tower Visited by his Family" (1873, Königsberg Museum); "Assassination of William of Orange" (1872, Vienna Museum); "Venus by the Body of Adonis" (1874, New Pinakothek, Munich); "Entry of Alaric into Rome" (1886); "The Protest of Luther" (Metropolitan Museum, New York). For the Magistrates' Room in the new city hall at Munich he executed the mural painting, "Progress of Munich under Ludwig I."

LINDENTHAL, lĭn′den-täl, Gustav (1850–). An American bridge builder, born at Brünn, Austria. He was educated at the schools of his native city and of Vienna; was engaged in railroad and bridge construction in Austria and Switzerland in 1870–74; and came to the United States in the latter year. He served as an engineer of the Centennial Exposition, Philadelphia, in 1874–77; and thereafter was a consulting engineer in Pittsburgh, Pa., and in New York City after 1890. He constructed many bridges in Pennsylvania and across the Mississippi River and elsewhere, and designed a suspension bridge across the Hudson River, New York City, not built up to 1915. While serving as commissioner of bridges for New York City under Mayor Low in 1902–03, he introduced the eyebar-chain suspension design in the Manhattan Bridge. He was a member of the board of consulting engineers for the Pennsylvania tunnels and terminals, New York City, and was also consulting engineer and architect of the three-miles-long Hell Gate Bridge across the East River, New York, which was to be completed about 1917 and which at the time of its construction had the longest steel arch in the world. (See Hell Gate; New York [City], *Intercommunication.*) The Polytechnicum, Dresden, gave Lindenthal the degree of Doctor of Engineering in 1911.

LINDERBERG, lĭn′der-bĕrg, (Peder Theodor) Fernando (1854–). A Danish Socialist, born in Copenhagen. He was educated at Vallekilde, was early a gardener in Norway, and later worked as a journalist in Copenhagen (1881). Much interested in Henry George's doctrines, he founded the Danish Workingmen's Union to further social reform and was its leader from 1889 to 1895. He wrote *Henry George og hans social Program* (1899) and *Frikonkurrencen og Socialismen* (1895), which attracted much attention and enabled him to study abroad. Upon his return he published *Karl Marx og den historiske Socialisme* (1899), and organized the Labor Bureau and Library, becoming its leader and editor of its organ, *Samfundets Krav* (1900–10). The object of this institution was the publication of information about social conditions and movements in all lands. He wrote, besides the works already mentioned: *Kristendommen og den sociale Udvikling* (3 vols., 1903–08), his principal work; *Samfundet og dets ökonomiske Udvikling* (1907); *Sociale Hoveddataer i England* (1911); *Sociale Tilstande og Bevægelser ude og hjemme* (1912); *Biskop Ketteler og Socialismen i Tyskland* (1913). His teachings approach those of the Christian Socialists.

LIN′DERMAN, Henry (1825–79). An American financier, born at Lehman, Pa. He studied medicine in New York and in 1853 removed to Philadelphia, where, after practicing his profession for a short time, he was made chief clerk of the Mint in 1855–64, and its director in 1866–69. He made a valuable report on the silver market in 1872; proposed the coinage of the trade dollar; and with Knox drew up the Coinage Act of 1873. As superintendent of the Mint he wrote annual reports, of which that of 1877, arguing for a gold standard, is best known and most important.

LIND′GREN, Waldemar (1860–). An American geologist, born at Kalmar, Sweden. He was educated in Sweden, and graduated from the School of Mines, Freiberg, Germany, in 1883. He served as geologist from 1884 to 1911 and as chief geologist in 1911–12 of the United States Geological Survey, and in the latter year he became professor of economic geology at Massachusetts Institute of Technology. He is author of a treatise on *Mineral Deposits* (1913) and of many official bulletins and reports.

LINDH, lĭnd, Anders Theodor (1833–1904). A Swedish-writing Finnish poet, born at Borgå. At first a pupil in the School of Forestry at Stockholm, he afterward studied law and became one of the magistrates of his native town. His works include two volumes of poetry (1862–75) which are very popular in Finland; two dramas of less importance, *Konung Birger och hans Bröder* (1864) and *Maria af Skottland* (1865); and a translation of Byron's *Hebrew Melodies* (1862).

LIN′DISFARNE. An island in the North Sea. See Holy Island.

LIND′LEY, John (1799–1865). An English botanist, born at Catton, near Norwich. He early devoted himself to the study of botany and in 1819 published *Observations on the Structure of Fruits*, a translation from Richard's *Analyse du Fruit*. The next year he published an original work entitled *Monographia Rosarum*. In 1822 he accepted the position of garden assistant secretary of the Horticultural Society, was promoted to assistant secretary in 1826, and in 1830, in conjunction with George Bentham, organized the first flower shows held in England. He became vice secretary of the society in 1841 and member of council and honorary secretary in 1858. He was professor of botany at the University of London for one year (1829) and then held a like chair at University College, London, until 1861. He was also lecturer in botany for the Apothecaries' Company at Chelsea (1836–53). As a lecturer he was remarkably clear and concise, attracting large audiences. It was chiefly through his enthusiasm that great popular interest was developed in England in the cultivation of plants, and as editor of the *Gardener's Chronicle* (1841–65) he exerted great influence in encouraging public exhibitions of flowers and fruits. He was an untiring writer and editor, and his botanical textbooks were long standard in England. His titles are very numerous, but probably his most significant work was *The Vegetable Kingdom* (1846), followed in importance by *Theory and Practice of Horticulture* (1842) and *Fossil Botany* (1831), with William Hutton.

LINDLEY, Nathaniel, Baron (1828–1921). An English jurist. He was born at Acton Green, Middlesex, was educated at University College, London, and was called to the bar at the Middle Temple in 1850. He was appointed queen's counsel in 1872 and judge of the Court of Common Pleas in 1875, when he was knighted. From 1881 to 1897 he was Lord Justice of Appeal, and from 1897 to 1900 Master of the Rolls. In 1900 he was made a life peer, and from then to 1905 was Lord of Appeal in Ordinary. His publications include: *Introduction to the Study of Jurisprudence* (1855); *A Treatise on the Law of Partnership* (1860; 8th ed., 1912); *A Treatise on the Law of Companies* (6th ed., 1902).

LINDLEY, William (1808–1900). An English civil engineer, born in London. In 1838 he went to the Continent to be engineer in chief of the railroad from Hamburg to Bergedorf. At Hamburg he had charge of many important engineering works, including sewerage and water works, city gas works, public baths and washhouses, and harbor improvements. He left Hamburg in 1860; became consulting engineer of Frankfort-on-the-Main in 1865; and retired in 1879. Lindley introduced into sewerage and water-works construction many new features later widely adopted.

LINDNER, lĭnt′nẽr, Albert (1831–88). A German dramatist, born at Sulza and educated at Jena and Berlin. His earlier plays, *Dante Alighieri* (1855) and *William Shakespeare* (1864), were succeeded by the popular *Brutus und Collatinus* (1867), with which he won the Schiller prize. Among his later plays are *Staud und Welf* (1867); *Katharina II.* (1868); *Die Bluthochzeit oder die Bartholomäusnacht* (1871), a great success; *Marino Falieri* (1875); *Don Juan d'Austria* (1875); *Der Reformator* (1883). Consult A. von Hanstein, *Albert Lindner, Leben und Werke* (Berlin, 1888), and Hans Litterberger, *Studien zum Drama der Gegenwart* (Munich, 1896).

LINDNER, Theodor (1843–). A German historian, born at Breslau and educated there and in Berlin. In 1876 he went to Münster as professor of history, and from there in 1888 to Halle. His works include: *Geschichte des deutschen Reiches vom Ende des vierzehnten Jahrhunderts bis zur Reformation* (1875–80); *Kaiser Heinrich IV.* (1881); *Urkundenwesen Karls IV. und seiner Nachfolger* (1882); *Geschichte des deutschen Volkes* (1894); *Der Krieg gegen Frankreich und die Einigung Deutschlands* (1895); *Weltgeschichte seit der Völkerwanderung* in nine volumes (7 vols., 1901–10).

LIN′DO, Mark Prager (1819–77). A Dutch author, born in London of English parentage. He studied at Boulogne and Düsseldorf, taught in the military school at Breda from 1853 to 1865, and in the latter year went to The Hague as inspector of education in South Holland. Under the pseudonym "De oude heer Smits," he made himself famous by his sketches in the *Arnhemsche Courant*. They were published in book form (1858–65) and were collected in five volumes as *Kompleete werken van den ouden heer Smits* (1877–79). In the *Nederlandsche Spectator*, founded by him in 1856, much of his best work appeared: *Clementine* (1858), *Le Saltimbanque* (1859), and *De geschiedenis van een gentleman* (1862). He translated into Dutch Sterne's *Tristram Shandy* and many of the novels of Thackeray, Scott, Fielding, Dickens, and others. His last work was the historical *De opkomst en ontwikkeling van het Engelsche volk* (1856–73).

LINDPAINTNER, lĭnt′pīnt-nẽr, Peter Joseph von (1791–1856). A German musical conductor and composer, born at Coblenz. He studied at Augsburg, then at Munich under Winter, and somewhat later under Grätz, the contrapuntist. From 1812 to 1819 he was director of music at the Isarthor Theater of Munich, and from 1819 until his death was court kapellmeister at Stuttgart. He developed at Stuttgart one of the best of German orchestras. In 1853 he conducted the New Philharmonic concerts in London. As a composer he lacked originality and depth, but was clear, brilliant, and musician-like. Many of his songs, notably *Die Fahnenwacht*, were very popular in their time. He also wrote 28 operas, symphonies, and chamber music.

LINDSAY, lĭn′zĭ. The county seat of Victoria Co., Ontario, Canada, on the Scugog River, 65 miles northeast of Toronto (direct) on the Grand Trunk and Canadian Pacific railroads (Map: Ontario, F 5). It is connected by steam communication with the Trent Valley Canal. It contains the county buildings, a collegiate institute, and a Roman Catholic convent. It is an important railway centre, with a trade principally in lumber, grain and flour, and manufactures of doors, sashes, blinds, ironwork, beer, agricultural implements, carriages, woolen goods, boots and shoes, and extract of hemlock bark. The United States is represented by a consular agent. Pop., 1901, 7003; 1911, 6964.

LINDSAY. A Scottish family of Norman extraction. One of the race obtained lands in England from William the Conqueror; another, Sir Walter de Lindsay, settling in Scotland under David I, acquired Ercildoun and Luffness in East Lothian. The more prominent among a long list of illustrious descendants are the following; William Lindsay of Ercildoun, High Justiciary of Lothian in the latter half of the twelfth century, who acquired the lands of Crawford in Clydesdale; he married Princess Marjory, sister of King William the Lion, and had three sons, the eldest of whom inherited Crawford.—Sir Alexander Lindsay, younger brother of Sir James Lindsay of Crawford (conspicuous at the battle of Otterburn), and his son David, who became chief of the family, married the sister of Robert III, and was raised by that King in 1398 to the dignity of Earl of Crawford.—David, fifth Earl, a faithful friend of James III, and employed by him in his most important foreign embassies, who was made Duke of Montrose in 1488, a title which had never before been bestowed in Scotland but on princes of the blood royal.—Sir John Lindsay, who in 1445 was created Lord Lindsay of the Byres; the tenth Lord Lindsay of the Byres, in 1644 created Earl of Lindsay, who also became seventeenth Earl of Crawford, and held the offices of High Treasurer of Scotland and Extraordinary Lord of Session; Lord Menmuir, a Lord of Session and Secretary of State to James VI; and Alexander William Lindsay, twenty-fourth Earl of Crawford and Balcarres (q.v.). Consult Lord Lindsay, *Lives of the Lindsays; or a Memoir of the Houses of Crawford and Balcarres* (London, 1849).

LINDSAY, Alexander William Crawford, Earl of Crawford. See Crawford.

LINDSAY, or **LYND(E)SAY**, Sir David (c.1490–1555). The most popular of the early Scottish poets. He seems to have been born at Garmylton. He studied at the University of St. Andrews about 1505–08 and seems to have attached himself at once to the Scottish court as equerry (1508). In 1511 he took part in a play before James IV and Margaret Tudor at Holyrood. He became an usher to Prince James, afterward James V of Scotland, an office which he held till 1522. In this year he married Janet Douglas, described as the King's seamstress. About 1528 James V appointed him

Lyon king-at-arms (chief court herald), in which capacity he was sent on several diplomatic missions. He died before April 18, 1555. The earliest of his poems, *The Dreme* (written about 1528, though not published till 1558), is an allegory written in the seven-line stanza of Chaucer. The poet is conducted by Dame Remembrance through earth to hell and purgatory, back to the earth, and finally to heaven. The vision closes with an account of the dreadful state of Scotland—the robbery and oppression in the Highlands and on the borders. This poem was soon followed by *The Testament and Complaynt of our Soverane Lordis Papyngo* (1530), a satire on the court, prelates, and nobles, and by the *King's Flyting* (?1536), an audacious rebuke of the King's licentiousness. For the feast of Epiphany, Jan. 6, 1540, Lindsay wrote his famous morality play, *Ane Satyre of the Thrie Estaitis*, in which he denounced the clergy with especial severity. In 1554 he completed a long poem (6333 lines) called *The Monarchie*, which gives an account of the rise and fall of Assyria, Persia, Greece, and Rome, closing with a prophecy of the fall of the fifth world monarchy, the Church of Rome. Other poems are: *The Complaynt of Bagsche, the Kingis Auld Hound, to Bawtie, the Kingis Best Belovit Dog, and his Companions*, a satire on the court; *The Historie and Testament of Squyer Meldrum*, a metrical romance, having as a hero a contemporary Scottish laird; *Kittie's Confessions*, aimed at the confessional; *Ane Description of Peder Coffer*, an exposure of peddlers' tricks. For a century Lindsay's satires, abounding in humor and proverbial philosophy, were read throughout Scotland. They seem to have lost their popularity chiefly because the language in which they were written became unintelligible to all except scholars. In furthering the Reformation in Scotland they played a part hardly second to the sermons of John Knox. *The Thrie Estaitis* occupies a considerable place in the development of the drama. Consult his *Poetical Works*, edited by Laing (2 vols., Edinburgh, 1879), and *Works*, edited for Early English Text Society (5 parts, London, 1865–71).

LINDSAY, John Wesley (1820–1912). An American Methodist Episcopal clergyman and educator, born at Barre, Vt. He graduated from Wesleyan University in 1840 and from Union Theological Seminary in 1842. The next year he entered the Methodist ministry, joining the New England conference. He was professor of Latin and Hebrew in Wesleyan University from 1848 to 1860; from 1865 to 1868 was president of Genesee College (afterward developed into Syracuse University); for five years was professor of exegetical theology in Boston University School of Theology (later professor of New Testament Greek and exegesis); and from 1873 to 1883 was dean of the College of Liberal Arts of Boston University. He continued to work in the pastorate until 1895. He was a presiding elder for three terms; a delegate to the General Conference for the years 1864, 1868, and 1872; and, as charter member, remained on the board of education of the Methodist Episcopal church till his death (44 years). He was the author of the commentary on Deuteronomy in the Whedon series of commentaries.

LINDSAY, Nicholas Vachel (1879–). An American poet, born at Springfield, Ill. He studied at Hiram College, Ohio (1897–1900), at the Art Institute, Chicago (1900–03), and at the New York School of Art (1904–05). In the winters from 1905 to 1909 he lectured for the Y. M. C. A. and in 1909–10 for the Anti-Saloon League. He made several long tramping trips, during the first of which (1912) he walked from Illinois to New Mexico, and gained notice by paying his way with his verse, on the analogy of the troubadours and strolling players of the Middle Ages. He is author of *The Tramp's Excuse*, a poem (1909); *Rhymes to be Traded for Bread* (1912); *General William Booth Enters Heaven, and Other Poems* (1913); *The Congo, and Other Poems* (1914); *Adventures while Preaching the Gospel of Beauty* (1914).

LINDSAY, Robert. A Scottish chronicler, called, from his birthplace, Pitscottie (q.v.).

LINDSAY, Samuel McCune (1869–). An American sociologist, born at Pittsburgh, Pa. He graduated from the University of Pennsylvania in 1889; studied in 1889–94 at Berlin, Vienna, Rome, and Paris; and received the degree of Ph.D. from Halle in 1892. He was professor of sociology at the University of Pennsylvania from 1904 to 1907, when he became professor of social legislation at Columbia University. He served as special agent of the United States Finance Commission in 1892, as expert agent of the United States Industrial Commission in 1899–1900, and as commissioner of education for Porto Rico in 1902–04; and in 1901 he was president of the American Academy of Political and Social Science, of whose *Annals* he became associate editor. He is author of *Die Preisbewegung der Edelmetalle* (1893); *Social Aspects of Philadelphia Relief* (1895); *Railway Labor in the United States* (1902); *History of the Establishment of the Public School System in Porto Rico* (1905). He edited three of the annual reports of the National Child Labor Commission, New York (1904–07), and contributed to the New International Encyclopædia.

LINDSAY, Thomas Bond (1853–1909). An American linguist and educator, born in New York City. He graduated at Wesleyan University in 1874, and then studied in Germany. In 1878 he became assistant professor of Latin and Sanskrit at Boston University, and in 1884 was promoted to a full professorship. He wrote several articles on Latin poets for Warner's *Library of Best Literature;* edited Cornelius Nepos (1882 and 1895), Juvenal (1890), and Catullus (1902); and published *Easy Latin Lessons* (with Rollins, 1890) and *Sight Slips in Latin* (1892).

LINDSAY, Thomas Martin (1843–1914). A Scottish minister of the Free church. He was educated at the University of Edinburgh and was examiner there and assistant in logic and metaphysics. In the Free Church College at Glasgow he became professor of church history in 1872 and principal in 1902. For 15 years he was convener of the Free church foreign mission committee, and as such traveled in eastern Europe and western Asia. He translated Ueberweg's *Logic* (1871); contributed to the *Encyclopædia Britannica*, the *Cambridge Modern History*, the *Cambridge Medieval History*, and the *Cambridge History of English Literature*, but is better known for his publications on Luther and the Reformation, especially *Luther and the German Reformation* (1900) and the very valuable *History of the Reformation* (1906–07).

LINDSAY, Wallace M. (1858–). A distinguished Scottish Latinist, born in Fifeshire. Educated at Glasgow University, Balliol

College, Oxford, and the University of Leipzig, from 1880 to 1889 he was a fellow of Jesus College, Oxford. In 1898 he lectured at Harvard University; in 1899 he was appointed professor of humanity at St. Andrews University, Scotland; and in 1910 he was Sanders reader in paleography at Cambridge. His contributions to classical learning were chiefly in the fields of the historical grammar of the Latin language and of the study of Plautus. His publications include, besides many articles in the learned periodicals: a critical edition of Nonius Marcellus (1893); *Latin Language* (1894, the most important work on the subject in English; Ger. trans., 1895); *A Short Historical Latin Grammar* (1895); *Introduction to Latin Textual Emendation* (1896); *The Palatine Text of Plautus* (1896); *Handbook of Latin Inscriptions* (1898); *The Codex Turnebi of Plautus* (1898); *Plautus's Captivi* (2d ed., 1902); a critical edition of Martial (1902); *Nonius Marcellus' Dictionary of Republican Latin* (1901); a text edition of Plautus, the best available edition of that author (1904–05); a review of contributions to the study of Plautus, in *Bursian's Jahresbericht* (1906, 1912); *The Syntax of Plautus* (1907); a critical edition of Isidorus (1910); a critical edition of Festus (1913).

LINDSAY, William (1835–1909). An American lawyer, born in Rockbridge Co., Va. He was educated in Virginia and in 1854 removed to Hickman Co., Ky., where he taught school, studied law, and in 1858 was admitted to the bar. He served in the Confederate army during the Civil War; was elected to the Kentucky Senate in 1867; and, an associate justice after 1870, was Chief Justice of the State Supreme Court in 1876–78. He was again in the State Senate in 1889, was a commissioner of the World's Columbian Exposition in 1893, and in the same year was elected (a Democrat) to the United States Senate to fill a vacancy. In 1894 he was reëlected for the full term of six years, but, being a "sound-money" man, before the close of his term had become estranged from his party and voted generally with the Republicans. After his retirement from the Senate he practiced law in New York City. In 1901 he was appointed by President McKinley a commissioner for the Louisiana Purchase Exposition held at St. Louis in 1904.

LINDSBORG, lĭnz′bŏrg. A city in McPherson Co., Kans., 21 miles by rail south of Salina, on the Smoky Hill River and on the Union Pacific and the Missouri Pacific railroads (Map: Kansas, E 5). It is the seat of Bethany College (Lutheran), opened in 1881, consisting of 12 departments, including a musical conservatory which is widely known for its annual "Messiah" concerts. The city is the centre of several large Swedish Lutheran colonies and contains a fine high school and the Lutheran publication house for the West. It has considerable trade in flour, grain, broom corn, live stock, farm produce, etc., and manufactures flour, spark plugs, brooms, and brick. The water works and electric-light plant are owned by the city. Pop., 1900, 1279; 1910, 1939.

LINDSEY, lĭn′zĭ Ben(jamin) B(arr) (1869–). An American jurist and social reformer, born at Jackson, Tenn., Nov. 25, 1869. He was educated in the public schools of Jackson and at Notre Dame, Ind. At 18 he was left by his father's death the sole support of his mother and her three younger children. He obtained employment in a real-estate office in Denver, Colo., and occupied his leisure in reading law. In 1894 he entered upon the practice of law in Denver. He soon became identified with the movement for reform in legal procedure, and through his partner, Frederick W. Parks, elected to the Legislature in 1897, secured the passage of a law making the vote of three-fourths of a jury sufficient for a verdict. In 1900 he was appointed to a vacancy in the county court. His special preoccupation came to be the reform of the methods of dealing with children charged with delinquency or crime. Through his efforts an act was passed creating in the city of Denver a juvenile court which, though not the first to bear a similar name (see Juvenile Court), represented an important advance in the relation of the law to children. Lindsey was made judge of the juvenile court in 1901, and held this office continuously through successive two-year terms, although encountering strong opposition on the part of interests prejudiced by his activities, culminating in 1908 in a refusal by both the Republican and the Democratic parties to indorse his nomination for the office. Under his administration the juvenile court of Denver became famed throughout the civilized world, and many of its features have been copied, not only in a number of American States, but in foreign countries as well.

Among other measures to which Judge Lindsey contributed his influence were a reform of the registration law, greatly reducing election frauds; a reform of the ballot; State provision for the support of the dependents of persons serving in prison; extension of the probation system for prisoners; organization of public baths and playgrounds in Denver; and the institution of the fresh-air movement in the same city. He was a leader also in the fight against franchise exploitation of the city of Denver, and in the movement to abolish child labor. He carried on an active propaganda for the general adoption of the juvenile-court plan, and for political and social reform, through lectures delivered in many American and foreign cities and through the publication of books and pamphlets, of which *The Beast* (with Harvey J. O'Higgins, 1910) was widely circulated. It was first published as a magazine serial under the title *The Beast and the Jungle*. In 1906 Judge Lindsey was a candidate for Governor of Colorado, and in 1912 became a member of the Progressive National Committee. With Edwin Markham and George Creel he was coöauthor of *Children in Bondage* (1914) and he wrote the article "Juvenile Court" for the New International Encyclopædia. Consult Lincoln Steffens, *Upbuilders* (Garden City, N. Y., 1909).

LINDSEY, Charles (1820–1908). A Canadian author. He was born in Lincolnshire, England, and in 1841 went to Canada, where he was employed on the staff of the Toronto *Examiner* and of the Toronto *Leader*. He became a fellow of the Royal Society of Canada on its foundation in 1882. His publications include: *Clergy Reserves* (1851); *Prohibitory Liquor Laws* (1855); *The Prairies of the Western States* (1860); *Life and Times of William Lyon Mackenzie* (2 vols., 1862; new ed. by G. G. S. Lindsey, 1908); *An Investigation of the Unsettled Boundaries of Ontario* (1873); *Rome in Canada* (1878).

LINDS′LEY, John Berrien (1822–97). An

American physician and educator, born at Princeton, N. J. After graduating from the University of Nashville in 1839, and (M.D.) from the University of Pennsylvania in 1843, he studied theology and in 1846 was ordained to the Presbyterian ministry. He was professor of chemistry in the University of Nashville (1850–70), chancellor of the university (1853–73), and in 1850 assisted in organizing the medical department of the institution, becoming its first dean. He also organized Montgomery Bell Academy, and had a part in the establishment of the Tennessee College of Pharmacy, where he occupied the chair of materia medica from 1876 until his death. In the University of Tennessee he was professor of chemistry and State medicine from 1880 to 1897. For many years he edited the *Nashville Journal of Medicine and Surgery;* and he contributed to periodicals, published *Our Ruin: Its Causes and Cure* (1868), and was editor of *The Military Annals of Tennessee* (1886).

LIN′DUM. The ancient Latin name of the English city Lincoln (q.v.).

LIN′DUS. The ancient name of a city on the island of Rhodes.

LINE (AS. *line*, OF., Fr. *ligne*, It. *linea*, from Lat. *linea*, thread, line, from *linum*, Gk. *λίνον*, *linon*, flax). A military and naval term, applied to the regular regiments of artillery, cavalry, and infantry, in distinction from engineers and special corps or departments. While it applies universally, it has more special reference to the armies of the United States and Great Britain. Originally it referred to the troops constituting the regular line of battle. In England the terms *marching regiment* and *marching officer* were formerly much used, as synonymous with line regiment and line officer. *Line formation* is a formation in which the men, horses, or guns constituting the line are abreast of each other. It is the order in which infantry form their attack.

The engineer officers (see ENGINEERS, CORPS OF) are included among the staff officers, but by the Organization Act of 1899 they may take command of troops, provided they are on duty with engineer troops, as line officers. In the United States navy there is a similar usage and the line or combatant officers are distinguished from those with other duties, such as the medical corps, pay corps, etc. In European navies the term is used to distinguish the officers serving in the regular navy from those in the naval reserve or on coast guard or other duties.

LINE. A term used in the fine arts, by extension of its original meaning, as synonymous with drawing. The use of line in representation of visual objects in general is discussed under DRAWING and PERSPECTIVE; this article will confine itself to its use in painting. Line is of equal importance with color in a picture, the greatest colorists of the past, like Titian and Tintoretto, having also been good draftsmen. In fact, the character of a picture is often determined by the prevailing character of its lines, which is generally indicative of a particular sentiment of which it forms the expression. (See COMPOSITION.) It is impossible to discuss here the studio maxims and rules of drawing. There is, of course, such a thing as an abstract beauty of line. Curves strike us as being more beautiful than unvarying straight lines, and compound and reversed curves than simple ones. In like manner we feel that lines could continue each other smoothly, as in the human figure. But the following of cast-iron maxims would restrict the artist in practice, and destroy for the amateur the enjoyment of many of the most beautiful works of art.

As regards line in a picture there are two distinct points of view—the classical, or academic, and the picturesque, or naturalistic. The former sees in line the chief, almost the only, merit of a picture, relegating color to a position entirely subordinate. Its chief subject is the human figure, and it attempts by uniting many individual perceptions to reach the ideal. The picturesque, on the other hand, endeavors to give the soft outlines of nature, and is concerned rather with the general effect than with details. Its chief purpose is to give the character of objects, the appearance of life, and to do this it emphasizes salient points to the neglect of details. The character of drawing used in the portrayal of an object—whether classical or picturesque—is determined by the nature of the object, the purpose of the artist, and, above all, by his individuality.

Among ancient peoples the Greeks were very accurate draftsmen, this being one respect in which their painting at least equaled that of modern times. Among the Italians the Florentines, from Giotto to Michelangelo, were preëminent in line, though it was also the forte of the Paduan school (Mantegna). The Flemings of the fifteenth century (Van Eyck, Memling) and the Germans of the sixteenth (Dürer, Holbein) also excelled in line. The Venetians were colorists rather than draftsmen, as were also the Spaniards (Velazquez) and the Netherlanders (Rubens, Rembrandt). Classical drawing was carried to the most logical extreme by David and his followers in France, the picturesque view being represented by Delacroix and the Romanticists, whose successors in this respect, the Impressionists, practically deny the existence of line. Most artists of the present day, however, combine both points of view in their practice. Consult the authorities referred to under COLOR.

LINE, MATHEMATICAL. A magnitude of only one dimension, defined as the path of a moving point or the boundary between adjacent portions of a surface. Lines are classified as *straight*, *broken*, *curved*, or *mixed*. The broken line is composed of straight lines. A mixed line is composed of straight and curved lines. The word taken alone is generally understood to refer to a straight line.

LÍNEA, lē′nȧ-ȧ, LA. A town of Spain. See LA LÍNEA.

LIN′EAL (Lat. *linealis*, relating to a line, from *linea*, line). In law, the relationship of persons who constitute successive generations in a direct line of descent from a common ancestor. It is the direct opposite of "collateral" as applied to consanguinity or relationship, which means persons who have a common ancestor but do not bear the relation of ancestor and descendant as to each other, as cousins, who have a common ancestor on either the paternal or maternal side but have not the same immediate ancestors, that is, their parents. See COLLATERAL; CONSANGUINITY; DESCENT; RELATIONS.

LIN′EAR ACCELERATION. See MECHANICS.

LINE ENGRAVING. That in which the line is cut into copper or steel plates by means of a pointed instrument called the burin (q.v.). The design is printed in black lines from the incisions in the metal, as distinguished from wood engraving, in which the design is printed from the parts in relief. Line engraving on copper, which was the metal generally used, is also called copper or copperplate engraving. The burin is a slender steel bar, square, or less usually triangular in section, with this peculiarity, that its working end is cut off in the direction of the diagonal plane so that the most projecting point—that farthest from the handle—is a not very acute solid triangle bounded by three planes which meet in very sharp edges. This steel bar is set in a short wooden handle having a rounded form so shaped that the hand may push it strongly, point on. When this tool is forced along the surface of a metal plate with the axis of the steel bar slightly inclined to the surface of the plate, it cuts a groove, forcing out the metal in a curled shaving; and according as it is forced in more or less deep it makes the incision more or less wide. The artist having before him, let us say, a patch of shade in the drawing which he is to copy, that patch having a definite size and the depth of the shade varying in an artistic gradation from light to dark, it is his business to reproduce that shade on the paper which is to be printed from his engraved plate by means of applied ink; and therefore, as he has at his disposal only solid black lines by which to represent shade, he has to decide on the number, the direction, the fineness, and the closeness of the setting of those lines.

Some burinists have worked with very fine lines, put in as simply as those of the etcher—short lines, nearly parallel, drawn with all the apparent ease of a pen-and-ink draftsman. Others, especially the line engravers of the seventeenth and eighteenth centuries, have used lines of varying breadth, very wide in some part of their length and tapering to a point, or nearly so; and these lines have been used in one system, nearly parallel to one another, and have also been used crossing each other like the crosshatching recommended by some teachers of drawing in black and white. A still further development of the process has involved the putting of a dot or cut in the metal in each lozenge-shaped space left by such crosshatching; but this has not been approved by the critics of later times and may be thought to be abandoned. Line engraving has not been in very common use since the middle of the nineteenth century, and this, in part, because of the strong feeling caused by the use of etching and dry-point work by artists to render their own thoughts, with the result that line engraving, a process much too slow and mechanical to please the artist who is accustomed to painting or drawing in monochrome, is neglected except for the reproduction of paintings and the like. The very common use of line engraving to do just such work as that, viz., the close copying of pictures and statues in the public galleries of Europe, has aided in this general condemnation of burin work as dull and uninteresting. The production, since 1850, of a few works of the burin in which great artistic intelligence and much originality are shown has not sufficed to restore the popularity of the art. Moreover, the immense advance in photographic engraving of all sorts has helped in the comparative abandonment of this with the other uses of the engraver's art.

History. As stated in the article ENGRAVING, the custom of printing trial impressions of niello plates may have originated the art of engraving for printing upon paper. This origin must have taken place in the course of the fifteenth century, and the result of the newly invented process is found in such early work as that ascribed to Baccio Baldini. Such prints are, of course, rare, but they do not need rarity to make them singularly valuable, both historically and in the way of artistic merit. Contemporary with them are a great many small prints, known to collectors as *niello* or niello prints, these being evidently made by rubbing with ink the coppers prepared for niello work and taking impressions on paper to show the design. From 1450 until the close of the century these works and those of Robetta of Florence, those of Lombardy, and those of Schongauer and others in Germany, represent a great part of the artistic movement of the time. In Germany the rôle played by engraving was especially important, since it dominated rather than was influenced by painting. The earliest engravings, whether of Italian or German origin, show a very imperfect knowledge of the power of the burin and the resources of the burinist's art. The outline is drawn on the metal with singular grace and charm, this extending even to the most refined qualities of facial expression; but this outline is not supported by a complete system of light and shade. The burin is used for thin and light lines only, without imitation of pen or pencil drawing. The early Italians conceived the shading as distinct from the outline, rendering it by means of straight lines. But the Germans shaded more skillfully, letting the shadow follow the forms of the objects and making use of curved lines for the shadow, a method adopted later by the Italians. The work of Jacopo dei Barbari (the master of the caduceus), an artist of whom little is known, is among the most poetical of the time, and Sandro Botticelli, in his designs for the illustration of Dante—designs thought to have been engraved by Baccio Baldini—is supposed also to have engraved a few plates himself. In fact, the painters of the time experimented with the burin very nearly as the painters of the second half of the nineteenth century worked with the etching needle. The best of the engravers in the early Italian manner, both in power of line and skill in shading, was the painter Andrea Mantegna. By far the most important figure in early German engraving was Martin Schongauer (died 1488), who used the burin with great power and freedom and excelled all before him in shading. It is important to note that the early engravers had no thought of the comparative lowering of their art to a process of mere copying.

The sixteenth century is a time of amazing fertility and artistic results in line engraving. Especially during the years previous to his death in 1528, Albrecht Dürer (q.v.) achieved greater delicacy and skill in shading and an unequaled facility and power in the use of the burin, producing designs of extraordinary originality and refined sentiment. His most famous pieces are the "Melancholia" and the so-called "The Knight, Death and the Devil" and "St. Jerome in his Study"; but his "Adam and Eve," the noble designs called the "Coat of Arms with the Skull" and the "Coat of Arms with the Cock," and several of the portraits, are of equal artistic importance. (For details, see DÜRER, ALBRECHT.) In the Low Countries Lucas van Leyden worked until 1533, and his prints, though not possessing the magnificent strength of those of Dürer, are yet charming for their quaintness; and his portrait work has singular attractiveness because of its apparent fidelity to individual expression and to details of costume. Barthel Beham produced less work than his predecessor and probable teacher, Dürer, his life being short, but he is known as the maker of the finest burin engraving existing if technical qualities are considered, and one equal to any similar artistic work of the kind, viz., portraiture, in loftier expressional qualities. This astonishing print is the portrait of the Emperor Charles V in his youth, the plate being dated 1531. Marcantonio Raimondi (q.v.) has been the most reputed and admired of burin engravers, but this largely because of the traditional dependence of his art upon the teachings of Raphael, and the fact that he reproduced many of Raphael's drawings, now lost—these reproductions being not necessarily close, though having much of the original significance. In a curious way Marcantonio links together the earliest and the later schools of line engraving; for he has a refinement of outline in no way supported by his system of light and shade, in which he resembles the earliest men, while his deliberate preference of a life of copying to the career of an original designer in black and white makes him in a way the founder of that unfortunate later school which looked upon line engraving as a technicality, to be used only for the rendering, usually inadequate, of important pictures. Agostino Carracci (q.v.) worked during the second half of the sixteenth century, producing original designs as well as copies, and in France the able workmen Abraham Bosse and Israel Silvestre carried the traditions of originality and native force far into the seventeenth century. Poetical inspiration was denied them, but they have left an admirable record of their time in designs of complete individuality. The most important factor in line engraving of the seventeenth century was the group of engravers employed by Rubens to reproduce his paintings, of whom the most important were Vorstermann, Paul Pontius, and the brothers Van Bolswert. They substituted modeling for the meagre Italian outlines, broad masses for the detailed treatment of German work, and adopted a new system of light and shadow.

During the reign of Louis XIV France was at the head of Europe in the art of engraving and was represented by Robert Nanteuil (q.v.), Gérard Edelinck, a Fleming, who had migrated to Paris, and Antoine Masson, who worked after paintings by the great artists of the day, but without a minute adherence to the original. Nanteuil was indeed the inventor of those devices, those combinations of lines and dots and that excess of crosshatching, which were so abused by his successors; but his own work is of almost uniform good taste and dignity—formal, indeed, in the spirit of the time, but retaining a force and fire characteristic rather of the original work than of the copyist. Jean Pesne engraved the paintings of Poussin with a similar boldness, transferring the artist's composition from the canvas to the smaller study in black and white. Gérard Audran (died, 1703) was able to give power to huge prints, rather closely studied from the paintings of his contemporaries, Mignard and Poussin, as well as to reproductions of Raphael's wall pieces.

In the eighteenth century line engraving is delicate and refined and the portraits of the time are of singular interest. but it is devoted to a more feeble system of design and largely used for book illustration. The celebrated *Livres à vignettes*, illustrated by Charles Eisen, Charles Nicolas Cochin, Pierre Philippe Choffard, and Nicolas de Launay, as the most celebrated of a large school of engravers, form a separate branch of art study, the number of the works being very great and their merit singularly uniform. In still later times, Volpato (died, 1803) and Raphael Morghen (died, 1833) carried over the assumed grand style of the earlier workmen into the nineteenth century; and with their works closes the history of line engraving of the traditional school. The nineteenth century saw the final collapse of line engraving in favor of cheaper and more rapid processes. Along certain lines progress was indeed made—in local color, light and shade, and textures. In France a few powerful and self-centred artists like François Forster (died, 1892) and Henriquel-Dupont (died, 1892) followed a resolute course, working in the spirit of such a period or such a master of the past as their personal characteristics made easy, and producing valued prints. Since 1850 line engraving has been kept alive mainly by the government institution, La Chalcographie du Louvre. There have been but few exceptional artists, like Ferdinand Gaillard, to glorify the second half of the nineteenth century. In Great Britain the art was greatly fostered by the commercial enterprises of John Boydell (q.v.), who endeavored to establish a national art. Mixed processes, in which line engraving was used for finishing, may be especially seen in the wonderful work after Turner. In Germany good line engraving, even in its older form, retained great popularity. Good work has been produced as well in the old manner as in the subtle mixed processes like those of Stauffer-Bern. In the United States, line engraving, although practiced in a primitive fashion in New England and other colonies, and not a little used in the nineteenth century for illustration, never attained the importance of an independent art.

LINEN (Fr. *lin*, Ger. *Leinen*, Lat. *linum*). Yarn, thread, or cloth made from flax (q.v.). Also, a general term for tablecloths and napkins (table linen), sheets and pillow cases (bed linen), shirts, handkerchiefs, and collars (body linen), whether of all linen, part linen and part cotton, or all cotton. Linen thread is used almost exclusively in the manufacture of handmade laces. (See Lace.) Table linen is made almost exclusively in damask weave. (See Damask.) While we owe the early development of silk to China and of cotton to India, the mother country of linen is Egypt. Flax is indigenous to the valley of the Nile, and Egyptian graves from 2000 to 4000 years old have preserved for us linen tapestries, embroideries, and plain cloths, many of them of a texture almost incredibly fine. The Bible often mentions flax in Egypt and tells us that Pharaoh arrayed Joseph in vestures of fine linen (about 1700 B.C.). For centuries the Phœnicians transported linen cloths from Egypt to all parts of the Mediterranean world. Linen has from time immemorial been symbolic of purity, and purple and fine linen of royalty. This is because linen can be bleached to snowy whiteness, and on account of its resistance to coloring matter does not stain easily, the long fibres having few short ends to become fuzzy like cotton. The fact that linen absorbs water rapidly makes it the best material for towels; its hard, smooth, lustrous surface renders it unsurpassed for table use; and it is cool for summer wear, because a splendid conductor of heat. But the difficulty of dyeing it usually gives the preference to cotton, silk, or wool when color is desirable. The stiffness that causes it to lie flat and smooth on a table or around the wrist or neck makes it undesirable for clothing generally, because it retains wrinkles obstinately.

As everybody knows, the United States is primarily a cotton country. (See Cotton.) On this side of the Atlantic linen is to be classed with silk as an article of luxury. In the words of the United States census for 1904: "The linen manufacture is exotic in this country. Relatively little attention is given to the preparation of the flax fibre for manufacture, and that which is prepared is adapted only to the cheapest processes. Imported material is employed almost exclusively in the spinning of yarns and the weaving of fabrics. There has never been a successful attempt to produce fine goods at a profit." The total production of linen goods, consisting mostly of thread, twine, and toweling, was only $6,385,218 in 1909, as compared with $4,368,159 in 1899 and $2,880,341 in 1889.

In Ireland the situation is quite different. Moore says, in the introduction to his book on *Linen:* "Cotton may have its probable limitation with regard to its users, but linen is universal and cosmopolitan, being found in some form or other alike in the cottage of the labourer and in the palace of the sovereign." While this is an exaggeration, it sounds natural from the mouth of a Belfast man, because Belfast is the centre of the Irish linen trade and is famous throughout the world as Linenopolis. The value of the linen exports from the United Kingdom in 1913 was £8,247,571 (about $40,000,000), of which Ireland contributed four-fifths and Scotland most of the rest. Of these exports the United States takes about one-half, handkerchiefs alone amounting in 1913 to $2,067,000. That the manufacture of fine linens is likely to be transplanted to the United States as a result of the war in Europe is improbable. The amount of hand labor necessary in the preparation of the flax for spinning, and in the spinning and weaving, is prohibitive. But it is probable that the important linen and lace industries of Belgium will seek at least a temporary refuge elsewhere—in France, Holland, Scotland, or Ireland.

Spinning, Bleaching, and Weaving. After the flax plant has passed through the processes of retting, grassing, and scutching, it is ready for the spinning mill. Here there are repeated combings and cleanings to remove impurities, followed by hackling to separate the fibres, and drawing to produce roving ready to be spun. The best flax spinning is done in a moist atmosphere; indeed, the finest yarns can be spun only when wet. The hand spinner of olden time kept a bowl of water beside her, in which she moistened her fingers as she spun. Linen is more difficult to weave than cotton because less elastic, and liable to break under sudden strain. For a long time after the introduction of power looms fine damasks continued to be woven by hand. Now hand weaving is confined in Ireland to small quantities of the very finest napkins, doilies, and small tablecloths; but coarse crashes and many of the cruder varieties of European linens are woven on hand looms by the peasants of remote villages. Linen bleaching is a most elaborate procedure. Mrs. Earle, in her *Home Life in Colonial Days* (New York, 1900), says that the American colonists put linen through some 40 processes of wetting, washing, acid bleaching, rinsing, soaking, grass bleaching, etc., before attaining pure white. These processes required many weeks. Linen loses from 25 to 30 per cent of its weight in bleaching and is much more weakened by modern chemical than by the ancient grass methods. The modern half bleach is obtained by boiling the linen in sodium carbonate or in soda ash; then treating with bleaching powder, then with dilute sulphuric acid. After each operation it is thoroughly washed. For a three-fourths bleach the cloth is then spread on the grass, and sun and air do their work. For a full bleach (pure white) all of these processes are several times repeated. See Bleaching.

One easy way to tell linen from cotton is to set one of the threads on fire. If it is cotton, it will blaze up and continue to burn. If it is linen, it will smolder. Another and even simpler way, and one commonly practiced by purchasers in shops, is to wet the finger in the mouth and place it under the cloth. If the moisture comes quickly through, the cloth is linen.

LINEN CHEST. See Furniture.

LINEN WEDDING. See Wedding Anniversaries.

LINE OF DEMARCATION. See Demarcation, Line of.

LINE OF SIGHT. The straight line passing through the sights of the piece; at the instant of firing this line passes through the target. The direction of the axis of the bore when the projectile leaves the muzzle is called the *line of departure.* See Ballistics.

LINES OF FORCE, Electric. See Electricity.

LINES OF FORCE, Magnetic. See Magnetism.

LING (MDutch *linghe*, *lenghe*, Dutch *leng*, Ger. *Länge*, *Leng*, ling, from AS. *lang*, Goth. *laggs*, OHG., Ger. *lang;* connected with Lat. *longus*, OChurch Slav. *dlŭgŭ*, Lith. *ìlgas*, OPers. *drānga*, Skt. *dīrgha*, long). An important species of cod, *Molva molva*, abundant throughout the northern European seas and in value almost rivaling the cod. In form it is much more elongated than the cod, has two dorsal fins and one anal fin, and has a barbel at the extremity of the lower jaw. The ling is generally 3 or 4 feet long, sometimes more, and has been known to weigh 70 pounds. The color is gray, inclining to olive; the belly, silvery; the fins edged with white. The ling is a very voracious fish, feeding chiefly on smaller fishes. It is also very prolific and deposits its spawn in June, in soft oozy ground near the mouths of rivers. It is found chiefly where the bottom of the sea is rocky. Great numbers are caught in the same manner as cod, by hand lines and long lines, and are sent to the markets in the form of stockfish.

In the United States the fresh-water cod (*Lota maculosa*) is known about Lake Ontario by this name. See Burbot; Cultus Cod.

LING. A plant of the genus *Erica;* also applied to heather, *calluna vulgaris.* See Heath.

LING, Pehr Henrik (1776–1839). A Swedish dramatist and poet, and originator of the Swedish form of military, medical, and school gymnastics. He was the son of a country clergyman settled at Ljunga in Småland. After studying at Vexiö he spent a year at the University of Lund; seems to have been a clerk and tutor in modern languages in and near Stockholm for five years; from 1799 to 1804 he prosecuted linguistic and literary studies in the university and royal library at Copenhagen, acquiring a lifelong interest in the old Norse mythology and sagas. Here he also mastered the art of fencing, under two French teachers, and through visits to Nachtegall's private gymnasium was introduced to the Guts-Muths gymnastics. In 1804–12 he was fencing master at the University of Lund and during this period elaborated his original system of bayonet fencing and gymnastics and also published the first of his dramatic works. In 1813 he proposed to the state authorities the founding of a national training school at Stockholm from which all Sweden should be supplied with teachers of gymnastics. The King approved the plan, made Ling director at a fixed salary, and in 1814 the Royal Central Institute of Gymnastics was accordingly opened. In this he labored for the rest of his life and meanwhile published the long series of dramatic and other poetical works which won for him membership in the Swedish Academy, the title of professor, and decoration with the Order of the North Star. Ling attempted to give to gymnastics a scientific basis, and under his successors at the Central Institute the art has been developed along the three lines which he had in mind at the start, i.e., as an agent in training men for the army and navy, as a therapeutic measure, and as an integral factor in school life. His *Asarne* (1816, 1834) includes the entire mythology and ancient legendary history of the Scandinavian race, and in his numerous dramas he sought to portray momentous epochs in Swedish history.—Hjalmar Fredrik Ling (1820–86), his son, educated under private teachers, at the Central Institute, and in Paris, was installed as teacher in the Central Institute in 1843, and from 1858 to 1882 was head teacher in the section of school gymnastics. This side of his father's system he developed with great ability. He made nearly 2000 pen drawings of gymnastic positions and movements, about 500 of which appear in a book published in 1893.

LINGA, lĭṉ′gȧ (Skt., symbol). In the sectarian worship of the Hindus, the phallic emblem of the generative power of nature. The Linga worship prevails with the Saivas, or adorers of Siva. The manner in which the Linga is represented is generally inoffensive—the pistil of a flower, a pillar of stone, or other erect and cylindrical objects, being held as appropriate symbols of the generative power of Siva. Its counterpart is the *Yōni*, or the symbol of female nature as fructified and productive. The Linga is the sectarian badge of the Lingayats or Lingaits of South India. Consult Sir R. G. Bhandarkar, *Vaisnavism, Saivism, and Minor Religious Systems* (Strassburg, 1913). See Hinduism; Phallicism.

LINGAH, lĭn-gä′. A seaport of Persia, the second in importance, situated in the Province of Laristan, on the Persian Gulf, just west of the Strait of Ormuz and about 300 miles southeast by sea from Abushire (Map: Persia, F 9). It has an important bazar. There is an extensive transit trade, the main item being pearls, which pass through Lingah on the way from the Arabian fisheries to India. Other articles in its trade are rice, gold, and cotton stuffs. Lingah has regular steam communication with British India and has a British post office. Pop. (est.), 15,000, including a large number of Arabs. Arabs held the port until 1898, when Persian troops took possession.

LINGARD, lĭṉ′gärd, John (1771–1851). An English historian. He was born of humble parentage at Winchester, Feb. 5, 1771, and, being destined for the priesthood, was sent to the English college of Douay in France, where he remained until that college, in common with most of the religious establishments of France, was broken up by the disorders of the Revolution. On his return to England in 1793 he became tutor in the family of Lord Stourton. The act called the Catholic Relief Act having enabled Catholics to open schools in England, the Douay community was transferred to Crook Hall and ultimately to Ushaw, near Durham. In 1794 Lingard rejoined his companions at Crook Hall, where, after entering the priesthood, he continued as professor of philosophy, prefect of studies, and vice president until 1811, when he accepted the humble cure of Hornby, near Lancaster, which he continued to fill until his death (July 17, 1851). Lingard's first important work was the *Antiquity of the Anglo-Saxon Church* (1806; reprinted in 1810, and afterward in a much enlarged ed. of 2 vols., 1845). This was but the pioneer of what eventually became the labor of his life, his *History of England until 1688*, in eight quarto volumes (London, 1819–

30). Before his death it had passed through six editions, frequently revised, the last of which, in 10 volumes, appeared in 1854–55. From its first appearance it attracted much attention, being founded on a careful study of the original sources. Although written in a conciliatory spirit, it was criticized with considerable asperity in its polemical bearings; but the author in his replies displayed so much erudition and such careful consideration of the original authorities that the result was to add materially to his reputation as a scholar. He was the recipient of many honors in recognition of his services, among others of a pension of £300 from the crown. Consult Gardiner and Mullinger, *Introduction to the Study of English History* (London, 1881), and Haile and Bonney, *Life and Letters of John Lingard* (ib., 1911).

LINGAYÉN, lēn′gȧ-yān′. The capital of the Province of Pangasinán, Luzon, Philippines (Map: Philippine Islands, C 2). It is situated at the head of the Gulf of Lingayén, on a low and fertile alluvial island in the delta of the Río Agno, 8 miles west of Dagupan. It has many substantial stone houses, a handsome church, a post office and telegraph station. It is an important trade centre, and, through the station at Dagupan, is connected by rail with Manila. It was founded at the end of the sixteenth century by the Augustine fathers, who in 1611 retired in favor of the Dominicans. Pop., 1903, 21,529.

LINGAYÉN, Gulf of. A large bay or gulf of the China Sea indenting the west coast of north Luzon, Philippines (Map: Philippine Islands, C 2). It is 20 miles wide at the entrance between Santiago Island on the west and Point San Fernando on the east; it extends inland about 30 miles. It is exposed to squalls and typhoons, the latter especially in September and October. The east shore is bordered by high mountains; the south is low and consists of the large delta of the Agno River. The largest islands are Santiago and Cabarruyán. The principal ports on the gulf are St. Thomas on the east, Lingayén and Port Sual on the south, and Port Bolinao on the west.

LINGELBACH, lĭng′el-bäG, Jan (1622–74). A Dutch genre and landscape painter, born at Frankfort-on-the-Main. He went to Amsterdam in 1637, was in Paris in 1642, and, having pursued his studies in Rome from 1644 till 1650, settled at Amsterdam. There his style was greatly influenced by Wynants, in whose landscapes he often supplied figures and animals, and by Wouverman, whose pupil he probably was, and whom he successfully imitated. He also inserted figures in the landscapes of Hobbema, Koninck, and others. He painted Italian seaports, landscapes, hunts, fairs, and other genre scenes, in a cool and often delicate silvery tone, and ranks high for skill in composition, good drawing, and careful execution. His pictures are to be found in almost every gallery of Europe. One of his principal works is the "View of the Dam and New Town Hall" (1656), in the City Hall at Amsterdam, noteworthy for the individual character of the numerous figures and the fine effect of the fresh morning light. In Amsterdam Museum are a rich "Italian Harbor" (1664) and a "Riding School," in which he rivals Wouverman. The "Seaport in Asia Minor" (1670) in The Hague Museum and a "Vegetable Market" (1670) and "Seaport" in the Louvre are remarkable for a warmth of coloring quite unusual in this painter. The Metropolitan Museum, New York, possesses a "Battle Scene" and "Dance of Peasants."

LINGENTHAL, lĭng′en-täl, Zachariä von. See Zachariä von Lingenthal.

LINGG, lĭng, Hermann von (1820–1905). A German dramatist and poet, born at Lindau. He was educated as a military surgeon. His *Poems* (1853) are of great elegiac originality and remarkable for their imagery. He was the best epic poet of the Munich school. His greatest power appeared in his epic *Völkerwanderung* (3 books, 1866–68). He wrote also *Vaterländische Balladen* (1869) and other volumes of verse, the dramatic poem *Die Walkyren* (1864; 2d ed., 1865), the tragedy *Catilina* (1864), and other dramas. His latest poems are: *Jahresringe, Neue Gedichte* (1899); *Meine Lebensreise* (1899); *Schlussrhythmen und Neueste Gedichte* (1902). Selected poems, edited by Paul Heyse, appeared in 1905 (Stuttgart). Consult: Rupert Kreller, *Die Völkerwanderung von Hermann Lingg und das Gesetz der epischen Einheit* (Munich, 1900); Arnulf Sonntag, *H. Lingg als Lyriker* (ib., 1908); Frieda Pont, *H. Linggs Biographie* (ib., 1912).

LINGONES, lĭn′gȯ-nēz. See Langres.

LINGUA FRANCA, lĭṉ′gwȧ frăṉ′kȧ. The common language spoken in the Mediterranean countries by sailors, traders, and soldiers, in dealing with natives of different nationalities, especially with Arabs, Turks, and Africans; similar thus to the pidgin English and pidgin Japanese of the Orient, the Creole dialects of Guiana, the Malay of Polynesia, the African Suhali, the Chinook of the Columbia River valley, etc., all of which, under the influence of the other meaning of *franca*, free, are sometimes called *lingue franche*. The term originated in the name *franc*, 'French,' used by the Arabs to designate the Crusaders and hence any Latin Christian (the Byzantine Christians were called *rums*). The predominance of Venice and Genoa in the Levant came to make the Italian the *franc* par excellence, and in fact the lingua franca of the Levantine Mediterranean has a predominant Italian base, with an admixture of Arabic, Greek, and African elements, and more rarely of French, Spanish, and Portuguese. In Tunis and Algeria, French, especially in recent years, has been important in contributing a large vocabulary to the lingua franca, as has Spanish in Morocco and southern Spain; but even in these regions Italian shows great tenacity. The characteristics most prominent in the lingua franca are, as regards syntax, the reduction of all verb forms to the infinitive for present and future tenses and imperatives and to the past participle for past tenses; of all pronouns to the objective case, of all nouns to one number (either singular or plural): *ti stare bona genti*, 'you are a good fellow.' The objective case is often represented, as in Portuguese, by the preposition *per*, 'for': *mi amar per ti*, 'I like you.' As regards vocabulary, the substitution of picturesque words for the less expressive (*cunciare*, 'to fix,' has become almost universal for *fazir*, 'to do'; so *massar il fogo*, 'to kill, put out, the fire') and the alteration of Romance words by giving them the meaning of words of similar sound in some other language: e.g., *fantasia*, 'fancy, imagination,' has come, under Arabic pressure, to mean 'conceit, boastfulness'; *no pigliar fantasia*, 'don't get impudent,' and the Italian *giandussa*, 'boil,' to mean 'plague': *Saint Jean venir, gandouf andar*, 'St. John comes, the plague goes.'

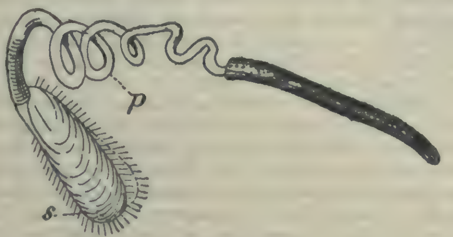
The earliest mention of the lingua franca occurs in Venetian trading documents of the eleventh century. Of the thirteenth century is an Italian poem in dialogue between an Italian and a native girl of the Gerba Islands, the latter using the lingua franca, which is playfully satirized by the poet. In the sixteenth century Levantine characters were frequently introduced in the Italian comedy, as in the *Cingana* of Giancarli di Rovigo (1560), and they were made to speak this humorous dialect. Such types occur in the Spanish plays of Lope de Vega, Acevedo, Guevara, and Calderón. From the improvised *Commedia dell' arte*, as well as from his acquaintance with Levantines in Venice, Carlo Goldoni conceived his delightful *Impresario delle Smirne;* though perhaps the most famous examples of the lingua franca on the stage are furnished by Molière's *Bourgeois gentilhomme*. Extensive specimens of the Spanish variety of lingua franca occur in Haedo, *Topografia é historia general de Argel* (Valladolid, 1612); of the French in the *Dictionnaire de la langue franque* (Marseilles, 1830), published by the French government for soldiers. Consult Hugo Schuchardt, "Die lingua franca," in *Zeitschrift für romanische Philologie* (Halle, 1909).

LIN′GUAGLOS′SA. A town of Sicily, in the Province of Catania, on the northeast slope of Mount Etna, 1725 feet above the sea and 37 miles from Messina. Remains of the lava flow from the eruption of 1566 are to be seen here. It has several interesting churches and a small theatre. It is on the edge of a rich and densely peopled agricultural region. Pop. (commune), 1901, 13,121; 1911, 12,653.

LINGUET, lăɴ′gȧ′, Simon Nicolas Henri (1736–94). A French publicist, born at Rheims. After traveling through Poland and Spain, he went to England, where he began to publish in London his *Annales politiques*, which under various changes of name he edited from 1777 to 1792 in Switzerland, Brussels, and again in London. For a time it received the support of the Austrian government, as Linguet advocated many of the Emperor Joseph's reforms. He returned to France in 1780 and was confined in the Bastille for two years for his virulent attack on the Duc de Duras. While in prison he wrote his *Mémoires sur la Bastille* (1783). After this he went to Brussels and remained there until the Revolution was almost over. But he returned too soon (1791) and, on the trumped-up charge of having "flattered the despots of London and Vienna," was guillotined in 1794. Consult Jean Cruppi, *Un avocat journaliste au XVIII siècle* (Paris, 1895).

LINGUIS′TICS. See Philology.

LIN′GULA (Lat., little tongue). A group of brachiopods, characterized by the possession of a shell, the valves of which are not hinged, but are connected by muscles, which open and close them by a more or less lateral movement; an oval opening is present near the anterior end of the animal; there is a long, fleshy stalk, which passes out from the rear between the valves of the shell. These brachiopods live in the seas of warm climates, particularly of the Indian Archipelago and Polynesia. An American species (*Glottidea pyramidata*) is common in Chesapeake Bay and off the coast of North Carolina. It has a shell about 1 inch long and ½ inch wide; the stalk is 2 or 3 inches long. The valves of the shell are brown, very flat, thin, and horny. The outer end is broad, while the other end is much narrowed; the stalk comes from between the narrow ends. The living species of lingula occur only in rather deep water on muddy or sandy bottoms. Only seven or eight species are known to be living now. The genus *Lingula* has long been considered as the oldest-known living organism, its shells having been found in all geological formations from those of late Cambrian to those of Pliocene time. The genus *Lingulella* flourished in the early Cambrian period. The species that occur in rocks of Ordovician age differ only slightly from the modern ones.



LINGULA.

A modern lingula: *s*, shell; *p*, peduncle or stalk, terminating in a tube of agglutinated sand grains.

LINIERS Y BRÉMONT, lē-nyĕrs′ ē brā′-mônt, Santiago Antonio María de (1756–1810). A Spanish naval officer and administrator, born of French parentage at Niort, Deux-Sèvres. His name was originally Jacques Antoine Marie Deliniers-Brémont. His father was a Loyalist sailor, and after the Revolution he entered the Spanish navy and had already had a varied and brilliant career before he was sent to the Río de la Plata in 1788. He fought against the English under Admiral Beresford at Montevideo in 1806 and at the head of a small fleet forced Buenos Aires to surrender in 1807. The English now marched upon Buenos Aires, and a desperate fight occurred before the city. After making great havoc in the enemy's lines, Liniers retired into the city and defended it so successfully that the English finally evacuated the valley of the Río de la Plata. For this service he was made chief of squadron, Viceroy, Governor, and Captain General of the provinces of the Río de la Plata. In 1808 he proclaimed Ferdinand VII and refused to obey the orders to proclaim Joseph Bonaparte. Thereupon, because of his foreign birth, he was requested to leave the country. Desirous of peace and recognizing that his foreign birth placed him under suspicion (despite his refusal to proclaim Joseph Bonaparte), he asked the Spanish government to replace him as Viceroy; and upon the arrival of Baltasar Hidalgo de Cisneros in 1809, issued a proclamation pointing out the qualifications of the new Viceroy and asking loyal support for him. The revolution that promptly followed these events forced Liniers to take up arms again for the Royalists. He raised a small army and marched on Buenos Aires, but he was captured by the revolutionists and executed with several of his followers.

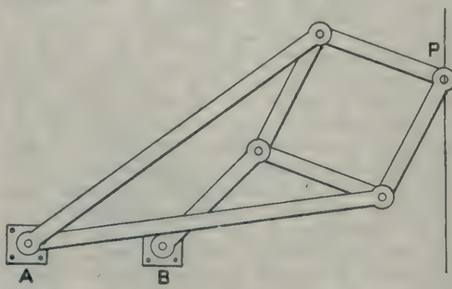
LINIEVITCH, lēn-yĕ′vich, Nikolai Petrovitch (c.1838–1908). A Russian general, born in the Government of Chernigov, where, too, he was educated. He entered military service at 17, served in the Caucasus at the age of 21, fought in the Russo-Turkish War and in the Turkestan campaigns, was made major general in 1891, and in August of 1900 assumed command of the Russian detachment with the allied forces at Pekin. For a time in 1904 he was Governor General of the Amur Province, later commanded at Vladivostok, and in November of 1904 became commander of the First Army under General Kuropatkin. After the battle of Mukden (March, 1905) he succeeded Kuropatkin as commander in chief of the Russian land forces in the East. See RUSSO-JAPANESE WAR.

LIN′IMENT (Lat. *linimentum*, from *linire*, to smear). A fluid preparation for external application, generally having soap or some fatty substance as a basis. A liniment is physically an ointment having the consistence of oil; chemically a soap, i.e., a compound of oil and an alkali. In consequence of their slighter consistence liniments are rubbed into the skin more readily than ointments. Among the most important of them are *liniment of ammonia*, which is prepared by mixing and shaking together spirits of ammonia and olive oil and is employed as an external stimulant and rubefacient to relieve neuralgia and rheumatic pains, sore throat, etc.; *soap liniment*, or *opodeldoc*, the constituents of which are soap, camphor, and spirits of rosemary, and which is used in sprains, bruises, rheumatism, etc.; *liniment of lime*, or *carron oil*, which is prepared by mixing and shaking together equal measures of olive or linseed oil and limewater (it is a soothing though very dirty application to burns and scalds, and from its general employment for this purpose at the Carron Iron Works, England, has derived its popular name); *camphor liniment*, consisting of camphor dissolved in olive oil, which is used in sprains, bruises, and glandular enlargements. Other liniments mentioned in the United States Pharmacopœia are the liniments of belladonna, cantharides, chloroform, subacetate of lead, mustard, and turpentine, or *Kentish ointment*.

LI′NIN (from Lat. *linum*, flax). The threadlike network which forms the framework of the nucleus (q.v.). This network does not take stains, and along it there are distributed stainable chromatin granules.

LINK, HEINRICH FRIEDRICH (1767–1850). A German botanist, born in Hildesheim. He studied medicine and natural science in Göttingen and in 1792 became professor of chemistry, zoölogy, and botany at the University of Rostock. He visited Portugal in 1797 in company with Hoffmansegg, and in 1811 he became professor of chemistry and botany at Breslau. In 1815 he became professor of natural history and the director of the Botanical Gardens in Berlin. His works include: *Elementa Philosophiæ Botanicæ* (1824; 2d ed., 1837); *Das Altertum und der Uebergang zur neuern Zeit* (1842); *Anatomisch-botanische Abbildungen zur Erläuterung der Grundlehren der Kräuterkunde* (1837–42); *Ausgewählte anatomisch-botanische Abbildungen* (1839–42); *Anatomie der Pflanzen in Abbildungen* (1843–47). As a result of his journey to Portugal, he compiled, with Hoffmansegg, *Flore portugaise* (1809–40).

LIN′KAGES (from *link*, AS. *hlence*, Swed. *länk*, Norw. *lænk*, link; connected with OHG. *hlanca*, *lanca*, provincial Eng. *lank*, groin, and probably with AS. *hlanc*, Eng. *lank*, slim). A system of segments or links pivoted together and capable of moving so as to describe various curves; e.g., Watt's parallel motion (1784) employed in beam engines is a case of a link motion in which the outer extremities of the end links are fixed and the mid point of the middle link approximately describes a straight line. Roberts and Tchebichev improved Watt's instrument by varying the form of the links, but Peaucellier (1864) was the first to produce an ideally straight line. His linkage known as Peaucellier's cell consists of seven links as shown in the figure. *A*, *B*, are the fixed points, and *P* is the tracer which moves in a straight line. This achievement is not only of interest to the mathematician, but is of great use to the engineer in securing parallel motion. Sylvester invented the *plagiograph*, or skew pantagraph, which not only reproduces a drawing to a desired scale, but turns it through any desired angle. Hart's contraparallelogram and Kempe's angle trisector are other important linkages. Consult Kempe, *How to Draw a Straight Line* (London, 1877). For the mathematical theory of linkages, consult "Sur les systèmes de tiges articulées," in *Nouvelles Annales*, pp. 520–560 (1875).



LINKÖPING, lȇn′kjẽ′pĭng. An episcopal city of Sweden, capital of the Lăn of Ostergötland, situated on the Stångå, which here flows into Lake Roxen, 110 miles southwest of Stockholm (Map: Sweden, F 7). It is regularly built, with fine parks and public squares; its cathedral, begun in 1150 and restored between 1871 and 1882, is one of the most beautiful in Sweden. The sixteenth-century castle, recently restored, is the residence of the governor of the province. It also possesses one of the largest libraries in the country, and several higher educational institutions. The town manufactures chiefly tobacco. Pop., 1901, 14,552; in 1912, 23,613. Linköping has been an important town since the early Middle Ages. In 1598 it was the scene of the defeat of the Catholic forces of Sigismund of Poland by his uncle, later Charles IX, and the city was the scene of the terrible vengeance exacted by the victors, known in Swedish history as the "Linköping Blood Bath."

LINLEY, lĭn′lĭ, THOMAS (1732–95). An English composer, born at Wells. Upon finishing his studies he settled in Bath, teaching music and giving concerts, at which the principal attraction was the singing of his two daughters. Later he removed to London. The success of Sheridan's *The Duenna* in 1775 was largely due to the music of Linley, and the following year the two formed a partnership and purchased an interest in the Drury Lane Theatre, Linley having direction of the musical interests, which position he held for 12 years. He was also a well-known composer of ballads and madrigals. His death occurred in London.

LINLITHGOW, lĭn-lĭth′gō, or West Lothian. A county in the southeast division of Scotland, bounded north by the Firth of Forth, and having the counties of Mid-Lothian, Lanark, and Stirling on the east, south, and west, respectively (Map: Scotland, E 4). Its area is 120 square miles. Agriculture is in a very advanced state, oats, barley, and wheat being the chief crops. The minerals are of considerable value, and there are several collieries in profitable operation. There are several flourishing ironworks and blast furnaces, fire clay and shale oil are worked, and there is a considerable quarrying industry. There are two royal burghs—Linlithgow, the county town, and Queensferry. Pop., 1801, 17,850; 1901, 65,700; 1911, 79,456.

LINLITHGOW. The capital of Linlithgow County, Scotland, 16 miles west of Edinburgh (Map: Scotland, E 4). It is one of the oldest towns in Scotland and has the parish church of St. Michael's, a beautiful specimen of late Scottish Gothic, adjoining Linlithgow Palace. The palace, strikingly situated on an eminence, was a residence of the Scottish monarchs, and the birthplace of Mary, Queen of Scots, and of her father, James V. The earliest record of its existence is of the time of David I (1124–53), and fragments of various ages are easily detected. Linlithgow was conspicuous in the history of Scotland, and here the Regent Murray was murdered in 1570. Linlithgow owes much to the Knights Templar, whose chief Scottish priory was situated at the adjacent village of Torpichen. A curious tower-like edifice near the railroad station is still pointed out as being a residence of the Knights. Pop. (burgh), 1901, 4279; 1911, 4002. Consult Waldie, *History of Linlithgow* (3d ed., Linlithgow, 1879).

LINN. Various species of the genus *Tilia*. See Lime Tree.

LINNÆAN SOCIETY. See Linnean Society of London.

LINNÆITE, lĭ-nē′ĭt. A sulphide of cobalt which also contains some nickel. It occurs in isometric crystals with other nickel and cobalt minerals.

LINNÆ′US, Carolus (1707–78). The generally used Latin name of Carl von Linné, the great Swedish naturalist, who is chiefly thought of as the originator of the modern nomenclatorial methods as applied to plants and animals, but is to be regarded in a broader sense as the forerunner of the modern systematists.

He was born in Råshult in Småland, Sweden, May 13 (old style; May 23, new style), 1707. His father, Nils Linnæus, was at that time a Lutheran vicar, who in 1709 became pastor. His mother was Christina Brodersson, daughter of the previous incumbent in the pastorate. The antecedents of Linnæus thus account for the desire which prompted and directed the efforts of his parents, in spite of their narrow circumstances, to give him the proper education for the ministry. Nevertheless it would seem that Nils Linnæus unconsciously gave a trend to the young mind of his first-born which may account for the direction which it afterward took in the man; for the pastor was an intelligent gardener, partly for the love of it and partly from necessity, and Linnæus wrote of his father: "He was an uncommon lover of rarities, and had a select garden of uncommon plants."

When the future naturalist was four years of age, it appears that, in spite of his tender years, he was unusually inquisitive in regard to plants. When he reached the age of eight he was assigned a garden spot of his own, and showed much energy in implanting all manner of wild growths. Certainly within these early childish years Linnæus had begun his course as a naturalist; for his love of collecting and habits of observation did in his case what they have in many another—they absorbed his real interest, while his regular tasks were performed more or less perfunctorily. It was fortunate for the boy's peace of mind that his first schoolmaster, Lannerus, in the school at Vexiö, to which he was sent in 1717, was himself fond of botany and encouraged the boy in his botanizing. After seven years of the Gymnasium he passed into the college in the same town, but his academic behavior so ill satisfied his father that he became disturbed for the young man's future. Though Linnæus expressed his willingness to conform to his father's wishes and enter the ministry, he pleaded that he should be allowed to follow his own inclination. The father, however, urged by others who regarded Linnæus unfavorably, determined to apprentice him to a tradesman. From this fate, however, he was rescued through the intercession of Rothmann, a physician of the town of Vexiö, who, recognizing Linnæus' industry and ability, directed his studies in physiology and supplied him with books on botany and medicine. Rothmann, in whose house he was at that time living with his father's consent, had the rare experience of bringing a young man to his life work; and this circumstance illustrates most strikingly the wisdom of directing the young mind into its natural channels. After being with Rothmann, Linnæus went (1727) to Lund, where he furthered his studies under Dr. Kelian Stobæus for a year, after which he went, on Rothmann's advice, to Upsala, where the renowned Rudbeck was teaching. Stobæus seems to have been offended at this, since he was not consulted in regard to the change. The young man arrived at Upsala with little money, and no prospect of self-support, which was the first consideration. While in this state of uncertainty he was one day examining plants in the garden of the university, when Dr. Celsius, a physician and botanist, met him, and shortly afterward engaged him as an assistant in compiling a treatise on the plants of the Bible (*Hierobotanicon*), giving him a home in return, and by recommendations enabling him to get opportunities to give private instruction. While with Celsius he became interested in Vaillant's *Sermo de Structura Florum* (Leyden, 1718) and in Wallin's *Gamos Phyton* (Upsala, 1729), the study of which led him to the writing of an essay on the sexes in plants. This essay served to recommend him to Rudbeck, to whom he was favorably introduced by Celsius. This introduction led to his appointment as Rudbeck's adjunctus, at the same time being appointed to direct the garden in which he would gladly have become a gardener the year previous.

On May 12, 1732, he set out on an exploration of Lapland, carrying his whole outfit on his back. The cost of the journey ($125), which covered upward of 5000 miles, was defrayed by the Academy of Sciences of Upsala. His botanical results were published in his *Flora Lapponica*, which appeared five years later. An account of this journey is contained in the *Lachesis Lapponica*, which was translated in

1811 by J. E. Smith, the first president of the Linnean Society of London, by whom also the Linnæan collections and library were purchased in 1783. On his return from Lapland he made a scientific journey through Dalecarlia at the invitation of the Governor. While at Falun, where he attracted large numbers of people to some public lectures, he met the woman who afterward became his wife, viz., Sara, the daughter of Dr. Moré (Moræus), under whose patronage he went to the Netherlands to study for his degree in medicine. This he received in 1735 at Harderwijk. It was in this year that Linnæus published his *Systema Naturæ*, it being sent to the press at the expense of Dr. Gronovius, who at once recognized its value. This paper, the first edition of which consisted of eight folio sheets, ran through 12 editions, at the same time being expanded.

After obtaining his degree he came under the patronage of George Clifford, a banker of Amsterdam, who had a large garden at his estate, De Hertenkamp. His studies of Clifford's plants appeared as the *Hortus Cliffortianus*. Linnæus stayed in Holland till 1739, and during his residence here wrote, besides the works mentioned above, his *Fundamenta Botanica*, *Bibliotheca Botanica* (both 1736), *Critica Botanica*, *Genera Plantarum* (both 1737), and his *Classes Plantarum* (1738). During this time also his scientific and influential acquaintance and his reputation increased very widely, so that, on prosecuting a journey to France and England, he received considerable, though in different places unequal, attention and recognition.

Returning to the Netherlands, he spent some time in the garden of Van Royen in Leyden. After his recovery from an illness through which he was tended by Clifford, he settled down to the practice of medicine at Stockholm, where, being comparatively unknown, he had little practice. He gained at length the appointment of naval physician (1739), and was at this time enabled to marry. He was honored in Stockholm by the presidency of the academy. In 1741 he was appointed professor of medicine in the University of Upsala, at which time also Rosén was appointed to the chair of botany. During this year Linnæus made a scientific tour of Oland and Gothland, the scientific results of which were published as "Oländska och Gothländska Resa" in 1745. In this paper popular names were first used. In the year following, 1742, Linnæus and Rosén exchanged their offices to their mutual advantage and satisfaction, and this circumstance marks the beginning of his career as teacher and student, which was free from care and uncertainty, and in which he reaped the reward of his previous diligence and perseverance. Until 1778, a period of 37 years was spent in teaching, study, and writing. Students crowded to the university to hear him; the many whom he won to the science of natural history went all over the earth in search of materials, and specimens poured into his hands from all quarters. His reputation became unique and world-wide. During this time, in addition to the revised editions of his previously published works, he wrote the famous *Philosophia Botanica* (1751), *Flora Suecica* (1745), *Fauna Suecica* (1746), *Hortus Upsaliensis* (1748), and the *Species Plantarum* (1753), in addition to other papers on Materia Medica. His *Philosophia Botanica*, and especially his *Species Plantarum*, have been truly regarded as epoch-making, as may be judged from the fact that in 1892 the systematic botanists in convention at Rochester formally adopted the date of publication of the *Species Plantarum* as the starting point for modern nomenclatorial rulings. The Linnæan system is still widely used in the schools of Germany, although superseded by more natural systems for general uses.

In 1761 he received the title of nobility, dated back to 1757, and was thereafter known as Carl von Linné. In 1767, at the age of 60, his remarkable memory began to fail. From 1774 to the time of his death, on Jan. 10, 1778, he suffered greatly as the result of apoplexy, having had no use of his right side for two years before he finally succumbed. He was buried in the cathedral at Upsala.

It is impossible within the limits of a brief biographical sketch to do justice to this great man, for he more than any other has influenced modern systematology. He was the first to use a binomial nomenclature, although his use of it did not correspond to the present method. With Linnæus the specific name stood in the margin and had indexical value, while the generic name stood at the head of the description. His descriptions were stripped of all unnecessary words, and under his skill became terse diagnostic statements of pertinent characters. The system, which consisted in the classification of plants according to the number of stamens and pistils, was avowedly artificial, but was used by Linnæus to get order out of chaos.

Bibliography. For the Linnæus jubilee (1907) many contributions to the literature on the botanist were published: T. M. Fries, *Linné, Lefnadsteckning* (2 vols., Stockholm, 1903), the main work on Linné's life; O. Levertin, *Carl v. Linné* (ib., 1906); J. M. Hulth, *Bibliographia Linnæana* (Upsala, 1907); O. Hjelt et al., *Carl v. Linné's betydelse såsom naturforskare och läkare* (ib., 1907; Ger. trans., 1908).

LINNÉ, lĕn'nå, Carl von. See Linnæus, Carolus.

LINNÉ, P. J. See Lenné, P. J.

LINNE'AN SOCIETY OF LONDON. A British scientific society, founded in February, 1788, by Sir James Edward Smith, a leading botanist, who bought from the executors of Linnæus his library, manuscripts, and natural-history collections. It was incorporated by royal charter in March, 1802. The society annually awards a gold medal, alternating between a botanist and a zoölogist. The papers read at the fortnightly meetings are published in expensive illustrated quarto "Transactions" and octavo "Journals." The headquarters of the society are at Burlington House.

LIN'NELL, John (1792–1882). An English landscape and portrait painter and engraver. He was born in London. At the age of 12 he became a pupil of Benjamin West, and later entered John Varley's studio, where he learned more from Mulready, a fellow pupil, than from his master. In 1805 he entered the schools of the Royal Academy. During the early part of his career he painted good portraits, numbering among his sitters Thomas Carlyle and other celebrated contemporaries. But it was in landscape work that he won renown. He at first preferred glowing sunset and cloud effects, but his later work shows the influence of the Pre-Raphaelites in minute detail. His pictures are, for the most part, in public and private collections of England. In the Tate Gallery, London, are his "Wood-Cutters," the "Windmill," "Noonday Rest," and three others; in the South Kensington Museum, "Wild Flower Gatherers," "The Harvest Moon," and others; in the Metropolitan Museum, New York, "The Monarch Oak." He also painted biblical subjects (chiefly interesting however as landscape studies), such as "Christ's Appearance to His Disciples on the Road to Emmaus" and "Eve of the Deluge." He also executed many miniatures on ivory, and was an engraver of some note. His two sons, James Thomas and William L., also landscape painters, inherited much of their father's talent. Consult Story, *John Linnell* (London, 1892).

LIN′NET (AS. *līnete*, OF., Fr. *linot*, linnet, from Lat. *linum*, flax; so called from their feeding on flaxseed). A finch of the genus *Linaria*, or some near relative. The size is small, the tail forked, and the colors brown mixed with white, and more or less flushed with crimson, especially in the spring dress of the male. All belong to northerly regions. The linnet (*Acanthis*, or *Carduelis*, *cannabina*) is well known through Europe and northern Asia. In its winter plumage its prevailing color is brown, the quill and tail feathers black with white edges; in the nuptial plumage the crown of the head and the breast are bright vermilion color, and a general brightening of color takes place over the rest of the plumage. This change of plumage causes it to be designated by fanciers as brown, gray, or rose linnet, according to the season of the year and the sex. It is the *lintie* of the Scotch. The sweetness of its song makes it everywhere a favorite. It sings well in a cage, and readily breeds in confinement, but the brightness of the nuptial plumage never appears. The linnet abounds chiefly in somewhat open districts, and seems to prefer uncultivated and furze-covered grounds. Its nest is very often in a furze bush or hawthorn hedge, and is formed of small twigs and stems of grass, nicely lined with wool or hair; the eggs are four or five in number, pale bluish white, speckled with purple and brown. Linnets congregate in large flocks in winter, and in great part desert the uplands and resort to the seacoast. In the eastern United States the name is sometimes given to the redpolls (q.v.) and to the purple finch (*Carpodacus purpureus*), a handsome bird over 6 inches long. The male in full plumage has the head and anterior parts of the body rose purple, in the same manner as the true linnet. The female is plain brown, much streaked. See House Finch; Pine Finch; Cage Birds, with the illustrations and authorities cited thereunder.

LINO′LEUM (Neo-Lat., from Lat. *linum*, flax + *oleum*, oil). A peculiar preparation of linseed oil in which the latter is so treated that it becomes solid. The floor covering known as linoleum is made by mixing the linoleum cement made from oxidized linseed oil with various gum resins, ground cork, and pigments, or "fillers." According to the Walton process, the linoleum cement is prepared by pouring successive layers of boiled linseed oil over a thin cotton fabric called *scrim*, which is allowed to dry thoroughly between the applications of the oil. The operation of drying takes about 24 hours, and the oil is applied daily for six or eight weeks. By this time the oxidized oil is about one-half an inch thick and is called a skin. These skins are cut down and ground between rollers and then thoroughly mixed with resin and kauri gum. According to the Parnacott process, also used extensively, the oil is thickened by heating it, while a current of air is continuously blown through it. In this way in from 15 to 18 hours the oil can be oxidized, thickening to a spongy mass, relatively free from stickiness at the end. This is mixed with the resin, as before mentioned. The powdered cork is next added, and if the linoleum is to be plain, coloring matter is also added. This mixture is then applied to jute burlap and the fabric passed between rollers to even off the surface. The pattern is printed in the same manner as upon oilcloth (q.v.), or for inlaid linoleum, tessera of different colored composition are pieced together and rolled with heated rolls. The latter is far better, as the pattern is retained as long as the fabric endures. Consult *History and Manufacture of Floor Cloths* (New York, 1898); *Drying Oils, Boiled Oils, and Solid and Liquid Driers, etc.*, by Lord Edgar Andés (London, 1901); J. I. Lewkowitsch, *Chemical Technology and Analysis of Oils, Fats, and Waxes* (4th ed., ib., 1909); J. G. MacIntosh, *Manufacture of Varnish and Kindred Industries*, vol. i (2d ed., ib., 1904–11). See Lincrusta Walton.

LINOTYPE, lĭn′ō-tīp. See Typesetting Machines.

LIN′SANG (East Indian name). 1. A small, catlike viverrine or civet (q.v.) of the genus *Prionodon* or *Linsang*, inhabiting the Oriental region. The claws are quite retractile, and the feet furry, like a cat's; and there is no second upper molar. Three species exist in the Malay Peninsula and islands, of which *Prionodon particolor* is best known. It is grayish, profusely marked with large black spots and stripes. It is equally at home in trees or on the ground; feeds principally upon birds; and bears two young, once in six months, in a den in a hollow tree.

2. A very similar animal (*Poiana poënsis*) of Fernando Po, West Africa. This animal, however, resembles a genet in behavior.

LIN′SEED (AS. *līnsæd*, flaxseed, from *līn*, flax + *sæd*, seed). The seed of the *Linum usitatissimum*, or flax plant. In America flax is grown almost wholly for the seed. It is chiefly raised in the Northwest, where it is sown broadcast in the spring on new land, or drilled in on old land for wheat or oats. It is harvested and threshed by machinery. (See Flax.) The seed is raised for the oil. Linseed oil is obtained in two ways—by hot pressure and by extraction with naphtha or other solvents, the latter process being the more complete and commonly employed at present. An important by-product of both processes is the residue known as oil cake, which in America is ground and sold as linseed meal. It is a very rich and valuable feeding stuff for animals and is exported extensively. The ordinary linseed oil of commerce is an amber-colored liquid, of a disagreeable taste and odor, largely used in the manufacture of paints, varnishes, and in oilcloth, linoleum, and similar fabrics. When boiled, either alone or with white lead or litharge, it dries much more rapidly on exposure to the air than the unboiled oil. See Oils; Linseed Meal; Oil Cake.

LINSEED MEAL. Often called oil meal in the United States. The residue from the separation of linseed oil from flaxseed. It is of two classes, distinguished as old-process and new-process linseed meal. In the old process the oil is expressed, and the residue is in the form of hard cakes, which are either sold as oil cakes or linseed cake, or ground to a meal. In the new process the linseed oil is more thoroughly removed with the aid of solvents, hence the meal contains less fat, but correspondingly more protein. Both kinds are on the market, but in the United States the product is nearly all the old-process meal. The difference in composition is shown by the following averages: Old-process linseed meal—water, 9.2 per cent; protein, 33.9; fat, 7.9; nitrogen-free extract, 34.4; fibre, 8.9; and ash, 5.7 per cent. New-process linseed meal —water, 10; protein, 37.0; fat, 2.0; nitrogen-free extract, 36.6; fibre, 8.8; and ash, 5.6 per cent.

Linseed meal is a highly prized feeding stuff for calves, fattening cattle, milch cows, horses, and other animals; but on account of its richness it should be fed only in small quantities. A large proportion of the meal produced in this country is exported to Europe.

LINSEED OIL. See Linseed; Oils.

LINT. See Charpie.

LIN′TEL (OF. *lintel*, Fr. *linteau*, from ML. *lintellus*, lintel, dim. of Lat. *limes*, limit). The horizontal beam spanning a doorway, window, or other opening, usually of stone or wood, but sometimes of iron. It is a short architrave, and it may also be cut in the mass in arch shape.

LIN′TERS. See Cottonseed.

LINTH, lĭnt, Escher von der. A Swiss statesman. See Escher von der Linth, Hans Konrad.

LIN′TON, lĭn′ton. A city in Greene Co., Ind., about 40 miles south-southeast of Terre Haute, on the Illinois Central, the Chicago, Terre Haute, and Southeastern, and the Chicago, Indiana, and Louisville railroads (Map: Indiana, C 6). It is in a productive coal-mining region and contains a Carnegie library. Oil and natural gas are found in the vicinity. Linton owns its electric-light plant. Pop., 1900, 3071; 1910, 5906.

LINTON, Eliza Lynn (1822–98). A novelist, wife of William James Linton (q.v.). She was born at Keswick, Cumberland, England, Feb. 10, 1822. A series of papers contributed to the *Saturday Review*, under the title "The Girl of the Period," attracted wide attention. They were collected and published independently in 1883. Mrs. Linton wrote many novels. *The True History of Joshua Davidson* (1872) and *The Autobiography of Christopher Kirkland* (1885) are representative of her best work. She died in London, July 14, 1898. Consult *My Literary Life*, published posthumously (London, 1899), with prefatory note by Beatrice Harraden, and G. S. Layard, *Life of Mrs. Lynn Linton* (ib., 1901).

LINTON, Sir James Dromgole (1840–1916). An English painter. He was born in London and studied at St. Martin's Art School and under Leigh. His early works were in water color, and he did much to spread the interest in that branch of painting. He was president of the Royal Institute of Painters in Water Color from 1884 to 1899 and was elected again in 1909. A fine series of his water colors is in the South Kensington Museum, including "The Student," "The Reliquary," and "Wall Flowers." After 1878 he worked chiefly in oils, and his subjects were mainly genre or historical. They are simply composed, with technical precision, yet charmingly delicate and fresh. Among the best are: "The Marriage of the Duke of Albany" (1885); "Maunday Thursday," and "Boccaccio: The Opening Scene of the Decamerone" (1900), a fine specimen of his decorative ability. He was knighted in 1885 and received various other distinctions. He wrote *Constable's Sketches in Oil and Water-Color* (1904).

LINTON, William James (1812–97). An Anglo-American wood engraver, author, and political reformer, born in London, Dec. 7, 1812. He learned engraving from G. W. Bonner, to whom he was apprenticed in 1828. In 1842 he became the partner of John Orrin Smith, a distinguished wood engraver, with whom he was employed on the *Illustrated London News*. As a young man, he was a zealous Chartist and continued through life a stanch defender of republicanism and the rights of workmen. To promulgate his ideas he founded, with Thornton Hunt and George Henry Lewes, the *Leader*, a daily (1850) which he abandoned because it was not sufficiently radical. He was a friend of Mazzini, the Italian patriot, whose views he expounded in the *Red Republican*. In 1852 he started the *English Republic*, a monthly magazine aiming to explain republican principles. He also contributed articles on social questions to the *Nation* (an Irish patriotic paper), the *Westminster Review*, the *Examiner*, and the *Spectator*. In the middle of the century Linton's reputation as the best English wood engraver of his day was established, and posterity has confirmed the verdict. He did much work as a book illustrator, in which capacity his engravings for the Moxon illustrated Tennyson are representative. In 1858 Linton married Eliza Lynn (see Linton, Eliza Lynn), and it is her book on the Lake country that he illustrated. The marriage proved uncongenial, and the couple amicably parted. A brief visit to the United States (1866) resulted in his finally settling there for the rest of his life, which was thenceforth mainly devoted to the regeneration of wood engraving in America. With his children he settled near New Haven, Conn., set up a printing press, began a most important activity as an engraver, and formed a circle of disciples. Following the traditions of Bewick (q.v.), he championed the use of the white line and legitimate wood engraving (q.v.), as against the manipulative skill of the American school and the new methods of photographic reproductions. Out of Linton's study and practice of his art came *Practical Hints on Wood Engraving* (1879), *A History of Wood-Engraving in America* (1882), *Wood Engraving: A Manual of Instruction* (1884), and *The Masters of Wood-Engraving* (1890)—works as admirable from the practical as from the literary and scholarly point of view. Among his books highly prized by bibliophiles is *The Golden Apples of Hesperus*, a group of little-known sixteenth and seventeenth century lyrics. His other works include: *James Watson: A Memoir of Chartist Times* (1879); *Poems and Translations* (1889); lives of Thomas Paine (1891) and Whittier, in the "Great Writers Series" (1893). Consult his autobiography, *Memories* (London, 1895), and G. S. Layard, *Life of Mrs. Lynn Linton* (ib., 1901).

LIN TSEH-SŬ, lĭn′ tsă′-sōō′ (1785–1850). An able Chinese high official who attained international reputation as "Commissioner Lin." He was born in the Province of Fukien and until he was 17 years old assisted his father as a maker of artificial flowers. Aided by a wealthy friend, whose daughter he married, he became a student, successfully passed the different examinations leading to the doctorate, in 1811 received the degree of *Chin-shih*, the highest in China, and was made censor. He rose rapidly through various grades of provincial service, and became Governor-General of Hunan and Hupeh in 1837. Here he suppressed the opium traffic with such vigor that in 1838 he was sent to Canton to deal with the opium situation there. It was his uncompromising attitude against the introduction of opium, which had been declared contraband of war, together with his destruction of $11,000,000 worth of the drug at Canton belonging to foreign merchants, which led to the "Opium War" with Great Britain. In 1839 he became Governor-General of the two Kwang provinces; but as his relations with the British government representatives became more and more unsatisfactory, the Emperor recalled him to Peking in 1841. In 1843 he was banished to Ili (Kulja), where he was engaged in reclaiming marshes and waste lands in various parts of Sungaria and East Turkestan. At the end of 1845 he was recalled, became acting Governor-General of Shenken, Governor of Shansi in 1846, Governor-General of Yunkwei in 1847, and on the outbreak of the Taiping rebellion in Kwangsi was made acting Governor of that province. Three years afterward, while on his way to attack the rebels, he died. A patriot of ability, but lacking in statesmanship, he was opposed to the opening of the country. Feeling the need of a better knowledge of foreigners, he collected much material for a geography of the world. This was given to another hand, also antiforeign, and in 1844 his great *Geography* was published in 50 books.

LI'NUM (Lat., flax). A genus of plants belonging to the family Linaceæ and containing about eight species, distributed through temperate and warm regions. By far the most important species is *Linum usitatissimum*, whose stems yield flax fibre (linen), and whose seeds yield linseed oil. It is a European species, but cultivated in this country, and is occasionally spontaneous in fields and on roadsides. The characteristic American species is *Linum lewisii* (prairie flax), occurring on the prairies of Dakota and ranging southward to Texas and Arizona and northwestward even to Alaska. This Western flax was for a long time confused with *Linum perenne*, a European form which it closely resembles. A common garden annual, *Linum grandiflorum* (flowering flax), somewhat resembles a single-flowered pink and is one of the few species of flax with red flowers.

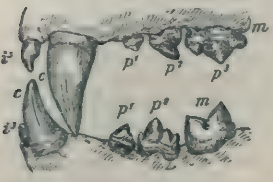
LI'NUS (Lat., from Gk. *Λινος*). A personification of lamentation, called the son of Apollo and a muse (e.g., Calliope, q.v.) or of Amphimarus and Urania. He was the subject of various legends, especially at Argos and Thebes: in one story, the Theban, he was a wonderful musician, the inventor of the Linus song, a song to which special music was appropriated, sung first in Asia Minor, later in Greece. He is said to have been slain by Apollo for contesting with the god in music. Linus was worshiped near Mount Helicon with annual sacrifices and dirges (*lini*). A later story declares that this Linus or a later Linus was teacher of music to Hercules and that, when he rebuked Hercules for dullness, the latter killed him. Linus has been explained as a representative of the tender vegetation destroyed by the summer heat. Thus, Frazer identifies Linus with Adonis and makes the Linus song the lament of the reapers over the dead grain spirit. Consult: H. K. Brugsch, *Die Adonis Sage und das Linoslied* (1859); J. G. Frazer, *The Golden Bough*, vol. ii (2d ed., London, 1911); Mannheim, *Wald- und Feldculte*, vol. ii.

LI'NUS, SAINT. Second Bishop of Rome (67–?79). Irenæus (*Adv. Haer.*, iii, 3), in the latter half of the second century, says that "Peter and Paul, when they founded and built up the Church of Rome, committed the office of its episcopate to Linus," to whom Paul sent greetings (2 Tim. iv. 21). Eusebius, in the first half of the fourth century, followed by Theodoret in the fifth, states that Linus became Bishop of Rome after the death of Peter. Tertullian, Jerome, and others, however, make Clement follow Peter as Bishop of Rome.

LINZ, lĭnts. The capital of the Crownland of Upper Austria. It is situated in a pleasant district on the right bank of the Danube, which is crossed by an iron bridge, connecting Linz with Urfahr, 117 miles by rail west of Vienna (Map: Austria-Hungary, D 2). It is a strongly fortified town with two suburbs, Lustenau and Waldegg. It has several fine squares and monuments, a seventeenth-century cathedral, a cathedral begun in 1862, a municipal parish church (1286), a castle now used as an armory, the episcopal residence, the state theatre, and a museum, with a library. Linz manufactures locomotives and other machinery, lamps, heavy bells, matches, dyes, lacquer ware, woolen goods, lumber, wagons, leather, beer, and tobacco. It has also a shipyard, a state tobacco factory employing 1000 hands, and a chamber of commerce. The city is well supplied with educational institutions and hospitals and has a deaf and dumb institute and a library (50,000 volumes). Steamboats daily ply up the river to Ratisbon and down to Vienna. Pop., 1900, 58,778; 1910, 67,817, mostly German Catholics. Linz was the Roman camp Lentia.

LINZ, AMÉLIE (1824–1904). A German author, born at Bamberg. She married an officer of engineers and four years after his death (1870) settled at Munich. Her literary work, largely under the influence of Paul Heyse, published under the name Amélie Godin, includes the novels *Eine Katastrophe* (1862), *Frauenliebe und Leben* (1874), *Gräfin Leonore* (1882), *Freudvoll und Leidvoll* (1883), *Fahre wohl* (1886), *Mutter und Sohn* (1897), and *Dora Reval* (1901); and several collections of fairy tales, such as *Märchen von einer Mutter erdacht* (4th ed., 1860), *Slavische Märchen* (1879), *Polnische Volksmärchen* (1880), *Grosses Märchenbuch* (4th ed., 1886), *Märchenkranz* (2d ed., 1896), and others.

LION (AS. *lēo*, OF. *lion*, *leon*, Fr. *lion*, It. *leone*, *lione*, from Lat. *leo*, from Gk. *λέων*, *leōn*, lion). The most famous of the great cats (*Felis leo*) and distinguished from all others by its mane and the hairy tuft at the end of the tail. It inhabits Africa and southwestern Asia. A lion of large size stands 3 feet high and measures about 9½ feet from the nose to the tip of the tail, which is about 3 feet long; but most specimens fall short of these figures. The greatest size seems to be attained in South Africa. The weight rarely reaches 500 pounds. The skull of an adult may measure 13 inches in length, and 9½ inches in breadth across the cheek bones. In accordance with its desert life its color is a uniform pale tawny, sometimes reddish and occasionally almost black. Though never streaked or spotted, the mane is frequently darker than the coat or even diversified with blackish patches. Kittens are obscurely spotted and striped at first, as is the case with other concolorous species of groups generally spotted, but this disappears after a few months. The lioness is somewhat smaller than the lion and has no mane—nor have young males. Sometimes they never acquire more than a scanty ornament of this kind, but the so-called "maneless lion of Gujarat" seems not to exist as a separate race. There is, however, great diversity in this feature, as in color, even within the same litter. The mane is evidently a sexual ornament, and also a shield, which offers some protection to the males in the combats which occur in this species more frequently and with more fierceness than in the case of any other wild cat of which we know. The whole frame is extremely muscular, and the fore parts in particular are remarkably powerful, giving, with the large head and copious mane, a noble appearance to the animal, which, with its strength and its appalling voice, has led to its being called the "king of beasts." The accompanying nobility of character which has been ascribed to it by Buffon and his followers seems, however, largely fanciful.



TEETH OF THE LION.

Permanent dentition: *i*, incisors; *c*, canines; *p*, premolars; *m*, molars. In the upper jaw p^3 is the upper carnassial, and in the lower jaw *m* indicates the lower carnassial tooth.

Habitat. In the time preceding the Glacial epoch lions, indistinguishable by their remains, entombed in the floors of caves, from modern forms, roamed over all southern Europe, Germany, France, and the British Isles. They seem to have been exterminated in the north and west by the glacial cold, but survived in southeastern Europe well into historic times, for the Romans knew of them anciently in what is now Rumania, Greece, and European Turkey; and still more recently they have existed in Syria and Arabia. These animals probably were driven away by man. They were also formerly numerous from the Caucasus to Afghanistan and Baluchistan, but are now scarce and local in Asia, extinct in Asia Minor, Arabia, and Egypt, and have nearly or quite disappeared from Algeria.

In Asia they were formerly abundant on the sandy wastes of Rajputana and the high plains of Persia, but now have almost or quite disappeared from India and are confined to the swampy lowlands of the Tigris and Euphrates valleys, and certain valleys east of the Persian Gulf; in Africa they are to be found in the naked deserts of the southern Sahara, the Kalihari Desert, and the Abyssinian regions, as well as among the rough hills of Mashonaland and the dense swamps of the upper Nile tributaries. Everywhere, during the day, they are likely to hide and sleep in secluded clusters of brush-grown rocks, thickets of thorny bushes, or patches of reeds or tall grass with the color of which their yellow coats are perfectly in accord. It is in such haunts and in the spring that the whelps are born. Usually there are three young, and rarely are more than five produced. They are born with their eyes open (the pupils are round). Although during the pairing season the lioness apparently delights in provoking jealous combats for her favors, by which the weaker members of the race are continually "weeded out" and only the strongest survive to produce offspring (see SEXUAL SELECTION), she makes a devoted mother, and the male stays with his family and assists in supplying their wants until the young are well grown. It is said that old lions of unusual strength are often polygamous; and it is also asserted that ordinarily the same mates keep together for several successive seasons or for life. Probably both assertions are true; likely it is also true that other pairs change annually. Where the animals are or were very numerous, polygamy and frequent change of mate would be likely to happen more often than where they were few and the range of choice correspondingly limited. No young lion can get a mate, nor an old one keep her, where others are about, except by fighting.

Where lions have not been much disturbed by guns they are likely to be seen abroad and hunting in the daytime, sometimes in small family troops, but elsewhere, and generally, they prowl and hunt at night. Though able to gallop swiftly for a short distance, their weight and their feline nature incline them to adopt stealthy approach or ambush in their hunting. They are unable to climb trees, but are nimble enough in scrambling about rocks. Knowing the habits of the animals they seek, they wait beside their paths or at their drinking places, or skillfully stalk them in the open, depending as much probably on their eyesight as on their faculty of scent. What they eat depends upon where they live. In India deer, antelopes, wild boars, and lesser wild animals are largely supplemented by domestic or semidomestic cattle, goats, pigs, ponies, camels, and an occasional Hindu. In Mesopotamia the lions would greatly decrease or starve were it not for the large herds of half-wild pigs that range the oak forests east of the Persian Gulf. In Africa their great numbers were correlative with the hordes of game with which that continent was frequently overrun, and the disappearance of this game means the doom of the "king of beasts," unless cattle replace the wild grazers. The elephant, rhinoceros, and hippopotamus are beyond its powers, and the buffalo is able to resist a single lion, as a rule, though frequently pulled down by two or three acting in concert. The larger antelopes and equine animals are the lion's natural and constant prey, and it seems to prefer the latter—the zebras and wild asses. These animals, however, keep in the open plains, are quick to perceive and swift to escape intended attack, and in the days when game was abundant most lions fed mainly on antelopes. Even here, however, they had not always an easy victim. Schulz, who gives an unusual amount of information as to the Central African lion in his *New Africa*, says that this beast does not dare attack roan and Harris's antelopes in his usual manner, a leap from behind to the haunches, "for with their backward sweeping horns they are able to make things lively for any lion foolish enough to make the attempt. These, with hornless game, such as the quagga, they seize by the nose."

The method of attack has been described in so many ways by creditable hunters and native observers that it is evident no one method exists; but if the first lightning-like leap and

overbearing stroke does not crush the animal, the nose may be seized in a paw and the head jerked back, breaking the neck; or the great blood vessels of the throat may be gnawed open, or the animal simply be mauled to death. It is customary for the lion, like other great cats, to carry or drag its prey into a thicket or near its lair before feeding upon it, and under the excitement of being disturbed and chased it is capable of extraordinary feats of strength in so doing, but these seem to have been exaggerated. That he can drag a large animal a considerable distance is undoubted. Having killed his prey, he eats at once what he wants of it. If other lions have helped him, they get what they are able to take. When they are satisfied, any lioness or young lions near by get such shares of what remains as their agility and courage enable them to seize.

Wherever settlements are made in a district infested by lions, these animals profit by raids upon domestic animals; and the scarcer the wild prey becomes, and the more familiarity the lions acquire with man and his ways, the more harm they do. Few fences or stockades are effective against them. The next step is the habit of occasional or persistent preying upon humanity. How the lion of the wilderness behaves in the presence of man depends upon such a diversity of circumstances, and so varies with individuals, that it is not safe to generalize. If he is not hungry and has a free way for retreat, he will very likely run when a man is met; but he may charge on the instant. A few brought to bay have been known to cower, but the majority fight for life bravely. Occasionally certain lions, like tigers, get into the habit of deliberately seeking human flesh. They are often old, weakened ones, no longer capable of hunting well, but sometimes are individuals, wiser than the ordinary, who have learned that humanity is the easiest possible prey. Such animals must be got rid of, and in Africa parties are organized to hunt and kill them—an achievement rarely accomplished without further loss of human life.

The hunting of lions is done nowadays almost altogether on foot, by lying in wait at night at their drinking places or by seeking them by day in their lairs. The literature of sport in Africa, Persia, and India abounds in thrilling tales of adventures thus encountered. Various traps have always been used for their capture, the most successful of which is the pitfall, and by this means principally were captured the great numbers of lions familiar to the civilized people of antiquity. See Hunting Big Game.

This imposing animal, we are told, makes its appearance in art and literature very early. Frequent mention is made of it in the cuneiform tablets and Hebrew Scriptures. In the so-called *Song of Pentaur*, describing the war of Ramses II against the Cheta, lions are said to have accompanied the King's chariot. They were kept in all the Roman cities for the public sports, and hundreds were sometimes provided for the entertainment of the populace in a single series of games. They were pitted against each other, or some other great beasts, but mainly they were matched against the bestiarii, or professional animal killers of the arena. So great and lasting was the demand for this purpose that the supply became scanty, and the Emperor Honorius, in the fifth century, enacted laws prohibiting the killing of African lions. Under this protection they so increased and became so bold in their destruction of villagers and cattle that Justinian was compelled to rescind the edict. Extraordinary stories are told of the degree of tamability and education reached by some of these ancient lions, but they should be received with distrust. The kittens are playful, gentle, and affectionate, and some adults are docile, subdued, and even seem to care for their teachers, but none is really trustworthy; all must be kept in subjection by fear, and their acquired intelligence is very small. The tricks and performances which the trained beasts of the menagerie go through are usually very simple when analyzed. Lions withstand captivity well, however, and finer specimens have probably been reared in zoölogical gardens than ever were seen in the wilderness. They breed readily, even in traveling menageries, and few if any now exhibited were not born in captivity.

For the Asiatic lion, consult authorities mentioned under Tiger. See Colored Plate of Felidæ.

Bibliography. A good account will be found in the *Royal Natural History* (London, 1895; New York, as the *New Natural History*, about 1898). J. H. Porter, *Wild Beasts* (New York, 1894), has a very complete and judicious summary of the animal's biography; while the best recent accounts are Richard Lydekker, *Game Animals of Africa* (London, 1908), and Roosevelt and Heller, *Life-Histories of African Game Animals* (New York, 1914). For the African lion and its hunting, consult the writings of many missionary travelers and hunters, especially David Livingstone, *Missionary Travels and Researches in South Africa* (London, 1857); and Robert Moffat, *Missionary Labors and Scenes in South Africa* (ib., 1845); Gordon-Cumming, *A Hunter's Life in Africa* (New York, 1850); Daumas, *Les chevaux du Sahara* (Paris, 1851); Harris, *Wild Sports in Southern Africa* (5th ed., London, 1852); Gérard, *La chasse au lion et les autres chasses de l'Algérie* (Paris, 1854); Blanford, *Geological and Zoölogical Survey of Abyssinia* (London, 1870); C. J. Anderson, *The Lion and the Elephant* (ib., 1873); W. H. Drummond, *The Large Game and Natural History of South and South East Africa* (Edinburgh, 1875); V. L. Cameron, *Across Africa* (London, 1877); G. Schweinfurth, *Heart of Africa* (Leipzig, 1878); Holub, *Seven Years in South Africa*, translated by Frewer (London, 1881); W. M. Kerr, *The Far Interior* (ib., 1886); F. C. Selous, *A Hunter's Wanderings in Africa* (ib., 1890); Sir S. W. Baker, *Wild Beasts and their Ways* (ib., 1890); Schulz and Hammar, *New Africa* (ib., 1897); Stevenson-Hamilton, *Animal Life in Africa* (New York, 1912); Sir A. E. Pease, *Book of the Lion* (2d ed., London, 1914). One of the most remarkable books on the achievements of maneating lions will be found in J. H. Patterson, *The Man-Eaters of Tsavo* (London, 1908).

LION, lē′ôɴ′, Golfe du. An inlet of the Mediterranean. See Lyons, Gulf of.

LION, Henry the. See Henry the Lion.

LION, Order of the. 1. A civil and military order, founded in 1770 by Landgrave Frederick II of Hesse-Cassel, with one class and 41 knights. In 1818 it was extended to four classes, but has now only one class. It is restricted to members of the grand ducal house and princes. 2. A civil order with three classes, founded in 1815 by William I, King of the Netherlands. The decoration is a white enameled cross with four W's, bearing the motto *Virtus nobilitat* (virtue ennobles) and on the reverse the golden lion. See Plate of ORDERS.

LI'ONFISH'. A gray, yellow-blotched sculpin (*Scorpæna grandicornis*), common among seaweed from Florida to Brazil and on account of its ugly aspect much dreaded by the fishermen.

LION GATE. The entrance to the acropolis of Mycenæ. The gateway, about 10 feet in height and width, is at the end of a walled passage designed to increase the difficulty of an attack. The great gateposts, of single blocks, approach slightly at the top. On them rests a lintel composed of a block 15½ feet long and 8 feet thick. Above the lintel a triangular space is left to distribute the vertical pressure and is occupied by a slab 12¼ feet wide and 10¼ feet high, on which is carved the celebrated relief which gives the gate its name. The middle of the slab is occupied by a column, flanked by two lions, whose hind feet are on the ground, while the forefeet rest on the base of the column. The heads were turned to the front, but are no longer extant. The structure probably dates from about 1180 B.C.

LIONNE, lē'ôn', HUGUES DE, MARQUIS DE BERNI (1611–71). A French statesman, born at Grenoble. He was of a noble family of Dauphiné and was brought up by his uncle, Abel de Servien, under whom he received his first training in diplomacy. Mazarin, then Prime Minister, recognizing Lionne's ability, gave him several important offices. As Secretary of the French Embassy, he was present at the Congress of Münster (1641) and the following year was sent on a mission to the Pope. He was appointed secretary to the Queen Mother, Anne of Austria, in 1646. Afterward he was Ambassador to Spain, Frankfort, and Turin, and as Minister of State, a position he received in 1659, concluded the Peace of the Pyrenees (1659). On his deathbed Mazarin recommended Lionne to the King, and for the next 10 years he had charge of foreign affairs. Among his most important negotiations were the sale of Dunkirk, the Treaty of Breda (1667), and the Treaty of Aix-la-Chapelle (1668). His *Memoirs* and letters are of value as throwing light on the diplomatic relations between France and Europe in the early part of the reign of Louis XIV. Consult Valfrey, *Hugues de Lionne, ses ambassades en Italie, en Espagne et en Allemagne* (Paris, 1877–81), and Chevalier, *Lettres inédites de Hugues de Lionne, ministre des affaires étrangères sous Louis XIV, précédées d'une notice historique sur la famille de Lionne* (Valence, 1879).

LION OF LUCERNE. A memorial at Lucerne, Switzerland, to the 781 Swiss guards who fell on Aug. 10, 1792, in defense of Louis XVI during the attack on the Tuileries. The figure is carved in the face of a cliff and represents a dying lion of colossal size, transfixed by a spear, but defending the lilies of France. The memorial was modeled by Thorvaldsen and was dedicated in 1821. Beneath it are inscribed the names of the 21 officers of the guards.

LION OF ST. MARK. The official device of the ancient Republic of Venice. A winged lion was the emblem of Mark the Evangelist, patron saint of Venice. It was depicted on the Venetian standard and modeled in bronze on one of the columns in the Piazzetta. The bronze was carried to Paris by Napoleon in 1797, but was restored in 1815.

LION OF THE NORTH. A title given to Gustavus Adolphus of Sweden.

LION'S MOUTH (It. *Bocca di Leone*). An opening in the wall of the Sala della Bussola, the antechamber of the Inquisitors, in the Palace of the Doges at Venice. The opening was once adorned with a marble lion's head, the mouth of which served as a channel for secret information and anonymous accusations.

LION-TAILED MONKEY. A macaque (*Macacus silenus*) of western India. It is of medium size, almost black in color and with the end of the comparatively short tail tufted. A large ruff of white hair surrounds the face and neck. This species goes in troops in the forest, is often called wanderoo, and is sulky and intractable in captivity.

LIOTARD, lē-ō'tär', JEAN ETIENNE (1702–89). A Swiss portrait painter, born at Geneva. He studied under Jean Baptiste Massé and Le Moyne in Paris, whither he went in 1723, devoting special attention to pastel. While in Constantinople, where he remained for several years, he portrayed many dignitaries and foreign ambassadors. In 1743 he went to Vienna and thence to Paris and London, everywhere painting the portraits of the great. After his sojourn in Constantinople he adopted the Turkish costume and hence was nicknamed "the Turk." In or about 1756 he visited Holland, was married there, and in 1773–74 was again in England, where he sold advantageously a valuable collection of paintings by celebrated masters. His forte lay in intensely individual and subtle pastel portraits, executed with rare psychological penetration, malicious fantasy, and delicate skill. Among the most celebrated are "Vienna Chocolate Girl" (Dresden Gallery) and Madame d'Epinay (Rath Museum, Geneva). The Amsterdam Museum contains "La belle Lyonnaise" (1746, replicas in Dresden and Vienna), and more than a dozen other portraits, including those of Maria Theresa, Joseph II, Marshal Maurice of Saxony, and Lord Bessborough. He also painted numerous portraits of himself, examples of which are in Dresden and in the Uffizi Gallery in Florence. Consult Humbert, Revilliod, and Tilanus, *La vie et les œuvres de J. E. Liotard* (Amsterdam, 1897), and Baud-Bovy, *Peintres genevois* (Geneva, 1903).

LIOUVILLE, lyōō'vēl', JOSEPH (1809–82). A French mathematician, born at Saint-Omer. He was educated as an engineer at the Ecole Polytechnique, where he became a professor of mathematics in 1833. In 1839 he took up the same duties at the Collège de France and in the same year was admitted to the Academy of Sciences. In 1848 he became a deputy in the Assembly for Meurthe. In 1836 he founded the *Journal de Mathématiques Pures et Appliquées*, better known as the *Journal de Liouville*. He edited Evariste Galois's *Œuvres mathématiques* (1840), Monge's *Géometrie*, and Navier's *Leçons;* and he published also many original *Notes* and *Mémoires*.

LIOY, lē-ō'ē, PAOLO (1836–1911). An Italian naturalist, best known for his studies of the lake dwellers. He was born in Vicenza, studied at Padua, and in 1866 was banished for expressing anti-Austrian sentiments in a newspaper article. He was elected to the Italian Parliament after the Austrian evacuation, took some part in politics, voting with the Moderate Liberal party, and wrote some fictions, biographies of Agassiz and of Darwin, and the following important scientific works: *Di una stazione lacustra scoperta nel lago di Fimon* (1864; 3d ed., 1876); *La abitazioni lacustri della età della pietra* (1865); *Conferenze scientifiche* (1872; 2d ed., 1877); *Sui alghi* (1884); *Escursione nel cielo* (4th ed., 1885); *Linneo, Darwin, Agassiz nello vita intima* (1904); *Apparitions et souvenirs* (1908); as well as other works on alpine climbing.

LIPÁ, lē-pä′. A town of Luzon, Philippines, in the Province of Batangas (Map: Philippine Islands, C 4). It is situated in a mountainous district, 18 miles north of Batangas, on the railroad between that city and Manila. It is also the junction point of three highways. It is a progressive town, the largest in the province, has a large church and good schools and markets, and is an important centre for the sugar, coffee, and tobacco trade. There are manufactures of rough textiles. During February fairs attract many people. Pop., 1903, 37,934.

LIPAN, lē̇-pän′. A little-known Apache tribe, formerly roaming along the lower Rio Grande in New Mexico and Texas. During the Texas Indian wars of 1845 and 1856 they were greatly reduced in strength and driven into Mexico, from whence a few survivors returned to the Mescalero Reservation in 1905. Consult P. E. Goddard, "Indians of the Southwest," in *American Museum of Natural History, Handbook Series, No. 2* (New York, 1912).

LIPARÆ′Æ IN′SULÆ. See LIPARI ISLANDS.

LIPARI, lĭp′ȧ-rĭ *or* lē′pȧ-rē̇ (or ÆOLIAN), **ISLANDS.** A group of seven large and many small islands in the Mediterranean, immediately north of Sicily, between long. 14° 15′ and 15° 15′ E. (Map: Italy, E 5). The larger isles are Lipari, Salina, Vulcano, Filicuri, Stromboli, Panaria, and Alicuri. The total area is about 45 square miles. They are all of volcanic origin, with peaks ranging in height from 1000 to 3140 feet. The islands of Stromboli, Lipari, and Vulcano still contain active volcanoes, Stromboli having been the scene of eruptions in 1902 and 1907, the latter destroying much property. The climate is mild and healthful. In spite of their volcanic nature, mountainous surface, and scarcity of water, the islands are, as a rule, well cultivated, producing wine, currants, olives, figs, other southern fruits, and salt. The largest island, Lipari, yields large quantities of pumice stone and contains hot springs. The group forms a part of the Sicilian Province of Messina. Pop., about 20,000. The town of Lipari, on the east coast of the island of the same name, has a good harbor. Pop., 1911 (commune), 15,616. Consult *Die liparische Inseln* (Prague, 1893).

LIP′ARITE. See RHYOLITE.

LIP′ASE (from Gk. λίπας, *lipas*, λίπος, *lipos*, fat). An enzyme which saponifies fats, i.e., decomposes them into fatty acids and glycerin. Among plants lipase is found in oily seeds when they germinate, and according to the latest work it is present also in such seeds when they are ripening. The synthesis of fats from fatty acid and glycerin is due to the reversible action of lipase. It is especially abundant in such seeds as castor oil, hemp, rape, and flax. It is doubtless also present in other parts of the plant where oil constitutes a reserve food. In germinating seeds the oil gradually disappears, the lipase digesting it and so rendering it available for the nutrition of the young embryo. The precise products of its action are not known. See DIGESTION IN PLANTS; ENZYME.

LIPETSK, lyĕ′pĕtsk. The capital of the District of Lipetsk in the Government of Tambov, Russia, situated on the Voronezh, 107 miles west of the town of Tambov (Map: Russia, E 4). It has manufactures of spirits, sugar, iron, brick, and tallow. There are exports of grain. It has noted chalybeate springs, discovered in 1700 by Peter I and much visited during the season, which lasts from the end of May to August. Pop., 1897, 20,323; 1913, 23,500.

LIPINSKY, lē̇-pĭn′skē̇, KARL JOSEPH (1790–1861). A famous Polish violinist, born at Radzyn. Excepting a little instruction from his father, a talented amateur, he was entirely self-taught. In 1810 he became concert master at the Lemberg Opera, advancing two years later to the post of conductor. He went to Italy in 1817 for the purpose of hearing Paganini. A close friendship soon sprang up between the two artists, which, however, came to a sudden end in 1829, when both appeared in Warsaw. Paganini's vanity could not bear the success of a rival. For the next decade Lipinsky's tours throughout Europe were a succession of triumphs. From 1839 until his retirement shortly before his death he occupied the position of concert master of the Royal Chapel at Dresden, which he completely reorganized and made one of the foremost institutions of Germany. He was famous for his powerful tone and marvelous dexterity in double stopping.

LI PO, lē pō. See LI TAI-PEH.

LIP′OGRAM (from Gk. λείπειν, *leipein*, to leave + γράμμα, *gramma*, letter). A species of verse characterized by the exclusion of a certain letter, either vowel or consonant. The earliest author of lipogrammatic verse was the Greek poet Lasos (born 538 B.C.), who composed an *Ode on the Centaurs* and a *Hymn to Ceres* in which the sigma was lacking. In the third century A.D. Nestor, of Laranda, composed an *Iliad* in 24 books, from each of which, in succession, one of the letters of the Greek alphabet was omitted. Two centuries later, Tryphiodorus, a Græco-Egyptian writer, composed an *Odyssey* on the same plan. Fabius Claudius Gordianus Fulgentius, a Christian monk of the sixth century, performed a similar feat in Latin. In modern times Spaniards and Italians have been most addicted to this laborious frivolity. Lope de Vega wrote five novels, from each of which one of the vowels is excluded; and Orazio Fidele wrote a poem entitled *R Banished by the Power of Love* (1633). In Germany the collection of Burmann, entitled *Poems without the Letter R* (1788), is composed in the same plan. Several French poets have also attempted this *tour de force*. The subject is discussed by Addison in an essay on true and false wit in No. 59 of the *Spectator*. Consult Wheatley's book on *Anagrams* (1862).

LIPO′MA. See TUMOR.

LIPOWITZ' METAL. See FUSIBLE METAL.

LIPPE, lĭp′pe. A principality and constituent state of the German Empire, between the Weser and the Teutoburger Wald, bounded on the northwest, west, and south by the Prussian (Westphalian) Government District of Minden, on the northeast by the Prussian Circle of Rinteln, belonging to Hesse-Nassau, and on the east by the Prussian Province of Hanover and an enclave (Pyrmont) of the Principality of Waldeck (Map: Germany, C 2). The area of Lippe—including its three small exclaves in Westphalia, viz., Kappel, Lipperode, and Grevenhagen—is 1215 square kilometers (469 square miles).

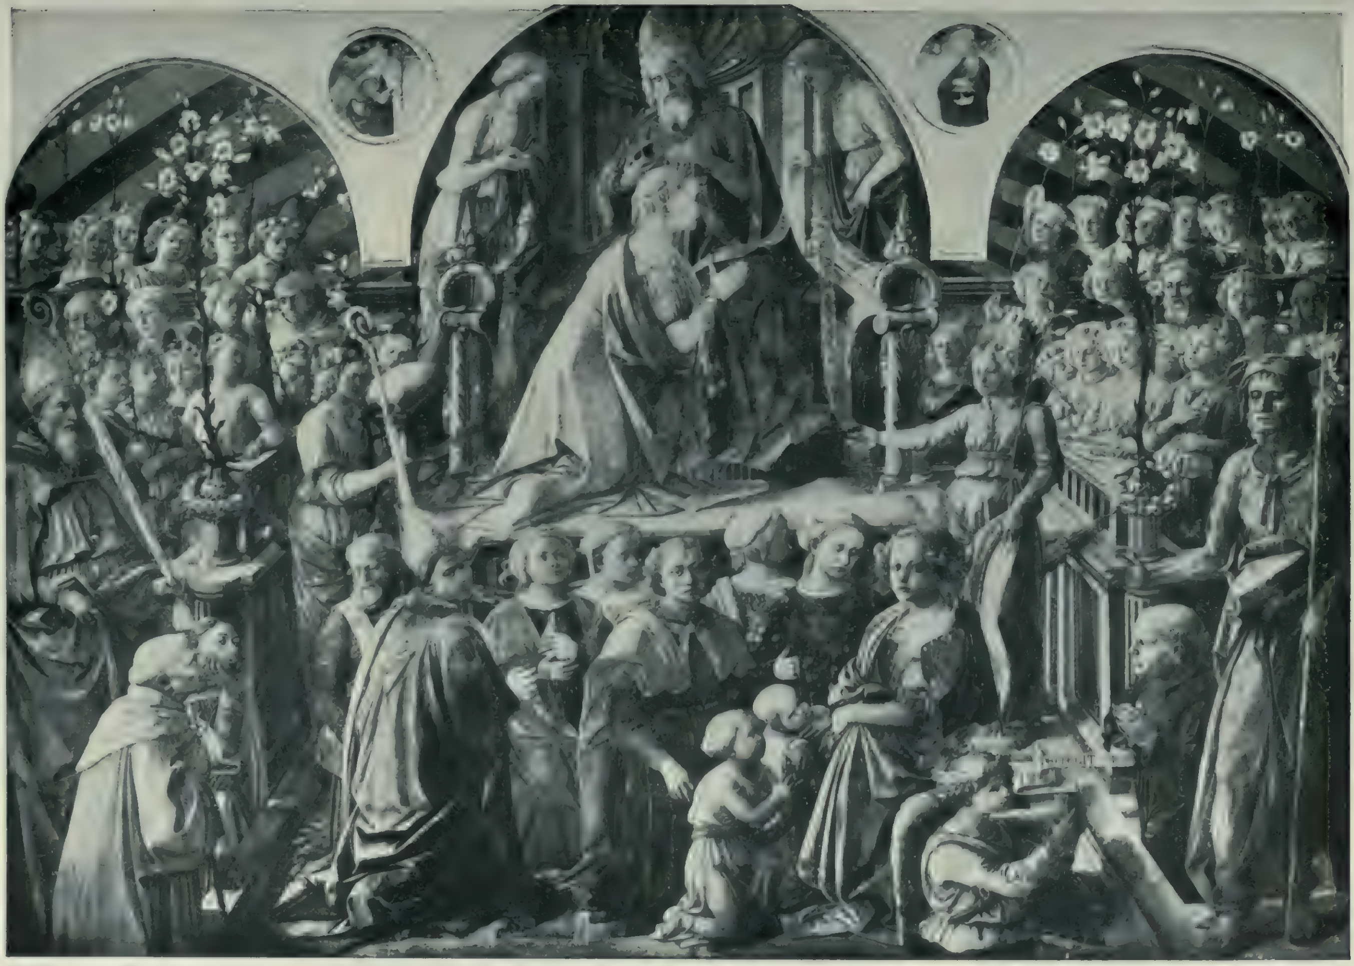
For the most part the surface is hilly, but there are no lofty mountains. The highest elevations are in the southwest, in the Teutoburger Wald, where the Köterberg has an altitude of 1647 feet. Hydrographically Lippe belongs to the basin of the Weser and is watered by the Werre and several other tributaries of that river. The Weser also touches it on the north for a short distance. The climate is moderate and healthful. With the exception of salt, there are practically no minerals in the principality. Mineral springs are found in some parts. The soil is of indifferent fertility, but agriculture is nevertheless the chief occupation. The land is divided principally into medium holdings, which are protected from subdivision by the right of primogeniture. Of the total area of 121,520 hectares, over one-half is under crop. In 1900, 64,500 hectares (53.1 per cent) were arable land; meadows amounted to 8400 hectares (6.9); pastures, 10,500 (8.6); woodland, 33,500 (27.6). In 1913 there were under rye 14,993 hectares; wheat, 6649; oats, 13,830; potatoes, 7450; hay, 7762. Stock raising is of some importance. In December, 1912, there were 10,212 horses, 38,945 cattle, 7793 sheep, 125,992 swine, and 38,768 goats. Lippe is one of the best-wooded parts of Germany; in 1900 woodland amounted to 33,500 hectares (27.6 per cent of the total area). The greater part of the forests, which are largely deciduous, belongs to the state. The manufacturing industries are undeveloped. Yarn spinning and linen weaving are carried on as house industries to a limited extent. The commerce is also of little importance, the principal exports being agricultural and forest products, yarn, and linen. Native artisans, especially brickmakers, go each spring in large numbers to other parts of Germany and even to foreign countries and return in autumn. The principality is traversed by two state railway lines.

Lippe is a constitutional monarchy, the crown being hereditary in the male line. The constitution (of 1836, revised in 1867 and 1876) provides for a Diet of 21 members elected directly for four years, by voters divided into three grades, according to the amount of taxes paid, each grade electing seven representatives. The executive and judicial parts of the administration are vested in the cabinet. There is a Supreme Court at Detmold, the capital, from which appeals are made to the Court of Appeals at Celle, Hanover. Lippe is represented by one member in the Bundesrat and one in the Reichstag. The budget for 1913–14 showed estimated revenue and expenditure of 2,853,000 and 2,616,000 marks respectively. Public debt, March 31, 1913, 1,278,391 marks. Education is well provided for, and the military affairs are in the hands of Prussia. The population increased from 111,135 in 1871 to 128,495 in 1890, 138,952 in 1900 and 150,937 in 1910 (census of December 1), the increase in the last decade being 8.3 per cent. Of the 217 communes, 208 in 1910 had each less than 3000 inhabitants, or altogether 99,846; and 9 had over 2000 each, or a total of 51,091. The population of Detmold was 14,295. The number of Evangelicals in 1910 was returned at 143,961 (95.38 per cent); Roman Catholics, 5936 (3.93); Jews, 780 (0.52).

History. The Principality of Lippe first appears as an independent country in 1123. Its history was uneventful. In 1807 it joined the Confederation of the Rhine. In 1836 a constitution was promulgated, and the country joined the German customs union. As in most of the German states, its ruler, Prince Paul Leopold Alexander, had to promulgate a new constitution in 1848, but his son Leopold, who came to the throne in 1851, reëstablished in 1853 the old constitution. In the War of 1866 Lippe took the side of Prussia and joined the North German Confederation. In 1871 it became a part of the German Empire. Since then the only disturbing factor has been the conflict regarding the succession which has raged between the houses of Lippe-Biesterfeld and Schaumburg-Lippe. In 1904 the two contending houses decided to submit the question to a court of arbitration. In October, 1905, the court decided in favor of the Lippe-Biesterfeld branch, and Leopold IV (1871–) was made sole ruler of the principality. Consult Schickedanz, *Das Fürstentum Lippe-Detmold* (Hildesheim, 1830), and Triepel, *Der Streit über die Thronfolge im Fürstentum Lippe* (Leipzig, 1903).

LIPPE-SCHAUMBURG, shoum′bụrk. A principality of Germany. See SCHAUMBURG-LIPPE.

LIPPI, lĭp′pė, FILIPPO. The name of two of the foremost Florentine painters of the early Renaissance; the younger is usually called Filippino Lippi. They are known also by the Florentine forms of their names, "Lippo" and "Lippino." Fra FILIPPO (c.1406–69), the father, was the son of a butcher of Florence. His parents died soon after his birth and he was cared for by his aunt Lapaccia, who placed him at the age of eight in the convent of the Carmelites. He scribbled his books with drawings instead of learning from them, and the good and sensible prior yielded to Filippo's wish to become a painter. In 1431, probably with the consent of the brethren, he left the convent for a wider field of activity, but without renouncing his order; for his death is duly recognized in its necrologies. Although he soon obtained the patronage of Cosimo de' Medici, he was usually in trouble, and it required more than once the powerful influence of the Medici to deliver him from the lawsuits and tribulations into which his improvidence and other faults plunged him. In a letter of 1439 to Pietro de' Medici he calls himself the poorest friar in Florence, and begs for a loan to aid him in support of six unmarried nieces. Through the influence of the Medici he received ecclesiastical preferments—among others to be abbot and perpetual rector of San Quirico at Legnaia, near Florence. From this benefice he was removed for forgery and other offenses. In 1452 he received a commission to decorate the chapel and paint the high altar of the cathedral of Prato. In 1455 he bought a house at Prato, and in 1456 he was appointed chaplain to the nunnery of Santa Margherita. He had before this become infatuated with Lucrezia Buti, a nun, who served as the model for St. Margaret in his Madonna della Cintola (Prato Gallery), an altarpiece painted for the nuns. In 1456 Filippo abducted her to his house at Prato, where she was joined by her sister Spinetta and three other nuns. But in 1458 the five returned penitent to the convent, and were in 1459 received back as nuns. Yet Filippo was not deprived of his chaplaincy till 1461. Cosimo de' Medici, to whom he appealed for aid, obtained from Pope Pius II a special brief releasing Filippo and Lucrezia from their monastic vows and allowing them to



FRA FILIPPO LIPPI

"THE CORONATION OF THE VIRGIN." FROM THE PAINTING IN THE ACADEMY OF FINE ARTS, FLORENCE

marry. In 1467 Filippo removed to Spoleto to execute an important commission, the frescoes of the choir of the cathedral, a task which he did not live to finish. He died suddenly Oct. 9, 1469, and was buried in the cathedral, where a stately marble tomb was erected by Lorenzo the Magnificent to contain his body. Vasari's story that Filippo was poisoned entirely lacks confirmation.

As a painter Filippo Lippi ranks highest among the followers of Masaccio, whose pupil he may have been; for the epoch-making frescoes of the Brancacci Chapel were painted for his own convent when Filippo was an inmate. His works, however, show the influence of an earlier Giottesque master, possibly Lorenzo Monaco (q.v.), and reflect the idealism of Fra Angelico. They are warm and transparent in color and are full of human sympathy. Filippo possessed an illustrative talent of the highest order and an unfailing good humor. He was the first to paint a class of pictures characteristic of the Florentine school, in which the Virgin is portrayed as a Florentine mother, and maternal love and childish innocence are the themes represented. His greatest surviving works are the frescoes in the cathedral of Prato (1452–64), which are worthy of comparison with those of Masaccio in the Brancacci Chapel. They represent scenes from the lives of John the Baptist and St. Stephen. Although he is inferior to Masaccio in composition and simplicity, and though he places too much emphasis on subsidiary figures, Fra Filippo excels in individual figures and in the delineation of costume. The frescoes in the apse of the cathedral of Spoleto, representing the life of the Virgin, are the most mature of his works. The grandiose design is by Filippo, but the execution is chiefly the work of his assistant and pupil, Fra Diamante, an inferior artist.

Filippo shows to best advantage in his easel pictures. Among the very best of these is the famous "Coronation of the Virgin," painted in 1441 for the nuns of San Ambrogio, now in the Florentine Academy. This collection, which is richest in his works, possesses also a fine "Madonna with Saints," as does the Louvre; there are charming madonnas in the Berlin Museum, the galleries of Munich and Prato, the Pitti Palace, and the Uffizi, the last mentioned being particularly famous. In the National Gallery, London, are the "Vision of St. Bernard" (1445) and an "Annunciation"; in the Berlin Museum, the "Virgin Adoring the Infant" and "Mary, Mother of Mercies," in which the Virgin is represented with large numbers of kneeling worshipers under her wide-spreading mantle, on either side. The Lateran Gallery (Rome) possesses a "Coronation of the Virgin," an early work; the Museum and churches of Prato, a number of panels, painted during his sojourn there; and the J. Pierpont Morgan collection (Metropolitan Museum, New York), a fine "St. Lawrence, with Sts. Cosmas and Damian and two Donors." Filippo was the head of an important school, and among his pupils were Sandro Botticelli, Benozzo Gozzoli, and his son. Consult: Supino, *Les deux Lippi* (Florence, 1904); E. C. Strutt, *Fra Filippo Lippi* (London, 1906), containing a bibliography; Henriette Mendelsohn, *Fra Filippo Lippi* (Berlin, 1909); Giorgio Vasari, *Lives of the Most Eminent Painters, Sculptors, and Architects,* translated by Gaston du C. de Vere, vol. i (London, 1912).

Filippino Lippi (1457–1504), son of Fra Filippo and Lucrezia Buti, was born at Prato. He acquired the rudiments of art from his father, whom he accompanied to Spoleto. After his father's death he was instructed by Fra Diamente, and in 1471 was apprenticed to Sandro Botticelli. One of his earliest and greatest works was the completion of the frescoes of Masaccio in the Brancacci Chapel (1480–85). He executed the task in a masterly manner, adapting his style to that of Masaccio, although retaining his own individuality. The greater part of "Sts. Peter and Paul Raising the Dead Youth," which Masaccio had begun, is by him, and he also painted the frescoes "Peter and Paul before Nero" and the "Crucifixion of St. Peter." While these works are not as direct and powerful as those of Masaccio, they are nevertheless completed with dignity and restraint.

Filippino's earliest paintings show the influence of his father. This is especially the case in the "Vision of St. Bernard," in the Badia at Florence, executed in tempera, but fine in color as an oil painting and delightful in sentiment. His other works of the early period include a delightful altarpiece in San Michele, Lucca, representing Sts. Roch, Sebastian, Jerome, and Helena; the "Virgin Enthroned" (1486), in the Uffizi, suggesting Botticelli; a fine "Madonna with Saints" and admirable portraits of the donor, Nerli, and his wife, in Santo Spirito, Florence; several madonnas and a "Crucifixion" in the Berlin Museum. To his late period, after the Roman visit, belong "Christ Appearing to the Virgin," Munich Pinakothek; "Adoration of the Kings" (1496), Uffizi; "Meeting of Joachim and Anna," Gallery of Copenhagen; "The Virgin and Child, with St. Joseph and a Child Angel" (c.1500), Altman collection, Metropolitan Museum, New York; the "Marriage of St. Catharine," an altarpiece in San Domenico, Bologna. In 1488 Filippino was commissioned to paint in the church of Santa Maria sopra Minerva, Rome, a cycle of frescoes illustrating the dogmas of the Order of St. Dominic, which he executed with great skill. He was very much impressed by the monuments of Rome, as is especially shown in his use of Renaissance decoration in later works. Fifty years before others he developed a marked baroque style, restless and exaggerated in poses, draperies, and action, and replete with grotesque decorations and broken architectural forms. Among the best of his later works are the frescoes of a tabernacle in Prato; but the most ambitious and impressive are the frescoes of the Strozzi Chapel, in Florence, completed in 1502, with subjects from the history of Sts. Philip and John. These are the most thoroughly baroque of all his achievements.

Filippino inherited from his father a talent for color superior to that of his master Botticelli; his line is softer and more undulating. But his lack of a strong personality prevented an individual development, and rendered him too amenable to foreign influence. His later works, therefore, did not fulfill the promise of his early days. No monograph on Filippino has yet appeared, but consult: A. H. Layard, *The Brancacci Chapel and Masolino, Masaccio, and Filippino Lippi,* published by the Arundel Society (London, 1868); Supino, *Les deux Lippi* (Florence, 1904); Giorgio Vasari, *Lives of the Most Eminent Painters, Sculptors, and Architects,* translated by Gaston du C. de Vere, vol. i (London, 1912).

LIP'PIA (Neo-Lat., named in honor of the French physician and traveler Augustus Lippi). A genus of shrubby and half-shrubby plants of the family Verbenaceæ, including about 90 species, mostly American, and among them the common lemon verbena (*Lippia citriodora*). This was formerly a favorite in old-fashioned flower gardens, especially in England, because of its fragrant leaves. It is a low, tender shrub, deciduous in northern climates, and should be brought into the greenhouse on the approach of frost. It grows readily from cuttings. *Lippia mexicana* has some value in bronchial affections. It contains tannin, quercetin, lippiol, etc. *Lippia nodiflora*, a low-growing species, is cultivated in Arizona and elsewhere as a substitute for grass on lawns.

LIP'PINCOTT, Joshua Ballinger (1813–86). An American publisher, founder of the house which bears his name. He was born in Burlington Co., N. J., removed to Philadelphia about 1828, and entered the book business. In 1836 he organized the firm of J. B. Lippincott & Co. and in 1850 bought the entire business of Grigg & Elliott, one of the best-known firms in Philadelphia. In 1885 the name of the concern was altered to the J. B. Lippincott Company. Upon his death he was succeeded in the presidency by his son, Craige (1846–1911), who was born in Philadelphia, studied at the University of Pennsylvania and in Europe, and entered the publishing house in 1866. In 1911, when Craige died, his younger brother, Joshua Bertram (1857–), who had been vice president since 1886, became president of the concern. He was born at Huntington Valley, Pa., studied for one year at the University of Pennsylvania, and was given an honorary B.A. in 1907.

LIPPINCOTT, Sara Jane (Clarke) (1823–1904). An American author, better known by the pseudonym Grace Greenwood. She was born at Pompey, N. Y., was educated at Rochester, and began to write at an early age. In 1853 she was married to Leander K. Lippincott. Among her works are: *Greenwood Leaves* (1850); *History of my Pets* (1850); *Poems* (1851); *Haps and Mishaps of a Tour in England* (1854); *Merrie England* (1855); *Stories from Famous Ballads* (1860); *Records of Five Years* (1867); *Stories and Sketches* (1893); *Stories for Home Folks* (1903). Consult *Recollections of My Childhood* (New York, 1903). She established *The Little Pilgrim*, a paper for children, and appeared extensively upon the platform as a lecturer and dramatic reader.

LIP'PITT, Henry Frederick (1856–). An American Republican legislator and capitalist, born at Providence, R. I. He graduated from Brown University in 1878; engaged in the cotton-manufacturing business, becoming finally general manager of the Manville Company; and was president of the New England Cotton Manufacturers' Association in 1889. He became interested also in banking, and was director of several corporations, amassing in these and other enterprises a considerable fortune. In 1911 he was elected United States Senator from Rhode Island on the Republican ticket, having advocated in his campaign a high protective tariff. He was known as a regular Republican and succeeded Senator Nelson W. Aldrich (q.v.).

LIPPMANN, lēp'mäN', Gabriel (1845–1921). A French physicist, born at Hallerich in Luxemburg. He entered the scientific department of the École Normale in Paris in 1868, and four years later went to Germany, where he studied physics and chemistry. On his return to Paris he earned the doctor's degree with remarkable theses entitled *Relation entre les phénomènes électriques et capillaires*. He enunciated the principle of the conservation of electricity, and in 1891 discovered a most ingenious method of photographing in colors by the interferential method. (See Color Photography.) He became a professor in the University of Paris in 1883 and director of the physical laboratory in the Sorbonne. In 1908 he was awarded the Nobel prize for physics. Besides a number of memoirs, he published *Cours de thermo-dynamique* (1888); *Cours d'acoustique et d'optique* (1888); *Unités eléctriques absolues* (1899); *L'Enseignement des sciences mathematiques et des sciences physiques* (1904), with others. Consult Ernest Lebon, *Gabriel Lippmann: biographie, bibliographie analytique des écrits* (Paris, 1911), and other works.

LIPP'MANN, Walter (1889–). An American writer on political and social subjects, born in New York City. Graduating from Harvard in 1910, he was for a short time a staff writer on the *Boston Common* and on *Everybody's Magazine* (1910–11); became a contributor to the *American Magazine*, to the *Forum*, to the *Times Book Review*, and to various Socialist publications; and in 1914 joined the board of editors of the *New Republic*. In 1911 he was executive secretary to Mayor Lunn of Schenectady, N. Y. He is author of *Introduction to the Poems of Paul Mariett* (1913); *A Preface to Politics* (1913); *Drift and Mastery* (1914).

LIPPS, lĭps, Theodor (1851–1914). A German psychologist. He was born at Wallhalben, Bavaria; studied at Erlangen, Tübingen, Utrecht, and Bonn; and was professor at Breslau from 1884 to 1894 and after that until 1913 at Munich. He became best known for his contributions to the psychology of space perception and to psychological æsthetics. He published *Grundtatsachen des Seelenlebens* (1883, 1912); *Psychologische Studien* (1885, 1905); *Der Streit über die Tragödie* (1890); *Æsthetische Factoren der Raumanschauung* (1891); *Grundzüge der Logik* (1893, 1912); *Zur Psychologie der Suggestion* (1897); *Raumästhetik und geometrisch-optische Täuschungen* (1897); *Komik und Humor: Eine psychologisch-ästhetische Untersuchung* (1898); *Ethische Grundfragen* (1889; 3d ed., 1912); *Selbstbewusstsein, Empfindung und Gefühl* (1901); *Vom Fühlen, Wollen, und Denken* (1902, 1912); *Leitfaden der Psychologie* (1903; 3d ed., 1909); *Æsthetik* (1903–06); *Naturwissenschaft und Weltanschauung* (1906); *Philosophie und Wirklichkeit* (1907); *Naturphilosophie* (1907). He edited *Psychologische Untersuchungen* after 1905, and, with R. M. Werner, *Beiträge zur Aesthetik* after 1890.

LIPPSTADT, lĭp'stät. A town of Westphalia, Prussia, on the Lippe, 13 miles northeast of Soest (Map: Germany, C 3). It has a considerable grain trade and manufactures iron, soap, thread, felt, vehicles, metal goods, brushes, bricks, tobacco, rope, and brandy. It bakes much of the famous Westphalian rye bread known as pumpernickel. Pop., 1900, 12,534; 1910, 16,360. The town was founded in the twelfth century by the Lord of Lippe. From the seventeenth century it was the joint property of Brandenburg and Lippe. In 1850 Lippe ceded its rights to Prussia.

LIP READING. The art of reading speech by watching the lip movements of the speaker. Lip reading is used by deaf or hard-of-hearing persons, either instinctively or as a result of definite training. It may merely supplement the auditory faculties in those whose hearing is not greatly impaired. Such persons should cultivate the art if tests indicate that the hearing will grow worse. If, on the other hand, there is a prospect that a useful degree of audition will be restored by treatment, efforts should be made in this direction, rather than abandon the ears and depend on lip reading. Authorities are divided as to whether or not lip reading has a deleterious effect on audition by encouraging dependence on the eye rather than the ear. The advocates of the method declare there is no such effect, but that hearing is sometimes benefited. Certain individuals find the strain of watching the lips and trying to hear at the same time very confusing. Others who are so deaf that they fall into a condition of neurasthenia from the constant effort of trying to hear, are much benefited in every way when they learn the art of lip reading. It is evident, therefore, that selection must be exercised in advising the deaf to learn to read the lips, but the method presents many advantages over the use of artificial aids such as ear trumpets, pocket telephones, etc.

The teaching of the art has been brought to a high degree of perfection by Nitchie and others. A certain amount of intelligence and visual alertness on the part of the pupil is essential. The eye must follow both the lips and facial movements, and the mind must be quick to supply what the lips are not able to convey.

Lip reading may be taught either by a teacher or may be mastered by means of practice before a mirror. A skilled instructor should be obtained whenever possible, the mirror being used for practice. The pupil's focus of vision should be the upper teeth, this being the centre from which all lip movements or facial expressions can most readily be seen. The instructor at first repeats short sentences or stories over and over until the pupil can read them from the lips. This is followed by more difficult exercises, based on analysis of the various lip movements. For example, the "lip-shut movement" is used when studying the letters *p*, *b* and *m:* the pupil watches the lips of the instructor, who repeats words containing these letters until he can distinguish them. In using the mirror the pupil commits to memory short anecdotes or stories and exercises, observing narrowly the movements of his own lips as he repeats them before a looking glass.

Many deaf persons become so expert in this art that their infirmity passes unnoticed. General conversation is more difficult for the lip reader than talk between two persons, but even this can be mastered to some degree. Consult: E. B. Nitchie, *Lessons in Lip-Reading* (New York, 1909); id., *Lip-Reading Principles and Practice* (ib., 1912); J. Müller-Wade, *Exercises in Lip Reading for the Adult Deaf* (Springfield, Mass., 1912).

LIPS, Diseases of the. The lips, in common with other portions of the body, may be the seat of tumors, cysts, and deformities. A vesicular eruption, *herpes labialis*, occurs during fevers, acute colds, and gastric disturbances. Cracks and fissures may result from exposure to the sun and wind or in chronic form may be a symptom of congenital syphilis. Superficial ulcers are seen on the mucous surface of the lips in secondary syphilis. Hypertrophy of the upper lip is often observed in strumous children and in persons suffering from chronic nasal catarrh. The fact that the lips are covered with skin on one aspect and mucous membrane on the other, with a mucocutaneous junction, makes their affections at times peculiar. These will be sufficiently described under such articles as Harelip; Nævus; Papilloma; Syphilis; Tumor.

LIPS, lêps, Johann Heinrich (1758–1817). A Swiss line engraver. He was born at Kloten, near Zurich, where he was the pupil of Lavater. Afterward he studied at the academies of Mannheim and Düsseldorf. He twice visited Rome and in 1789 was appointed professor at Weimar through the influence of Goethe, who greatly admired his works. He is noted for his plates after the old masters, whose works he interpreted with skill and finish. He left about 1400 pieces, such as the "Martyrdom of St. Sebastian," after Van Dyck; "The Adoration of the Magi," after Annibale Carracci; "The Bacchanal," after N. Poussin; and the portraits of Goethe, Wieland, and other celebrated contemporaries. He was also a painter in water color.—His son and pupil, Johann Jakob (1790–1833), an engraver, made portraits of Ludwig of Bavaria, Hebel, and others.

LIPSCHITZ, lĭp′shĭts, Rudolf (1832–1903). A German mathematician, born in Königsberg, Prussia. In 1857 he became a privatdocent in Bonn and in 1862 professor at Breslau. Two years later he returned to Bonn as professor, where he remained until his death. He was an extensive contributor to mathematical literature, especially in the higher analysis, including the calculus of variations, the theory of Bernoulli numbers, Bessel's functions, Fourier's series, and the theory of prime numbers. These contributions appeared chiefly in Crelle's *Journal* and in the *Comptes Rendus*. He wrote *Lehrbuch der Analysis* (2 vols., Bonn, 1877, 1880); *Wissenschaft und Staat* (ib., 1874); *Untersuchungen über die Summen von Quadraten* (ib., 1886); *Bedeutung der theoretischen Mechanik* (Berlin, 1876).

LIPSCOMB, lĭps′kŭm, Andrew Adgate (1816–90). An American clergyman and educator, born at Georgetown, D. C. He entered the ministry of the Methodist Protestant church, joining the Maryland conference in 1835, and for some time was president of the Alabama conference. Compelled by ill health to retire from the ministry, he founded in 1849 the Metropolitan Institute for Young Ladies at Montgomery, Ala. From 1856 to 1859 he was president of the Tuskegee Female College of the Methodist Episcopal Church South and from 1860 to 1874 chancellor of the University of Georgia. In 1875 he was elected professor of philosophy and criticism in Vanderbilt University. He became professor emeritus several years before his death. He was the author of *Studies in the Forty Days between Christ's Resurrection and Ascension* (1885) and *Studies Supplementary to the Studies in the Forty Days between Christ's Resurrection and Ascension* (1886).

LIPSIUS, lĭp′sĭ-ụs, Ida Marie (1837–). A German writer on music, known by her pseudonym, La Mara. A sister of the classical philologist Justus Hermann Lipsius, she was born in Leipzig and wrote several sketches of travel, *Im Hochgbirge* (1876), *Sommerglück* (1881), and *Im Lande der Sehnsucht* (1901). Her musical publications include the essays *Musikalische Studienköpfe* (5 vols., 1868–82; 11th ed., 1913) and *Klassisches und Romantisches aus der Tonwelt* (1892); the collection of *Gedanken berühmter Musiker über ihre Kunst* (1876), and of *Musikerbriefe aus fünf Jahrhunderten* (1886); editions of Liszt's letters (8 vols., 2d ed., 1893–1905), of his correspondence with Von Bülow (1898) and Charles Alexander, Grand Duke of Saxony (1908), and of Berlioz's letters to Princess Sayn-Wittgenstein (1903); and a translation into German of Liszt's *Chopin* (3d ed., 1910). She published also *Beethovens unsterbliche Geliebte: Das Geheimnis der Gräfin Brunswik und ihre Memoiren* (1909); *Liszt und die Frauen* (1911).

LIPSIUS, Justus (1547–1606). The Latinized form of Joest Lips, a celebrated philologian and humanist, born at Oberryssche in Brabant. He studied law and humanism at the Jesuit College in Cologne and at Louvain. In 1567 he published his essays, *Variarum Lectionum Libri Tres*, which secured him the favor of Cardinal Granvella, who took him to Rome and made him his secretary. From 1569 to 1572 he led the life of a wandering scholar in the Low Countries, Germany, and Austria, turning Lutheran in the latter year to take the chair of history at Jena, where he remained for two years. After living for some time at Cologne, Louvain, and Antwerp, he became in 1579 professor of history at Leyden, embracing at the same time the Calvinistic faith. In 1590 he became reconciled with the Church and received the chair of Latin at Louvain (1592). There he remained till his death. Probably the greatest authority of his age on Roman antiquities, Lipsius contributed greatly to the development of the study of the language and history of ancient Rome by a large number of editions of the Latin historians and philosophers, preëminent among which is the monumental edition of Tacitus, which has remained a standard to the present day (1st ed., Antwerp, 1574; 6th ed., corrected by the author, 1605). He also published editions of Velleius Paterculus, Valerius Maximus, and Seneca, besides numerous original contributions dealing with the material and intellectual life of the ancient Romans. Among these are: *De Amphitheatro* (1584); *De Cruce* (1593); *De Militia Romana* (1595); *De Vesta et Vestalibus Syntagma* (1603). His philosophical views, which were those of the Stoics, were embodied in the *De Constantia* (1584) and the *Manuductio ad Stoicam Philosophiam* (1604). His correspondence has been published in part. His *Opera Omnia* appeared at Antwerp in 1637. Consult Galesloot, *Particularités sur la vie de Justus Lipsius* (Bruges, 1877), and Amiel, *Un publiciste du 16ème siècle: Juste Lipse* (Paris, 1884).

LIPSIUS, Justus Hermann (1834–). A German classical scholar, born at Leipzig, professor in the university of his native city after 1869. He was editor of Andocides (1888) and of Demosthenes, *On the Crown* (1884), reviser of Meier and Schömann's *Der attische Prozess* (2 vols., Berlin, 1883, 1887) and of Schömann's *Griechische Altertümer* (2 vols., ib., 1897, 1901), and author of *Attisches Recht und Rechtsverfassung* (1905–12). He wrote numerous philological papers and edited *Leipziger Studien zur klassischen Philologie*.

LIPSIUS, Richard Adelbert (1830–92). A German theologian, brother of the preceding, born at Gera. He studied at Leipzig, was appointed professor of theology there, and afterward at the universities of Vienna, Kiel, and Jena (1871). In 1874 he was nominated a member of the Weimar Synod. Lipsius belongs to the moderate representatives of liberal theology; in historical research he recognizes the propriety of scientific criticism, and on matters of dogma sides with Kant, who requires harmony between revelation and the actual existence of the world. His *Lehrbuch der evangelischprotestantischen Dogmatik* (3d ed., 1893) is noteworthy. His other contributions to theological literature, among many, include: "Der Gnosticismus," in Ersch and Gruber's *Encyclopädie* (1860); *Die Quellen der ältesten Ketzergeschichte* (1875); *Philosophie und Religion* (1885); *Unser gemeinsamer Glaubensgrund im Kampfe gegen Rom* (1890).

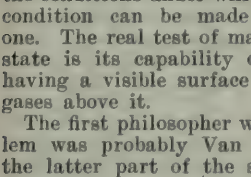
LIP'SOS (anc. *Lepsia*). A small island in the Ægean Sea, off the coast of Asia Minor, one of the Dodecanesia (q.v.) group, 6 miles southeast of Patmos.

LIP'TON, Sir Thomas Johnstone (1850– .) A British merchant and yachtsman, born in Glasgow, Scotland, of Irish parentage. Coming to the United States when 15 years old, he worked in New York City as a clerk for a short time, and then for two years in the South —in New Orleans as a street-car driver and in South Carolina as a laborer on rice plantations. He returned to Glasgow and in 1876 opened there a grocery store. From this small beginning his business expanded and came to include many stores in Great Britain, as well as tea, coffee, and cocoa plantations in India, rubber estates in Ceylon, and a large pork-packing establishment in Chicago. He gave liberally to many charitable undertakings, e.g., $100,000 in 1897 to the Alexandra Trust Fund for providing cheap dinners for working people. From boyhood he was an enthusiastic sailor, and in his later years he became famous for his attempts to win back the *America's* Cup. (See Yacht and Yachting.) Lipton was knighted in 1898 and was made Baronet in 1902. In 1915 he used his steam yacht to carry nurses and supplies to Servia for sufferers from the European War.

LIQUA'TION, or **ELIQUATION.** In metallurgy the process of separating metals differing in fusibility, by applying heat sufficient to melt one and leave the other in the solid state. It is a process of antiquity, having been used up to 1836 at Mansfeld, Prussia, in the treatment of argentiferous copper and lead ores. Lead containing antimony and some other metals may be partially freed from them and prepared for other treatment by a process of liquation. Antimony may be removed from its ores by applying a heat which will cause the molten metal to flow from the ore, leaving the latter intact by reason of its much higher melting point. Copper and lead alloys may also be separated in the same way. See Silver.

LIQ'UEFAC'TION OF GASES (Lat. *liquefactio*, from *liquefacere*, to make liquid, from *liquidus*, liquid, from *liquere*, to be fluid + *facere*, to make). Matter exists in different forms as solids, liquids, and gases, which may be roughly discriminated: A solid is matter in such a form that it keeps both its size and shape under all ordinary conditions; a liquid has, as a rule, a definite volume, but will assume the shape of any vessel in which it is placed; while, if allowed to fall freely so as to form drops, these are spherical; a gas, on the other hand, will take both the shape and volume of the solid vessel which contains it. Water in these three forms is ice, ordinary water, and steam. Every one is familiar with the fact that it is easy to make any one of these forms of water pass into any other. Thus, in nature, we have the formation of ice, hail, and snow, all of which in turn melt and form water or else vaporize and form steam. Similarly we have the water evaporating from the surfaces of lakes and oceans, and the reverse process, the formation of rain and dew. These changes of matter from one form into another are called "changes of state," and the subject "liquefaction of gases" deals with the conditions under which matter in the gaseous condition can be made to assume the liquid one. The real test of matter being in the liquid state is its capability of forming drops or of having a visible surface of separation from the gases above it.

The first philosopher who considered this problem was probably Van Helmont, who lived in the latter part of the sixteenth and the early part of the seventeenth century. He introduced into science the word "gas" and distinguished between what he called "gases" and "vapors," saying that the latter could be condensed into the liquid state, while the former could not. This distinction has persisted in science up to within recent years. As early as the first year of the nineteenth century Dalton, the great English chemist, made the statement: "There can scarcely be a doubt entertained respecting the reducibility of all elastic fluids of whatever kind into liquids; and we ought not to despair of effecting it in low temperatures, and by strong pressures exerted on the unmixed gases." But up to the time of Faraday comparatively little experimental work has been done.



APPARATUS OF FARADAY FOR THE LIQUEFACTION OF CHLORINE, SULPHUROUS ACID GAS, ETC.

The substances which by their reaction produce the gas are placed in one end of a bent glass tube, and the open end is then sealed. If these reacting substances are in the end *a*, this is heated, thus causing the active evolution of the gas, while the other end, *b*, is cooled as far as necessary or possible. Thus, the gas in the end *b* is under high pressure and at a low temperature.

In 1823, at the suggestion of Sir Humphry Davy, Faraday began a series of experiments which ended in his securing a general method for the liquefaction of gases which he applied to chlorine, sulphurous acid, carbonic acid, cyanogen, and many others. This method was to generate the gases in large amounts in a small space so that the pressure was great and then to cool the gases, while under this high pressure, to a sufficiently low degree. In 1845 Faraday published a second series of researches describing his observations on gases which he had succeeded in liquefying, by making use of temperatures much lower than those which he had been able to obtain in his first investigation. He thus succeeded in liquefying all gases then known, with the exception of hydrogen, oxygen, nitrogen, nitric oxide, and marsh gas. He subjected oxygen to a pressure of about 1000 pounds to the square inch, but it showed no signs of liquefaction. In speaking, however, of his efforts to liquefy these so-called "permanent gases," he states: "Further diminution of temperature and improved apparatus for pressure may very well be expected to give us these bodies in the liquid or solid state."

This hope of Faraday's was rendered much more certain by the work of Andrews on the properties of carbon dioxide under varying temperatures and pressures which began in 1863 and was published finally in 1869. The chief result of Andrews's work was the proof that for carbon dioxide, and probably therefore for other gases, there was a certain temperature, different for different substances, below which the gas must be cooled before any amount of pressure, however great, would cause it to liquefy. This temperature is called the "critical temperature." It was evident, then, that the explanation of all previous work on the liquefaction of gases which had been successful was the fact that the experimenters had used gases whose critical temperatures were not lower than the lowest temperatures available in laboratories; while the lack of success in the attempts to liquefy the permanent gases was owing to the fact that the critical temperatures of these gases were extremely low. The problem, then, to liquefy the permanent gases took the form of an investigation as to the means of securing extremely low temperatures.

Methods for the production of low temperatures may be conveniently divided into four classes.

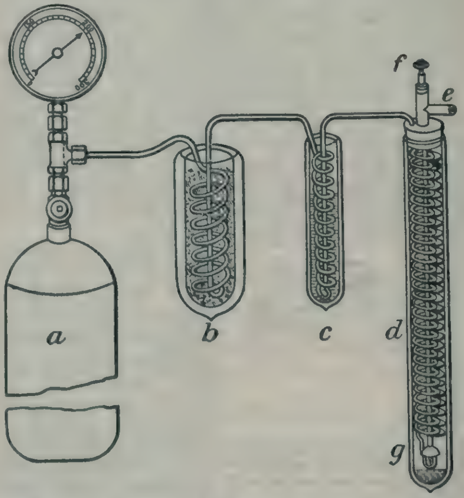
The Use of Freezing Mixtures. It has been known for many years that a mixture of common table salt and ice produced a temperature many degrees below that of melting ice when pure, viz., 0° C. The lowest temperature available by using this salt and ice, when mixed in suitable proportion, is −22° C. It was found, however, by Thilorier that by mixing solid carbon dioxide, which he was able to secure by a method to be described presently, and ordinary sulphuric ether the mixture had a temperature of −110° C. This mixture, always known as "Thilorier's mixture," was first studied by him in 1834 and formed for many years the only means of securing extremely low temperatures. In fact, there is at the present time no freezing mixture in use that gives a temperature lower than this.

The Method of Evaporation. It was recognized by all the investigators in the subject of heat, notably by Leslie and Black, that when a liquid evaporated rapidly the surrounding objects, and especially the solid vessels which contained the liquid, gave up a great deal of heat, and that thus their temperature fell. This is owing to the fact that it requires heat to produce evaporation; and so, if evaporation ever takes place, a definite amount of heat must be taken away from the neighboring matter. In this manner Leslie and Wollaston showed that water could be frozen by means of its own evaporation. The first use, however, of this fact concerning the low temperatures produced by evaporation made to secure liquefaction of gases was in the investigation of Bussy in 1824, who observed that if liquid sulphurous acid was made to evaporate rapidly he could get a temperature as low as −65° C., and, using this method, he liquefied chlorine, ammonia, and cyanogen, and in fact solidified the last-named gas. This method of securing low temperature immediately came into general use and is still used in many processes.

Method of Expansion. It was noted by investigators early in the nineteenth century, if not before, that when a gas under high pressure is allowed to expand into the open air or to escape through a small opening, it experiences a drop in temperature; and the laws concerning this fall were studied by Gay-Lussac and many others. The first practical use, however, of the method with reference to liquefying gases was made in 1834, while Thilorier liquefied and even solidified carbonic-acid gas by allowing it to expand suddenly. He made use further of the low temperatures thus obtained by expansion in studying many physical properties of bodies. This method was extended also by Mitchell in 1839 and was used practically by Dr. John Gorrie, who in 1849 constructed an ice machine based on the low temperature produced by the expansion of compressed air. This method of first compressing a gas, causing it to be cooled to a temperature as extreme as possible by ordinary means, and then allowing it to expand suddenly is the standard method now in use in all machines made for liquefying gases. There are two processes involved in this production of low temperature by expansion. It is evident that, if a gas compressed in a cylinder is allowed to escape through a small opening, work will be done both in overcoming the pressure of the air and also in giving kinetic energy to the rapidly escaping gas. This work must be done by the gas itself which stays behind and, as it were, pushes out the other gas; and therefore its temperature falls. There is a second reason, however, depending upon the fact first discovered in the experiments by Joule and Thomson (later Lord Kelvin). This is that there is a change in the intrinsic energy of a gas when it occupies a small volume and its molecules are thus close together, and when it fills a larger volume and its molecules are far apart. It is observed that if oxygen or nitrogen or any of the ordinary gases, with the exception of hydrogen, is allowed to expand, doing no external work, the temperature of the gas falls. In the case of hydrogen it was found that at ordinary temperatures if "free" expansion takes place, there being no external work done, the temperature rises. However, if the initial temperature of the hydrogen is sufficiently low, then the expansion will produce a further *fall* in temperature. Thus, when any gas is under pressure at a low temperature and is allowed to expand by escaping into a space at a lower pressure, this temperature will fall; and if it is under sufficiently high pressure, the gas may thus be liquefied.

The Regenerative Method. In this method gas under pressure is allowed to expand, and then, having thus been cooled, it is driven back and made to circulate round the outside of the vessel which contains the compressed gas. In this manner the temperature of the compressed gas is being brought down continually lower and lower, until, finally, it is at a temperature so low that any further decrease in temperature will produce liquefaction. This method was first used by Siemens in 1857. The first suggestion that this principle should be used in the scientific study of the liquefaction of air and other gases was due to Edwin J. Houston in 1874. Since this time the regenerative principle has been used by several investigators, notably by Prof. Kamerlingh Onnes in 1894 and by Professor Dewar in 1895. In all the commercial forms of machines this principle forms one of the essential features of the apparatus.

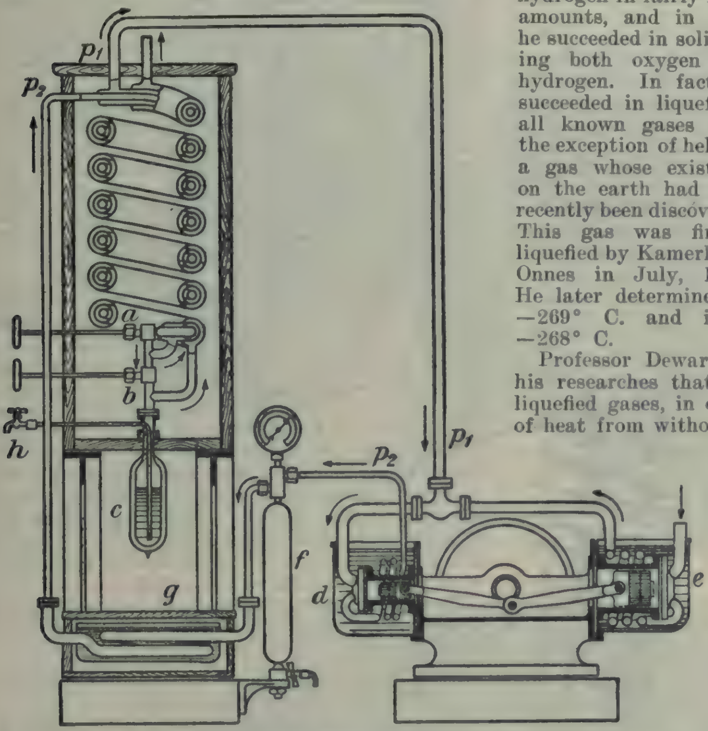
After the publication of Andrews's researches in 1869, work proceeded very rapidly, and finally, in December, 1877, oxygen was liquefied by two investigators working independently—Cailletet, one of the greatest ironmasters of France, experimenting at his works at Châtillon-sur-Seine, and Pictet, a maker of machines for manufacturing ice, working at Geneva. The latter liquefied oxygen at a pressure of 320 atmospheres and a temperature of —140° C., producing his low temperature by a combination of the methods of evaporation and expansion; and the former compressed his oxygen and carbon monoxide to a pressure of 200 atmospheres, cooled it to a temperature of about —28° C., and then allowed it to expand suddenly. Cailletet succeeded in his experiments on December 2, and Pictet succeeded in his December 22; an announcement was made to the world of the results of both at the meeting of the French Academy on Dec. 24, 1877. Neither of these observers obtained oxygen in any large amounts or in a static condition, practically only a mist being formed. Cailletet proceeded to liquefy both nitrogen and air; but both he and Pictet secured only the faintest evidence of the liquefaction of hydrogen. The first to obtain oxygen, nitrogen, and carbon monoxide in fairly large amounts were Wroblewski and Olszewski, who began their work at Cracow in 1883. The method used by them was simply to produce a low temperature by a combination of freezing mixtures and the evaporation of liquids, and under these conditions if the pressure of the gas is sufficiently great it is liquefied. Experiments were made on hydrogen, but their greatest success was simply to obtain a slight froth and other signs of ebullition; they failed to secure any drops of the liquid. These observers were



APPARATUS OF DEWAR FOR THE LIQUEFACTION OF HYDROGEN.

a represents one of the cylinders containing hydrogen under the pressure of about 200 atmospheres; *b* is a Dewar flask containing liquid carbonic acid evaporating under exhaustion; *c* is a similar flask containing liquid air; *d* is the regenerative coil through which the gas under pressure is passed, and over which, after being cooled by expansion, it is drawn; *g* is the pin-hole nozzle through which the compressed gas expands, escaping at the rate of about 15 cubic feet per second; *e* is an opening through which the gas can be withdrawn and again compressed; *f* is the valve by which the size of the pin-hole nozzle *g* is regulated. The flask containing the regenerative coil is a doubly silvered vacuum vessel, and is surrounded with a space kept below — 200° C. The liquid hydrogen, when formed, drops from this vacuum vessel into another which is doubly insulated by being surrounded with a third vacuum vessel.

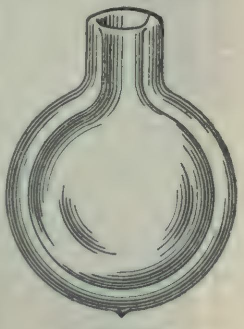
the first to make a careful study of the physical properties of gases at low temperatures, measuring their critical temperatures and pressures, their boiling points, isothermals, etc. Olszewski succeeded in solidifying a number of gases, especially carbon monoxide and nitrogen, and measuring their freezing points. He was the first to make use of the evaporation of liquid oxygen and liquid air as a means of producing low temperatures.



LINDE APPARATUS FOR THE LIQUEFACTION OF AIR.

The most important parts of the Linde machine, as described in the specifications of the makers, are the two-cylinder air compressor and the countercurrent interchanger. The former is driven by means of a belt, from an electric or other motor. The interchanger consists of a triple spiral of three copper tubes wound one inside the other. The compressed air at the temperature of the coil *g* and at about 200 atmospheres' pressure passes through the inmost tube of the spiral from top to bottom, and passes out at the lower end through a valve *a* under a pressure of some 16 atmospheres. It returns upward through the annular space between the inner and middle pipes and is then again raised to a pressure of 200 atmospheres by the smaller cylinder *d* of the compressor and then begins the same cycle over again. The large cylinder *e* of the compressor pumps a small amount of air from the atmosphere into the suction pipe of the small cylinder, that is to say, at 16 atmospheres. A similar quantity of air must therefore leave the cycle at another point so that the pressure may remain constant. This escape of gas takes place at the lower end of the countercurrent interchanger immediately after the discharge from 200 to 16 atmospheres, so that a controllable amount of air issues from 16 atmospheres to 1 atmosphere through a second valve *b* and escapes through the outer annular space of the triple copper tube. Part of this air, when the apparatus is cooled down to the temperature of liquefaction, then becomes liquefied and collects in a Dewar flask, *c*, which is fixed to the lower end of the countercurrent interchanger. By means of a little pipe reaching to the bottom of the glass vessel the liquid may be run off through the cock *h*. That part of the air issuing from the second valve which is not liquefied leaves the apparatus, escaping through the space between the middle and outside pipes of the spiral into the atmosphere. A small quantity of water is continually injected into the suction pipe of the low-pressure cylinder in order to fill the clearance and to lower the final temperature of compression. This water, together with the moisture contained in the air, must be as far as possible completely separated out, so as to avoid stopping up the inside coil with ice. This is done first of all by means of a water separator, *f*, which holds back water carried over with the air in mechanical suspension, and secondly by means of an iron pipe in the form of a coil, *g*, which is cooled down to a few degrees below zero by a freezing mixture of ice and chloride of calcium, and freezes out the small quantities of water vapor contained in the highly compressed air until only traces remain.

The greatest advances made in recent years in the field of low-temperature research are undoubtedly those due to the investigations of Professor Sir James Dewar at the Royal Institution, London, and of Professor Kamerlingh Onnes at the University of Leyden. They have succeeded in obtaining liquid oxygen, nitrogen, and air in practically unlimited amounts. Dewar was able to solidify air as early as 1893; on May 10, 1898, he obtained liquid hydrogen in fairly large amounts, and in 1899 he succeeded in solidifying both oxygen and hydrogen. In fact, he succeeded in liquefying all known gases with the exception of helium, a gas whose existence on the earth had only recently been discovered. This gas was finally liquefied by Kamerlingh Onnes in July, 1908. He later determined its boiling point as being −269° C. and its critical temperature as −268° C.



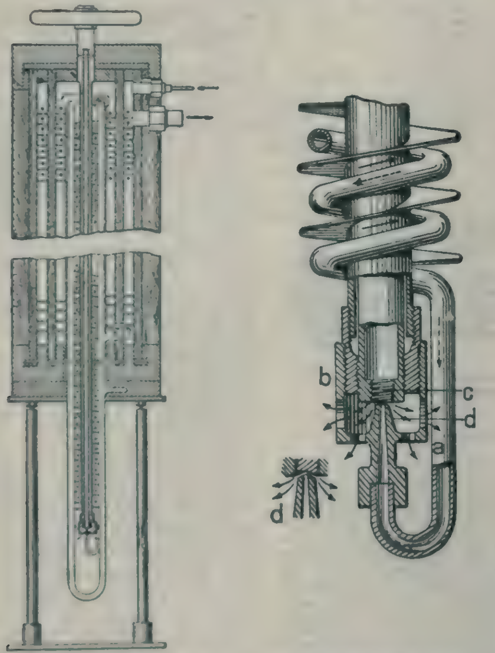
DEWAR BULB.

Professor Dewar discovered in the course of his researches that the best vessel for holding liquefied gases, in order to guard against access of heat from without, was a double-walled glass bulb, the space between the walls being completely exhausted of air, and the glass being silvered like a mirror so as to reflect radiation. This vessel is called the "Dewar bulb." (This is the principle of the ordinary "thermos bottle.") Important simplifications in the apparatus of Dewar for the liquefaction of hydrogen have been made by Travers and others.

As soon as it was found possible to liquefy gases with comparative ease, several machines were made in order to obtain liquefied air for commercial purposes. The most important of these are those invented by Linde in Germany, Hampson in England, and Tripler in America. These machines were all invented at about the same time (early in 1895), and all made use of the same principle, viz., the regenerative method. With these machines liquid air can be obtained in almost unlimited quantities and in a comparatively short time.

Innumerable uses have been found for liquefied gases, both in scientific investigations and in industrial applications. The low temperatures which can thus be obtained are useful in many chemical experiments, and also in many spectroscopic investigations where it is essential to secure pure gases. Liquid carbonic acid is used in the preparation of all kinds of aërated waters, viz., soda water, and also in the manufacture of salicylic acid. Enormous quantities of liquid sulphurous acid, which is used for many purposes, are now prepared for the market. Liquid nitrous oxide is used as an anæsthetic for minor surgical operations, especially in dentistry. Liquefied gases are used in the operation of most ice-machine plants. Liquid oxygen can be obtained commercially and is used extensively in hospitals. It has been thought that liquid air would be used as a motive power, but so far all attempts to control it have failed.

At temperatures as low as those of liquid air and solid hydrogen all the ordinary properties of matter would be expected to change, and a careful study of these changes has been made by many investigators, notably by Professor Dewar. A few facts may be noted here. The electrical resistance of metals decreases as the temperature is lowered, and in many cases the relative order of metals with reference to their electrical resistance is changed at low temperatures. Thus, at ordinary temperatures silver is a better conductor than copper, whereas at −200° the reverse is true. (See RESISTANCE.) The thermoelectric properties of bodies change to a marked degree. The magnetic moment of magnets is increased by 30 or 40 per cent as the temperature is lowered to −200°. The elastic constants of bodies increase by as much as four or five times when the temperature is lowered from +15° to −182°. Rubber becomes brittle. Changes of color often take place, the original hue, however, returning in all cases when the temperature is restored. There are many curious phosphorescent phenomena at low temperature. Milk becomes highly phosphorescent. An egg shines as a globe of blue light. Chemical affinity is almost completely destroyed by cold; phosphorus, sodium, and potassium when placed in liquid oxygen remain absolutely unaffected. Photographic films retain only about one-fifth of their ordinary sensitiveness to light. The power of charcoal to absorb gases is greatly increased at low temperatures, and this fact is made use of in securing high vacua in closed bulbs.



APPARATUS OF HAMPSON FOR THE LIQUEFACTION OF AIR.

The gas to be liquefied is introduced through the small tube at the top under a pressure of about 120 atmospheres entering at ordinary room temperature. This tube is extended downward in a spiral wound round the central column; and at its lower end there is an expansion valve which is regulated from above by means of a screw. (The details are shown in the second cut.) The gas, cooled by expansion, passes up through the apparatus and out again by the large pipe shown at the upper end. The coil *a*, carrying the compressed gas, ends in the jet *d*, which can be opened or closed by the screw *c*, regulated from above. The path of the gas after expansion is shown by the arrows. The regenerative principle is evident.

One of the most important commercial applications of low temperatures is the preparation of oxygen and nitrogen on a large scale. Air is liquefied, and then by a process of fractional distillation the two gases are separated. The nitrogen thus produced is used in the manufacture of ammonia, cyanamide, etc.; and the oxygen has many commercial applications.

Some interesting experiments have been tried dealing with vital phenomena at low temperatures. Warm-blooded animals, of course, perish at comparatively high temperatures, but it was found that bacteria can bear with impunity almost any temperature, however low. Sterilization does not result even after an exposure for one hour to a temperature of −182°; the germinating power of seeds is also unimpaired; blood, meat, and milk when sealed in glass tubes undergo putrefaction in the ordinary course. In other words, life can exist at 21° from the absolute zero, and probably much nearer, under conditions which nevertheless almost completely stop chemical and molecular action.

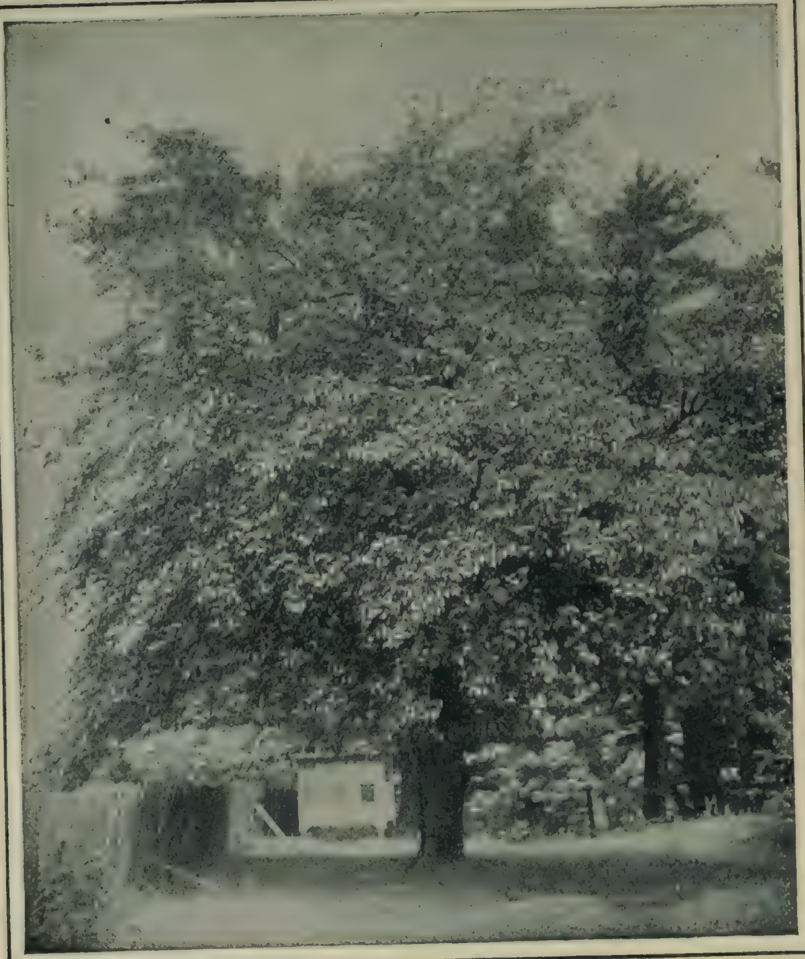
It may be interesting to note in tabular form a few of the physical constants of the gases and their liquids:

SUBSTANCE	Critical temperature	Boiling point at atmospheric pressure	Freezing point	Color of liquid
Alcohol	+243.6° C.	+78.3° C.	−130° C.	Colorless
Ammonia	+130	−33.7	−75	"
Argon	−121	−187	−189.6	"
Carbon dioxide	+31.3	−78.2	−65	"
Carbon monoxide	−139.5	−190	−211	"
Fluorine	−120 (?)	−187	−233	Yellow
Hydrogen	−243	−253	−247	Colorless
Nitrogen	−146	−195.5	−215	"
Oxygen	−118.3	−185	−235	Pale blue
Water	+358.1	+100	Zero	Colorless

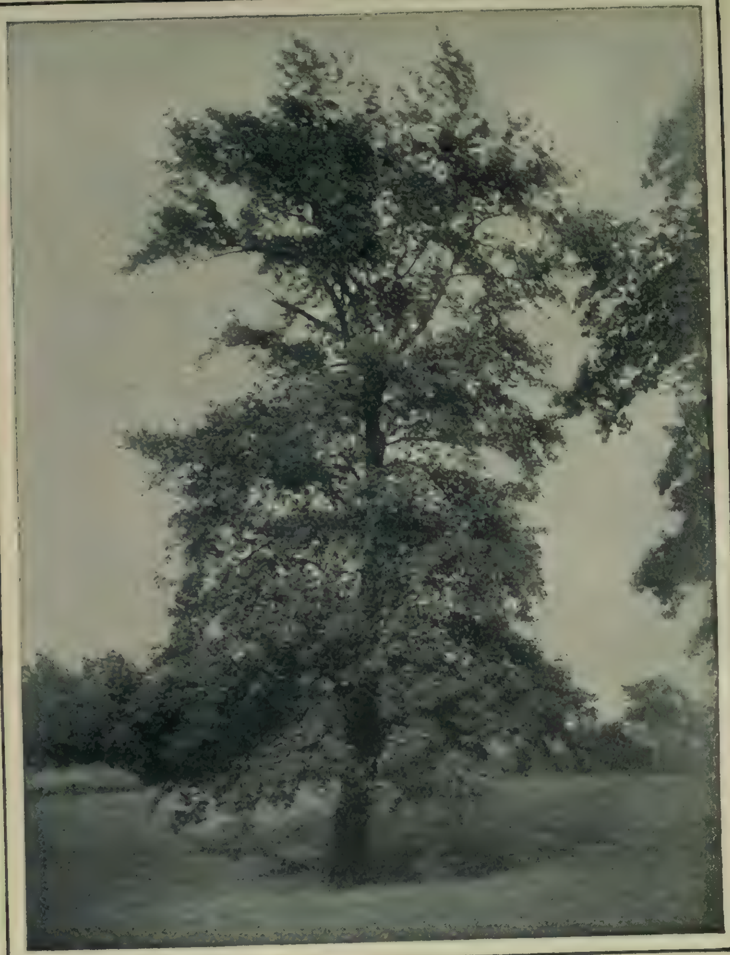
In connection with these figures it should be stated that there are several lines of argument, based upon physical experiments, which lead scientists to believe that it is impossible for us to obtain by any physical means a temperature lower than about −273° C. This temperature is called "absolutely zero," and the nearest approach made to it by any experiments so far performed has been in the work of Onnes, who has claimed to have reached a temperature less than 2° above absolute zero.

Bibliography. A complete history of the subject of liquefaction of gases will be found in W. L. Hardin, *The Rise and Development of the Liquefaction of Gases* (New York, 1899). There is also an interesting article by A. M. Clerke on "Low Temperature Research at the Royal Institution, 1893–1900," in the *Proceedings of the Royal Institution of Great Britain*, vol. xvi (London, 1901); T. O. Sloane, *Liquid Air* (2d ed., New

MULBERRY AND LIQUIDAMBAR



MULBERRY (Morus alba).



LIQUIDAMBAR (Liquidambar styraciflua).

York, 1899); W. C. D. Whetham, *Recent Development of Physical Science* (Philadelphia, 1904); G. Claude, *Liquid Air, Oxygen, Nitrogen* (ib., 1913). For Dewar's work, consult *Proceedings of the Royal Institute* from 1878 to the present time (London); and for Onnes's, see *Communications from the Physical Laboratory at the University of Leyden* (Leyden).

LIQUEUR, lê-kẽr′ (Fr., liquor). The name given to any alcoholic preparation which is flavored or perfumed and sweetened to be more agreeable to the taste. Many of the most famous liqueurs were first made by monks as cordials for the sick, and the secret of their composition has been transmitted from one generation to another in convents and monasteries. *Aniseed cordial* is prepared by flavoring weak spirit with aniseed, coriander, and sweet fennel seed, and sweetening with clarified sirup of refined sugar. *Clove cordial*, much sold in the London ginshops, is flavored with cloves, bruised and colored with burned sugar. *Peppermint*, a common liqueur, especially among the lower classes of London, consists of the ordinary sweetened gin, flavored with essential oil of peppermint, which is previously rubbed up with refined sugar.

Among the other commercial liqueurs, the following are the chief varieties: absinthe, anisette, Benedictine, cassis, chartreuse, crème de menthe, crème de rose, crème de vanilla, etc., curaçoa, kirschwasser, kümmel, maraschino, noyau, pomeranzen, ratafia, trappistine, usquebaugh, vermouth. Most of these are elsewhere described under their respective names. The composition of some of the well-known liqueurs, as given by König, is shown in the accompanying table:

COMPOSITION OF VARIOUS LIQUEURS

LIQUEURS	Specific gravity	Alcohol by volume	Alcohol by weight	Extract	Cane sugar	Other extractives	Ash
Absinthe	0.9116	58.93	....	0.18	....	0.32	....
Benedictine	1.0709	52.00	44.4	36.00	32.57	3.43	.043
Ginger	1.0481	47.5	40.2	27.79	25.92	1.87	.141
Crème de menthe	1.0447	48.0	40.7	28.28	27.63	0.65	.068
Anisette of Bordeaux	1.0847	42.0	35.2	34.82	34.44	0.38	.040
Curaçoa	1.0300	55.0	47.3	26.60	28.50	0.10	.040
Kümmel	1.0830	33.9	28.0	32.02	31.18	0.84	.058
Peppermint	1.1429	34.5	28.6	48.25	47.35	0.90	.068
Swedish punch	1.1030	26.3	21.6	36.61	....	....	....

In recent years there has been great objection made to the use of absinthe on account of its very injurious effects, and its importation and shipment in interstate commerce were prohibited in the United States in 1912. Consult also Mew and Ashton, *Drinks of the World* (New York, 1892), and Sadtler, *Industrial Organic Chemistry* (Philadelphia, 1901).

LIQ′UID (Lat. *liquidus*). A consonant pronounced by the closure of the vocal organs greater than is required in the utterance of the closer vowels, but less than is demanded by the mute consonants. The term was originally used by Greek grammarians as early as the second century B.C. because of the smooth and flowing sound of these letters and the pliancy with which they coalesce in pronunciation with a preceding mute. Transferred into Latin as *liquidæ* (a literal translation of the Greek ὑγρά), it has since remained in use. The liquid consonants are *l, m, n, r*. But this classification is no longer adhered to by phoneticians. A somewhat similar term is the French *mouillé*, literally 'wet,' applied to the palatalized pronunciation of *l* and some other consonants.

LIQUID AIR, LIQUID HYDROGEN, ETC. See LIQUEFACTION OF GASES.

LIQ′UIDAM′BAR (Neo-Lat., from Lat. *liquidus*, liquid + ML. *ambar*, *ambra*, amber, from Ar. *'anbar*, ambergris). A genus of trees belonging to the family Hamamelidaceæ (witch-hazel family). It includes four species, distributed as follows: *Liquidambar formosana* in China, *Liquidambar macrophylla* in Central America, *Liquidambar orientalis* in Asia Minor, and *Liquidambar styraciflua* in North America. The trees are tall and remarkable for their fragrant balsamic products. *Liquidambar styraciflua*, red gum, or sweet gum, is found from Connecticut south to Florida and west to Texas and Mexico. In the South, where the tree is common, it attains a height of 100 feet or more. The timber, which is often called satin walnut in the markets, is valuable. A resinous gum exudes from the tree similar to the storax of the Orient.

LIQUIDAMBAR.

LIQ′UIDAT′ED DAMAGES. The sum agreed upon by the parties to a contract, to be paid by either in case of his default to the other, as the measure of compensation for the loss occasioned by the breach. The right of the parties to a contract to anticipate that there may be a breach by one of them, either with or without good cause, and to estimate and determine in advance what will be a fair and reasonable compensation to the injured party, is recognized and protected by the courts. The chief concern of the courts in the interpretation of agreements of this character is to determine whether the sum thus named is in fact the result of an honest effort to fix a sum which will approximately make good the loss which may be suffered in case of breach, or whether it is out of all proportion to the probable amount of damages sustained, and therefore in the nature of a penalty. In the latter case it is void, as it is deemed contrary to public policy to permit parties to stipulate for a penalty. The courts will give great weight to the intent of the contracting parties, as far as that can be ascertained by considering the language employed by them, and the surrounding circumstances which induced them to insert such a provision. It is common to fix the amount of damages for delay in case of building operations, and it is in this class of cases that the courts have been most lenient in the construction of these stipulations. The advantage of thus fixing the damages in advance is that the aggrieved party is spared the trouble and possible expense of offering proof of the items of his damages at the trial, and that the uncertainty as to what a jury might consider adequate is avoided. Generally speaking, when damages can be easily ascertained by computation merely, and the amount named as liquidated damages is greatly in excess of that amount, or where the contract is for the payment of money only, and a sum in excess of what would be the highest rate of legal interest is fixed, the courts will regard it as a penalty. The courts will not disregard such an agreement merely because the sum named will be liberal compensation for the probable loss sustained, but only when it seems grossly out of proportion to the loss. However, these agreements are regarded with suspicion. Where the intention, as expressed, is ambiguous, and there is doubt as to whether the sum is to be deemed as liquidated damages or as a penalty, the courts incline towards the latter construction. See DAMAGES; PENALTY; and consult the authorities referred to under DAMAGES.

LIQ′UIDS, GENERAL PROPERTIES OF. See HYDROSTATICS; MATTER.

LIQ′UORICE. Various shrubby plants. See LICORICE.

LIQ′UORS (Lat. *liquor*, fluid, from *liquere*, to be fluid), FERMENTED AND DISTILLED, STATISTICS AND HISTORY OF. Alcoholic liquors are naturally divided into three groups: (1) fermented liquors or wines, in which the sugar of fruit is converted to alcohol by simple exposure to the air; (2) malt liquors, such as beer, ale, porter, which, being mostly made from grains and starchy materials, require the preliminary process of malting, by which the starch is converted into sugar, before alcoholic fermentation is possible; (3) distilled liquors or ardent spirits, as brandy, whisky, gin, in which the fermented liquor, whether derived from fruits, grain, or other sugar-producing material, is treated to a further process of distillation, or vaporizing and condensing. That the industry is one of considerable importance is shown by the fact that during the year ending June 30, 1910, 1,784,553,510 gallons of malt liquors, 156,237,526 gallons of distilled liquors, and 50,000,000 gallons of wines were manufactured in the United States. This was produced by 2317 establishments, and the total product was valued at $592,550,348.

Wine Manufacture. Wine, being the product of natural forces and not requiring machinery for its production, is the oldest of the beverages and was made before the dawn of history. With the cultivation of the vine and the growth of complex tastes the industry became highly developed. The wines of Greece and Rome were prepared with greatest care and often flavored with spices and herbs. Throughout the Middle Ages and in modern times the manufacture of wine has been an important industry in most European countries. The settlers of America brought with them both a taste for wine and a knowledge of its manufacture. But early attempts to introduce this industry were unsuccessful because of failure to acclimate the European vines. The successful use of a native American grape—the Catawba—marked the beginning of this industry east of the Rockies. In California, however, foreign vines were introduced and successfully cultivated by Catholic missionaries from Mexico as early as 1771, but a century passed before wine manufacture became an important industry. Of the States east of the Rockies where wine is made, Ohio, New York, and Missouri are far in the lead. By the census of 1860 the total value of the product for the United States was $400,791, of which $155,966 was from New York and $47,275 from Ohio. By the census of 1910 the value of the product in New York was $1,816,620; Ohio, $1,303,697; Missouri, $336,809. The importance that the California industry had assumed during the 50 years between these two censuses is shown by the fact that of the total product in the United States in 1910, valued at $13,120,846, California produced an amount valued at $8,936,848. The wine product of the United States is still small as compared with that of the other wine-producing countries of the world, as is shown by the accompanying figures (the latest available), giving the estimated wine product of the world for 1912. See WINE.

ESTIMATED WINE CROP OF THE WORLD FOR THE YEAR 1912

Manufacture of Malt Liquors. The early history of this industry in the United States is described as follows in the twelfth census: "In colonial times as well as in the early decades of the nation's history, the consumption of malt liquors was relatively small and increased slowly. The wide distribution of small quantities of wine manufactured from currants or grapes, the introduction of tea, the general consumption of all classes of distilled spirits, and the household

* Since 1866 includes domestic spirits exported and returned.

This table does not include withdrawals of distilled spirits free of tax for scientific purposes and for the use of the United States government or since 1906 withdrawals for denaturation free of tax.

Totals do not include data with respect to commerce between the United States and insular possessions from 1901 to date.

NOTES. — (1) The production of domestic wines from 1871 to 1892 was estimated by the Department of Agriculture, by Mr. Charles McK. Leoser, president of the Wine and Spirit Traders' Society of New York, and other well-informed persons, and the production for 1889 (opposite the year 1890) is that officially reported by the United States Census. (2) The consumption of domestic spirituous and malt liquors was obtained from reports of the Commissioner of Internal Revenue.

† Of not more than 31 gallons. ‡ Includes fermented liquors removed from breweries for export free of tax.
§ Whisky
‖ Commercial alcohol
¶ Alcohol
** No classification
New classification made to harmonise with pure-food law.

manufacture of cider and fruit brandies, satisfied the tastes of the people, and the demand for malt liquors was of slow development. Where the demand existed at all it was for ale, porter, or stout. The manufacture of lager beer in the United States was begun about 1840. It extended with the general increase of population, the influx of German immigrants, and the cultivation of the tastes of the people for milder beverages. In 1900 its use had almost entirely superseded that of ale and porter." Since 1850 the manufacture of malt liquors in the United States has steadily and rapidly increased, the number of factories rising from 431 to 1414; the amount of capital invested from $4,072,380 to $671,158,110; and the value of product from $5,728,568 to $374,730,096. An army of nearly 66,725 wage earners are now employed in producing this enormous annual output. Owing to the nature of the raw material required, the industry is more widely spread throughout the country than that of wine manufacture. Since in this industry the transportation of the finished product is more expensive than that of the raw material, the centres of manufacture are near the place of consumption, i.e., in or near the large cities. In this respect the industry differs from the manufacture of either wine or distilled spirits, in both of which the cost of transporting the raw material is much greater than that of the finished product. In value of malt liquors produced, the States rank as follows: New York, Pennsylvania, Wisconsin, Illinois, Missouri, Ohio, New Jersey. See BEER; BREWING.

Manufacture of Distilled Liquors. The history of this industry in the United States is not characterized by the steady growth which marks the other two branches of alcoholic industries. The number of distilleries reported by the census in 1850 was 968, and, in 1910, 613. The amount of capital engaged in the industry, however, was only $5,409,334 in 1850 as against $72,450,336 in 1910, and the value of the output was $15,770,240 as against $204,699,412 in 1910. The number of employees in 1850 was about 4000, while in 1910 it was 8328. The distilleries were scattered among 27 States, among which Illinois ranked first in amount of product, Kentucky second, and Indiana, Pennsylvania, Ohio, Louisiana, Maryland, and California followed, in the order named. A large amount of distilled liquor is consumed each year in the arts and sciences and also in the manufacture of medicines. On the other hand, a large amount is produced every year in illicit distilleries, of which, of course, no record is possible. Taking these and other considerations into account, it was estimated that the quantity consumed as a beverage by the people of the United States during 1910 was about 133,500,000 gallons, or a per capita consumption of approximately 1.45 gallons.

See ALCOHOL; DISTILLED LIQUORS; RUM; WHISKY; ETC.

LIQUOR TRAFFIC. The social evils, in the shape of poverty, vice, crime, and loss of social efficiency, resulting from the widespread use of intoxicating liquor as a beverage have incited efforts in all civilized countries to restrict the practice. While the evils in question are generally recognized, there is a wide divergence of opinion as to the wise and proper method of dealing with the problem. At one extreme is a large but diminishing class of intelligent people who believe that the remedy lies only in the general diffusion of intelligence and in the elevation by moral means of the habits of the community. At the other extreme is now a larger and increasing number of people who regard the absolute prohibition and sale of intoxicating beverages as the only efficacious remedy. Between these two extremes lies the great body of intelligent public opinion, which deems it necessary that the liquor traffic shall be restricted, but doubts the efficacy or the wisdom of absolute prohibition. The temperance movement in Europe, as well as in America, has accordingly become in large measure a movement for some form of governmental interference with the sale of intoxicants.

This interference—sometimes open and avowed, sometimes disguised as a revenue measure—has taken on various experimental forms, all of which have been attended with an encouraging measure of success, but none of which, owing to the unsettled state of public opinion on the question and to the frequent changes of policy resulting therefrom, have proved wholly successful in attaining the desired end. The measures thus resorted to in the United States have been the following:

1. The segregation of the liquor traffic, confining it by statute or by municipal regulation to certain areas or excluding it from certain residential districts in cities. This method has been employed on a considerable scale in a number of Western cities, and indeed, to a limited extent, in most cities and many villages and the District of Columbia by regulations prohibiting saloons within a fixed distance from schools, churches, etc.

2. Restriction of the number of saloons or other places where liquors are sold to a fixed ratio to the population. This plan has been adopted in Massachusetts, which limits the number to one for every thousand inhabitants in the State at large, and one to every 500 in the city of Boston.

3. High license, or the imposition of a license fee or tax high enough to effect automatically a restriction on the number of saloons and to shut out the poorer and more disreputable drinking places, especially such as are the haunts of criminals and prostitutes. This plan has been widely adopted as a temporary, if not a permanent, method of dealing with the problem, generally in connection with the methods of segregation, restriction, or local option, and is employed to-day in practically all the States which have not adopted the policy of absolute prohibition. The license fee varies greatly in amount, the maximum being usually $1000 per annum (as in Alaska, Massachusetts, Ohio, and many other States) to $1500 (in the District of Columbia, New York, Rhode Island, and New Mexico) and $2000 (in Utah).

4. Local option, or the plan of vesting in counties, cities, or towns the power to determine by popular vote whether they shall be "wet" or "dry," i.e., whether the sale of intoxicating liquors shall be permitted or not. This method is now in force, along with high license, in practically all the States which have not absolutely prohibited the traffic.

Inasmuch as these methods of regulation, while often locally advantageous, have not resulted in materially diminishing the social evils at which they are aimed, the sentiment in favor of the absolute prohibition of the liquor traffic has grown enormously during recent years and now bids fair to become the dominant influence in determining the policy of the State with reference to the evil. The State of Maine was the first American Commonwealth to adopt this measure, the "Maine Law," as it has come to be known, having been enacted as early as 1846 and being still in force. Similar legislation in Vermont (1852), New Hampshire (1855), Connecticut (1854), and New York (1855), was later repealed, local-option laws having in each case superseded the prohibition law. After a generation of experimentation with the regulative measures above described, the movement for "State-wide prohibition" has revived with new force. Up to June, 1915, 14 States had adopted the policy. A movement for national prohibition resulted in the introduction in Congress of the Hobson-Shepard joint resolution to submit a constitutional amendment to the States. The vote in the House gave a majority in favor, but not the necessary two-thirds (Dec.

22, 1914). The resolution was reintroduced the next month. See Intoxicating Liquors; License; Prohibition; Temperance Movement.

LIRA, lē′rȧ (It., from Lat. *libra*, pound). An Italian silver coin, of greater or less value according to time and place. The Tuscan lira was equal to 80 French centimes; the Austrian lira, or zwanziger, was of about the same value. The present lira of Italy, a silver coin, is equal to the French franc (about $0.193), and is divided into 100 centesimi.

LIRI, lē′rē. See Garigliano.

LIRIA, lē′rē-ȧ. A town of Spain, in the Province of Valencia, and 12 miles northwest of Valencia (Map: Spain, E 3). The plain in which it stands is planted with vines and olives and also produces fruits and cereals. Near by are vestiges of the ancient Edeta. Entirely aside from this identification, the history of Liria has been long and interesting. It was taken from the Saracens by James of Aragón (1252), was captured by Peter of Castile in 1363, and belonged to the crown and had a vote in the Cortes until it was given by Philip V to Marshal the Duke of Berwick, with the title of Duke of Liria. It suffered severely in the Carlist Wars. (See Liria, Dukes of.) There are mineral springs in the neighborhood. Pop., 1900, 8839; 1910, 9034.

LIRIA, Dukes of. By royal patent of 1707 Philip V conferred upon James Fitz-James, first Duke of Berwick, who had rendered him important services as field marshal in the War of the Spanish Succession, the title of Duke of Liria and Xérica, with a grandeeship of Spain. This title descended through the male line (each generation rendering distinguished services to Spain) until Carlos Miguel Stuart Fitz-James, as seventh Duke of Berwick and seventh Duke of Liria and Xérica, inherited from his aunt (1802) the headship of the ancient house of Alba as fourteenth Duke of Alba de Tormes. Since then these two great houses have been united, and the heir to the Duke of Berwick and Duque de Alba (as the head of the house is known) assumes by courtesy the title of Duque de Liria.

LIR′IODEN′DRON. A genus of plants. See Tulip Tree.

LI′RIS. See Garigliano.

LISA, lē′sȧ, **LIZA**, lē′sȧ, **LIZITA**, lē-sē′tȧ. Names in the Spanish West Indies for various mullets. See Mullet.

LISAINE, lē′zȧn′, Battle of. An engagement in the Franco-Prussian War, which raged for three days (Jan. 15–17, 1871) on the small river Lisaine, near the French fortress of Belfort (q.v.). Gambetta, hoping to withdraw the Germans from around Paris by a diversion in southern Germany, ordered Bourbaki to threaten the enemy around Belfort and to attempt an inroad into Baden. The German general, Von Werder, retreated before Bourbaki and took up a position along the Lisaine, in order to defeat this plan. Bourbaki, with 120,000 men, made desperate efforts to drive the Germans from their position, but the latter were so strongly fortified, and the French soldiers were so weak from labored marches and lack of food, that these efforts were without avail. Surrounded on three sides by the victorious Germans, the remnants of the French army, 85,000 in number, crossed the border line into Switzerland, where they were interned until the close of the war. Consult Belin, *Le siège de Belfort* (Paris, 1871).

LISBOA, lēs-bō′ȧ, João Francisco (1812–63). A South American author, born at Iguará, Maranhão, Brazil. He studied at one of the colleges at Rio de Janeiro and became a journalist. He edited various newspapers, including the *Cronica* (1838–41), and the *Jornal de Timon* (1852–58), which he wrote as well as edited himself. It contained historical and political papers criticizing both sides, although he was of the Liberal party. He was clerk to the Secretary of the government from 1835 until 1838, and took an active part in politics. Afterward he devoted himself to historical research and went to Lisbon, Portugal, where he died. His distinguished services had been rewarded with the cross of Commander in the Order of Christ, of Brazil. His works include: *Vida do Padre Antonio Vieira* (1874); *Historia do Maranhão* (1850); *Obras completas, antecedidas de uma noticia biographica pelo dr. Antonio Henriques Leal* (4 vols., 1864–65); and several in manuscript. The aforesaid biographical notice may also be found in A. H. Leal, *Pantheon maranhense*, vol. iv (Lisbon, 1874).

LISBON, lĭz′bŭn (Portug. *Lisboa*). The capital of Portugal and of the Province of Estremadura, situated on the north shore of the estuary of the Tagus, 7 miles from the ocean; lat. 38° 43′ N., long. 9° 11′ W. (Map: Portugal, A 3). The estuary is here about 1½ miles wide, but immediately above the city it widens into a tidal lake from 4 to 8 miles wide and about 11 miles long, forming one of the best harbors of Europe, with deep water both in the lake and through the narrow entrance, which is defended by fortifications. The city stretches along the shore of channel and lake for 5 miles; it extends inland for over 3 miles, and rises in a succession of terraces, its houses mingling with the green foliage of its parks. The surrounding district is dotted with villas. The city proper consists of four municipal districts (*bairros*): the old town, the *Alfama*, in the east; the new town, or the *Cidade Baixa*, in the middle and on the low ground next to the Tagus; the *Bairro Alto* on the heights to the north; and *Alcántara* in the west. It is not fortified on the land side, and straggles off in long avenues bordered with villas towards the plateau of Estremadura.

The old town is built around a hill surmounted by the Castello de São Jorge, an old Moorish castle now used as barracks and military prison. This was the only part of the city not destroyed by the great earthquake of 1755. It still has a number of Moorish and Roman remains, and its streets are narrow and crooked, besides being steep and ill-paved. There are a large number of churches in this section, many of them very old, especially the Sé Patriarchal, or cathedral, founded in 1150. It was destroyed by an earthquake in 1344, rebuilt in 1380, and damaged by the earthquake of 1755; later it suffered from fire. After restoration the only parts wholly of the fourteenth century were choir and façade. The new town, which is west of the Alfama and was built up subsequent to the great earthquake, is regularly laid out with wide streets crossing at right angles, and traversed by numerous street railways. Facing the river front is the largest square in the city, the Praça do Commercio, surrounded by public buildings and containing a large statue of King Joseph I in the centre. On the west side of the square are the general post office and the naval arsenal; on the east are the exchange and the customhouse; and on the north are two ministerial buildings and the city hall. From this plaza extend eight parallel streets to the north, the one in the centre being entered through a triumphal arch, and all of them terminating at the Praça de Dom Pedro Quarto, with a statue of that monarch and two bronze fountains. Running northwest from the praça is the largest and finest promenade in the city, the Avenida da Liberdade, which is 1 mile long and 300 feet wide, with a double row of shade trees along the middle. It passes near the Botanical Garden, one of the finest in Europe, containing a superb collection of tropical plants, and inclosing also the polytechnic school and the astronomical observatory. Half a mile to the west is the beautiful Estrella Garden, opposite the Estrella Church, the most conspicuous building in the city, with a white marble cupola and two bell towers that can be seen for many miles around. Still farther to the west, and within the limits of the bairro of Alcántara, stands the palace, an eighteenth-century edifice, with a fine park, the Tapada das Necessidades; and from here the road crosses the Alcántara River into the suburbs of Belem and Ajuda, forming the extreme western part of the city.

Lisbon has a medical school (1836), a polytechnic school (1837), a normal school, several high schools, schools of commerce, agriculture, and navigation, academies of art and music, several museums, scientific academies and societies, and the national public library, containing over 400,000 volumes, 15,000 manuscripts, and 40,000 coins and medals. Among public works should be mentioned the two aqueducts, one 15, the other 70 miles long, which supply the city with abundant and pure water. The sewerage system is excellent, and the city is one of the cleanest in Europe. It has manufactures of jewelry, musical instruments, woolen, cotton, and silk fabrics, gloves, hats, shoes, paper, soap, and chemicals, and various other articles; it has also sugar refineries, iron foundries, and machine shops. Commercially Lisbon has the natural advantages of harbor and geographical position that should make it a leading centre of traffic. Its trade is principally with England, Brazil, and the African colonies. The chief imports include grain, sugar, cotton, tobacco, coal, petroleum, and timber; the chief exports, cork, wine, olive oil, salt, fruits, and fish; besides, Lisbon is an important port of transit for colonial wares. The largest vessels can enter the Tagus; on the right bank are extensive quays and two graving docks, on the left bank government and private docks. The city has five railway stations. There is a railway bridge across the Tagus. The city is lighted by electricity and gas. In 1901 cable cars and mule trams were superseded by a system of electric street railways. The aggregate de facto population of the four bairros comprising Lisbon was 301,206 in 1890, 356,009 in 1900, and 435,359 in 1911 (census of December 1). The inhabitants of 10 years of age and over in 1911 numbered 361,941, and of these 153,745 could neither read nor write.

Lisbon was called *Olisipo* by the ancient Lusitanians; the Visigoths changed the name to *Olisipona*, and the Moors to *Lishbuna*, whence the present name. It is said to have been founded by the Phœnicians, and was the flourishing capital of Lusitania when first visited by the Romans. It was taken by the Moors in 716 and held by them till 1147, when it was recaptured by Alfonso I with an army of Crusaders, mostly Englishmen. During the centuries of Portuguese exploration Lisbon rose to a high position of commercial supremacy. It lost this position during the Spanish occupation (1580–1640). On the 1st of November, 1755, the city was visited by a frightful earthquake, which laid the greater part of it in ruins and killed 30,000 to 40,000 persons. Its rapid recovery was due largely to the energy of the Prime Minister, the Marquis of Pombal. In 1807–08 the city was occupied by the French.

LISBON. A town in Androscoggin Co., Me., 7 miles south of Lewiston, on the Maine Central Railroad (Map: Maine, B 4). The chief industries are represented by cotton, wool, and paper mills. Farming, too, is engaged in extensively. Pop., 1900, 3603; 1910, 4116.

LISBON. A village and the county seat of Columbiana Co., Ohio, 24 miles (direct) south of Youngstown, on the Beaver River and on the Erie, the Youngstown, and Ohio River, and the Pittsburgh, Lisbon, and Western railroads (Map: Ohio, J 4). It has a public library and is the centre of a productive region engaged in farming, coal mining, and sheep raising. There are copper mills and manufactories of sewer pipe, pottery, etc. Pop., 1900, 3330; 1910, 3084. Lisbon was the birthplace of Mark A. Hanna.

LISBURN, lĭz′bûrn. A market town and cathedral city on the Lagan, in the County of Antrim, Ireland, 8 miles south-southwest of Belfast (Map: Ireland, F 2). It is clean and well ordered, with a convenient market and considerable manufactures of fine linens and damasks; there are also large rope works, net factories, and dye works. Its parish church is the cathedral of the Protestant diocese of Down, Connor, and Dromore. There is a fine park, known as Castle Garden, which was presented to the town by Sir Richard Wallace in 1888. A noteworthy feature of the town is the monument to Jeremy Taylor, who was Bishop of that see and died at Lisburn in 1667. Lisburn originated in the erection of a castle, in 1610, by Sir Fulk Conway, to whom the manor was assigned in the settlement of James I; but its importance dates from the settlement of a number of Huguenot families who, after the revocation of the Edict of Nantes, introduced the manufacture of linen and damask, after the machine-fabricating methods employed in the Low Countries. Lisburn gives the title of Earl and Viscount to the Vaughan family. Pop., 1901, 11,460; 1911, 12,388.

LISCO, lĭs′kō, EMIL GUSTAV (1819–87). A German theologian. He was born in Berlin and was educated there and at Bonn. From 1845 to 1887 he was pastor of different churches in Berlin and became one of the most distinguished of its liberal preachers and theologians. He took a prominent part in the liberal Church movement and was one of the founders of the Berlin Union and the Union of the German Protestants. In 1872 he was severely reprimanded by the Consistory for his publication of *Legendenhafte Bestandteile in dem apostolischen Glaubensbekenntnis* (1872). He also published *Berlin und der Protestantismus* (1870–73) and *Der Glaube an den Heiligen Geist* (1860).

LISCOW, lĭs′kō, CHRISTIAN LUDWIG (1701–60). A German satirist, born at Wittenburg, Mecklenburg-Schwerin. He studied law at the universities of Rostock, Jena, and Halle. In 1741 he entered the Saxon civil service, where he attained the rank of counselor in 1745. Liscow is considered one of the best German prose writers before Lessing. He attracted much attention by his essay *Die Vortrefflichkeit und Notwendigkeit der elenden Skribenten* (1736). He republished his different satirical writings collectively, under the title *Sammlung satirischer und ernsthafter Schriften*, in 1739. Consult B. Litzmann, *C. L. Liscow in seiner literarischen Laufbahn* (Hamburg, 1883).

LISGAR, lĭz′gar, first Baron. See Young, Sir John.

LISIEUX, lē′zyẽ′ (Lat. *Noviomagus*). A town in the Department of Calvados, France, situated in the valley of the Touques, 118 miles west of Paris (Map: France, N., F 3). The church of St. Pierre of the twelfth and thirteenth centuries is said to be the oldest Gothic church in Normandy. It was built by the Bishop of Beauvais, one of the judges at the trial of Joan of Arc, to atone for his condemnation of the maid. The church of St. Jacques (1496–1501) contains fine mural paintings, stained glass, and wood carving. The episcopal palace, built during the seventeenth and eighteenth centuries, and now used as a courthouse, contains a fine hall and a small collection of modern French paintings. Lisieux has numerous private houses in Mediæval and Renaissance styles and remains of an old Roman building. The chief educational institutions are the communal college, a seminary, and a library of 24,000 volumes. Textiles, leather, lumber, metal wares, and machinery are the chief manufactures, and the trade is in agricultural and dairy products and cattle. Prior to the conquest of the Gauls Lisieux was known as Noviomagus, the capital of the Lexovii. It was the seat of a bishop from the sixth century to 1790. Pop., 1901, 16,084; 1911, 15,948.

LISLE, lĭl, Alice (c.1614–85). An Englishwoman, wife of the regicide John Lisle. On the charge of harboring John Hickes, a traitor, whom she knew only as a Nonconformist minister, she was tried before Judge Jeffreys, who forced the jury to convict her. She was condemned to be burned, but this sentence was commuted, and she was beheaded Sept. 2, 1685. On the scaffold she gave the sheriff a paper denying her guilt, and it was published in *The Dying Speeches of . . . Several Persons* (1689). By an act of Parliament passed at the beginning of the reign of William and Mary her attainder was reversed on the ground that the verdict against her had been extorted by violence. Consult Howell, *State Trials*, and H. B. Irving, *The Life of Judge Jeffreys* (New York, 1898).

LISLE, lēl, Charles Marie Leconte de. See Leconte de Lisle, C. M.

L'ISLE, Claude Joseph Rouget de. See Rouget de l'Isle, C. J.

LISLE, Guillaume de (1675–1726). A French geographer, born in Paris. He devoted himself to the study of cartography from an early age and produced a large number of maps marked by a correctness of treatment far above the general geographical knowledge of the time. Besides purely geographical works he published a large number of maps in connection with editions of voyages of discovery and exploration. In 1702 he was elected to the Académie des Sciences and in 1718 was made Royal Geographer.

L'ISLE ADAM, Philippe Auguste Mathias, Comte de Villiers de. See Villiers de l'Isle Adam, P. A. M.

LISMORE, lĭz-mōr′. An island of Argyllshire, one of the Inner Hebrides, 6 miles from Oban (Map: Scotland, C 3). It is noted for its antiquities: the parish church, formerly the choir of a cathedral; the remains of the Achinduin Castle, the ancient residence of the bishops of Argyll; and the ruins of Castle Rachal, a Scandinavian fort. It is chiefly noted for the "Book of Lismore," a collection of early Gaelic poems, made by James M'Gregor, dean of Lismore, early in the sixteenth century. Pop., 1901, 500; 1911, 407.

LISMORE. A town and episcopal see in County Waterford, Ireland, 43 miles west-southwest of Waterford (Map: Ireland, D 7). Lismore, one of the best-kept towns in Ireland, is situated on a bluff rising abruptly from the river Blackwater, which is spanned by a stone bridge erected in 1775. On the brink of this bluff and facing the river is Lismore Castle, erected by King John in 1185 but extensively restored in 1793 by the dukes of Devonshire, to whom it belongs. The Protestant cathedral of St. Carthagh contains many interesting sepulchral slabs of the ninth century. It was restored in 1633 and the present limestone spire was erected in 1827. The town, which is the centre of the salmon fisheries of the Blackwater, is famous as the birthplace of Robert Boyle the philosopher and Congreve the dramatic poet. It grew up around the abbey founded by St. Carthagh in the seventh century, which was so famous as to be styled the "luminary of the western world." It was besieged in 1641, when it suffered severely, and again in 1643 and 1645. Pop., 1911, 1583.

LISOLA, lē′zō′lȧ′, François Paul, Baron (1613–75). An Austrian diplomat, born at Salins in Franche-Comté. He began his diplomatic career in 1638. In 1643 he went to London as Ambassador to persuade Charles I to reinstate the Count Palatine. In 1655 he was sent to Sweden to effect peace with the Poles, but having failed to attain this, he induced the Emperor Ferdinand III to conclude an alliance with them. When Ambassador in Poland he brought about the reconciliation of that country with the Elector Frederick William of Brandenburg and at the same time established a union between this Prince and the Emperor. From Poland he was transferred to The Hague. In 1660 Lisola took part in the peace negotiations at Oliva, and after 1667 his great effort was to form a coalition against Louis XIV, whose plans he described and denounced in his famous pamphlet, *Le bouclier d'état et de justice contre le dessein de la monarchie universelle* (1667). It was also chiefly due to his exertions that an alliance was established between Austria and Holland in 1672, in which union Spain also joined the following year. A more detailed account of the life and work of Lisola is to be found in Reynald, "Le Baron de Lisola; sa jeunesse et sa première ambassade en Angleterre," in the *Revue Historique* (vol. xxvii, Paris, 1885), and Pribram, *Franz Paul Freiherr von Lisola und die Politik seiner Zeit* (Vienna, 1894).

LIS PEN′DENS (Lat., suit pending). In law the pendency of an action or other legal proceeding, comprehending the entire period of a litigation from the institution of the suit by the original process (summons, bill, or libel) to the execution of the final judgment. A person designated by a court to act for and represent an infant or lunatic during the pendency of a suit is known as a guardian *pendente lite*. Specifically, the phrase *lis pendens* has in English and American legal procedure come to be employed to denote the suspension of the right of the owner of specific property or of a claim to alienate or encumber the same during the pendency of an action in which the title thereto is being determined. The doctrine is a very old one in the English law and was early expressed in the maxim *pendente lite nihil innovetur* (pending the action nothing may be changed). It was adopted to prevent the intervention of new rights to property in dispute which might complicate and prolong the litigation. As was said by an eminent English judge: "The law does not allow litigant parties to give to others, pending the litigation, rights to the property in dispute, so as to prejudice the opposite party." If this were not so, there would be no certainty that the litigation would ever come to an end, as a mortgage or sale made before final decree to a person who had no notice of the pending proceedings would otherwise confer on him a right of property which would render a new suit necessary or might even defeat the purpose of the pending suit. The doctrine embodied in the foregoing statement is commonly put in the mistaken form that a *lis pendens* is notice to everybody dealing with the property in suit of the controversy respecting the title. In order to avoid the inconveniences and hardships of this doctrine it is now everywhere provided by statute that, in a suit affecting the title to real estate, a litigating party, in order to protect his rights, must file in the public record office a written notice of the pendency of the action, which notice (also known as a *lis pendens*) must specify the title and nature of the action and the date when it was commenced, and set forth a description of the property sought to be protected against sale or encumbrance. The registration of such notice holds good for a definite period of time specified in the statute. It has been held that a *lis pendens* so filed and registered is only notice of matters charged in the statement of claim and not also of every equity which might possibly arise out of the matters in question in the action. The most frequent use of the *lis pendens* in this sense of the term is by mortgagees when instituting suits for the foreclosure of mortgages on real estate. See SUIT; FORECLOSURE.

LIS'SA (anciently Lat. *Issa*, Slav. *Vis*). An island in the Adriatic Sea, off the Dalmatian coast, belonging to Dalmatia (Map: Italy, F 3). It is 10½ by 4½ miles and has an area of 38 square miles. Its shores are steep and rocky and it is accessible at only a few bays. The soil is not fertile. The chief products are wine and oil. The sardine fisheries are important. The population of the island in 1900 was 9918. Its two harbors are strongly fortified. Lissa, or San Giorgio, on the northeast shore, is the principal town and seaport, with a population of 5261. Issa was an ancient Greek colony from Lesbos; in the fourth century B.C. colonists came from Paros. The people helped the Roman general Duilius (q.v.); they aided the Romans also in the war with Macedon (215–211 B.C.). Issa became an important naval station for the Roman fleet. By the tenth century the Venetians had a foothold in the island. In Napoleon's time the French held the island till 1811; these years brought great prosperity to Issa. In 1812–15 the English held the island; in 1815 it was ceded to Austria. Off Lissa the Austrians under Admiral Tegethoff defeated the Italians under Admiral Persano July 20, 1866; this was the first battle at sea between modern ironclad fleets propelled by steam. Lissa was bombarded and captured by an Anglo-French fleet in the European War which began in 1914. See WAR IN EUROPE.

LISSA (Polish *Lészno*). A town in the Province of Posen, Prussia, 47 miles by rail from Posen (Map: Prussia, G 3). It has a palace with a park, an old town hall, a Gymnasium, and a Roman Catholic teachers' seminary. It manufactures wines, liquors, bricks, shoes, machinery, lumber, snuff, and cigars, and handles a considerable trade in cereals and cattle. Pop., 1900, 14,282; 1910, 17,156. The town formerly belonged to the Polish noble family of Leszczynski and became in the seventeenth century the centre of the Bohemian Brothers, who transferred there their educational institutions and their archives.

LISSAJOUS (lē̇'sȧ'zhōōz') **FIGURES.** A name given to certain phenomena designed to show optically the composition of vibratory motions. On April 6, 1857, Jules Antoine Lissajous presented to the Academy of Sciences in Paris a memoir on the optical study of vibratory movements, wherein he set forth that series of peculiar curves which have since borne his name, and which are generated by the combination of two vibrations taking place in the same plane, but at right angles to each other. (This work was anticipated in America by Nathaniel Bowditch, of Salem, in 1815.)

Suppose a body is vibrating back and forth between *E* and *W* (Fig. 1) in simple harmonic motion, when an impulse is given to it which alone would set it into similar vibration between *N* and *S*. Assume that the time of vibration of the two motions is the same, then the result of their combination will depend upon the relative "phase" of the two vibrations. Several characteristic cases may be considered as typical of the real infinity of possible variations. If the body tend to start from *O* towards *E* at the same instant that it tends to start from *O* towards *N*, then its real motion would be along the diagonal of the rectangle on *OE* and *ON*, and the resulting vibration would be as shown in Fig. 2 (*a*). This is the case where both harmonic cycles start at the same instant from the position of equilibrium, *O*; i.e., the difference of phase is zero. If it tend to start from *O* towards *N* and *W* simultaneously, then the resulting vibration will be shown at Fig. 2 (*e*). In this case the *EW* motion would have executed a half cycle when the *NS* commences; i.e., the phase difference is one-half.

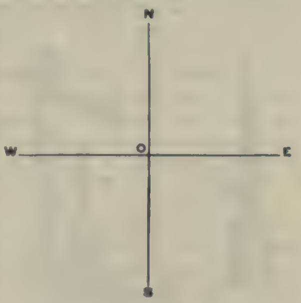

FIG. 1.

For a phase difference of one-quarter the body would be at *E* when the *NS* motion starts, and the result is shown in Fig. 2 (*c*). A phase difference of three-quarters would put the body at *W* when the other motion starts, and the figure would be the same as *c*, except that it would circulate in the opposite direction.

The result of a phase difference of one-eighth is shown in *b*, and that of three-eighths in *d*. If the amplitude of the two motions be the same, it is evident that Fig. 2 (*c*) would be a circle. A small weight or plumb bob hanging upon a string serves very well to illustrate the above forms of compound vibration.

FIG. 2.

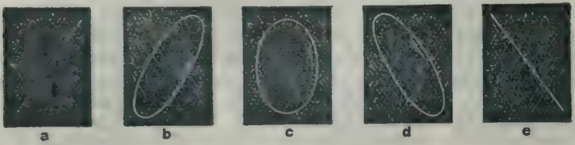

FIG. 3.

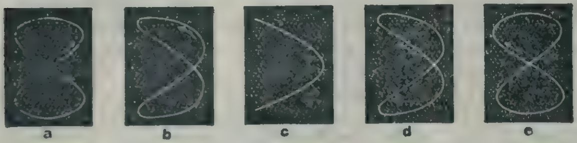

FIG. 4.

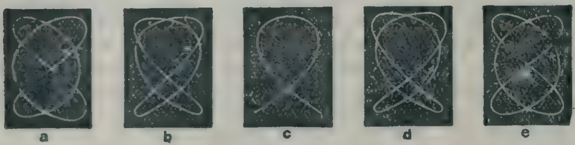

When the rates of vibration or periodic times of the two components are unequal, much more complex results are produced, which, however, reduce to comparative simplicity when the rate of one bears a simple ratio to the rate of the other. When the two rates are in the ratio of 1 to 2, there results a series of curves some of which are shown in Fig. 3, for phase differences of one-eighth, one-fourth, three-eighths, and one-half of the *EW* motion. Similarly Fig. 4 shows the corresponding curves when the rates of vibration are in the ratio of 2 to 3.

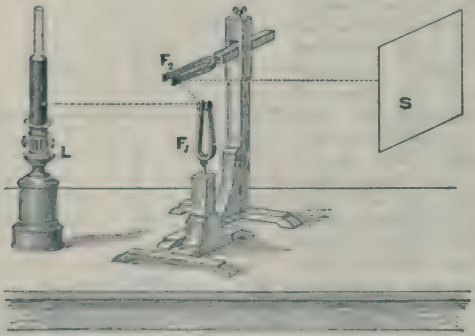

FIG. 5.

Lissajous attached a small mirror to one prong of each of two tuning forks of the same pitch. One fork is mounted vertically (F_1, Fig. 5) and the other horizontally (F_2). A ray of light from the lamp *L* is made to fall first on the mirror of the vertical fork, thence upon that of the horizontal fork, and finally on the screen *S*. If F_1 alone vibrates, then the spot of light on the screen will move up and down, owing to the tilting of the mirror on that fork. If F_2 is the only one in motion, the spot will move horizontally; and finally, if both vibrate simultaneously, then a combination curve will be exhibited, similar to some one of the forms of Fig. 2. If the two forks have different rates of vibration, then complex curves will appear; if one is the octave of the other, it will be of the class of Fig. 3; and Fig. 4 would be given by two forks having the interval of the fifth. In another form of apparatus for the same purpose the forks are replaced by two steel springs the rates of which can be varied by their length and by a small adjustable weight. Fig. 6 illustrates another method of showing these forms of vibration. The plumb bob *D* is free to swing perpendicular to the plane of the paper around the line *AB* with an effective length of the pendulum of *CD;* in the plane of the paper it can only swing around *E* with the effective length *DE*. By means of the sliding clamp *E* it is possible to adjust the two rates of vibration to definite ratios, and then the bob *D* will execute some one or all of the above curves. Many other methods have been devised for showing or drawing these curves.

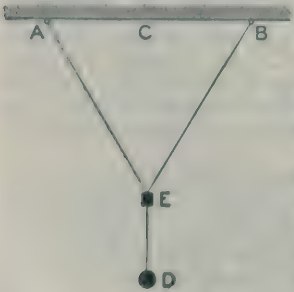

FIG. 6.

LIST, lĭst, FRIEDRICH (1789–1846). A German economist. He was born at Reutlingen in Württemberg. He was the son of a well-to-do tanner, but, as he had no taste for his father's trade, he entered the public service as a clerk and rose rapidly until in 1816 he attained the position of ministerial undersecretary. In 1817 he was appointed professor of political economy at Tübingen, but with the fall of the ministry which he supported he was forced in 1819 to resign his professorship. He was elected member of the Diet of Württemberg, but was expelled in 1822 for his censure of the acts of the government and was condemned to 10 months' imprisonment. He escaped, however, seeking refuge successively in Baden, Alsace, and Switzerland. In 1825 he came to Pennsylvania, where he tried farming, but soon abandoned it to become editor of a German paper in Reading. In 1827 he published a pamphlet entitled *Outlines of a New System of Political Economy*, in which he defended the doctrine of protection. The discovery of coal upon his property placed him in easy circumstances, and he turned again towards Germany, having received an appointment as United States Consul at Hamburg. But on his arrival in Europe in 1830 he found that the Senate had failed to confirm his appointment, and though about 1833 he was appointed Consul at Leipzig, he was *persona non grata* to the Saxon government and held the post for a short time only. At this time he was much interested in the establishment of railroads, and his insistence upon their advantages led to the building of the road between Leipzig and Dresden and contributed to the further development of the German system. He was tireless in his advocacy of protection and railroads and in the formation of associations of manufacturers for the cultivation of the influence of this class. In 1837 he went to Paris, where he wrote several letters for the Augsburg *Allgemeine Zeitung*, which were published in 1841 in a volume under the title of *Das nationale System der politischen Oekonomie.* In 1843 he established at Augsburg the *Zollvereinsblatt*, in which he advocated a national commercial system and a national fleet. He visited Austria and Hungary in 1844 and England in 1846, for the purpose of forming a commercial alliance between Germany and that country, in which his efforts were not successful. Depressed by the failure of his plans, the loss of his health and property, he shot himself in a fit of insanity. For his biography, consult: Goldschmidt (Berlin, 1878) and Jentsch (ib., 1901); also *Friedrich List, ein Vorläufer und ein Opfer für das Vaterland* (Stuttgart, n. d.; anonymous). See also article "Friedrich List" in Palgrave, *Dictionary of Political Economy* (London, 1894–99).

The chief contribution of List to economic thought is contained in *Das nationale System der politischen Oekonomie*, translated by S. S. Lloyd (new ed., 1905). In this work he emphasizes the idea that the economic policy of a nation should be such as to develop all of its resources, thus placing it in a position of independence. To this end he defended a protective system as necessary for a nation which has not developed its industry and commerce, although he regarded free trade as the goal towards which all nations should tend. He advanced few ideas in defense of protection which had not already been advanced by Alexander Hamilton, with whose work he was presumably familiar.

LISTA Y ARAGÓN, lē′stȧ ē ä′rȧ-gōn′, Alberto (1775–1848). A Spanish mathematician, educator, journalist, poet, and critic, born in Ariana, near Seville. Educated at the University of Seville in the humanities and theology, he showed wonderful ability in mathematical studies and became professor of mathematics at the age of 15 and six years after taught in the College of San Telmo. He became a priest at the age of 20. In 1808 he received the chair of rhetoric and poetics in the University of Seville and showed political independence in his *Semanario patriótico.* But when the French left Spain in 1813 Lista had to go, too, and did not return until 1817, when he was pardoned. In 1820 he founded and became head of the College of San Mateo, but his teachings were too liberal to be acceptable to the church, and he was again forced to leave the country in 1823, and the college was closed. He was recalled in 1833 and was made editor of the *Gaceta de Madrid*, and in 1837 professor of higher mathematics at Madrid. While at Madrid, he helped found the *Ateneo Científico, Literario y Artístico*, whose lecture courses often represent the most advanced instruction to be found in the city. Then he spent two years in the College of San Felipe Neri in Cadiz and in 1840 retired to Seville. He was incalculably influential with all the leaders of the younger generation in Spain. His *Poesías* (1822 and 1837) mark him as one of the greatest Spanish lyrists of the early part of the century. His *Canto del esposo*, an imitation of the Song of Solomon, is probably the best of his lyrics. As a critic, he showed a classic taste and a clear and correct style in *Ensayos literarios y críticos* (1844) and *Lecciones de literatura dramática española* (1839). He collected *Trozos escogidos de los mejores hablistas castellanos en prosa y verso;* rewrote Ségur's *Histoire universelle*, under the title *Curso de historia universal;* continued (1828) the *Historia de España*, written by Mariana and Miñana; and wrote a *Tratado de matemáticas puras y mixtas.*

LIS′TER, Joseph, first Baron (1827–1912). An English surgeon, father of modern antiseptic surgery. He was born, April 5, 1827, at Upton, Essex, the son of Joseph Jackson Lister. His early education was gained at schools for Friends. Entering University College, London, he took his degree of arts in 1847 and in medicine in 1854, and became fellow of the Royal College of Surgeons, London, in the same year, and of the Royal College, Edinburgh, in 1855. He studied at the University of Edinburgh in 1856, and at Edinburgh Royal Infirmary became assistant surgeon to Dr. James Syme (q.v.), whose daughter he married. He was thereafter successively professor of surgery at Glasgow (1860–69), professor of clinical surgery at Edinburgh (1869–77) and professor at King's College Hospital, London (1877–93). In 1878 he was appointed sergeant surgeon to Queen Victoria. Lister's earliest labors were in histology. His first investigations were directed towards proving the existence of ordinary unstriped muscle fibres in the iris. He made in addition many important observations on the early stages of inflammation and the coagulability of the blood. From the first he taught that pus in wounds was due to the decomposition of blood and serum, brought about in some way by the atmosphere, and insisted on scrupulous cleanliness and the use of deodorant solutions in his surgical wards. Before this carelessness of such precautions had characterized all hospitals. It was not until Pasteur in 1862 put forward his theory on fermentation and putrefaction that Lister fully realized that the formation of pus was due to bacteria. He at once set himself to apply the principles of antiseptics to the treatment of wounds, and the development of those principles revolutionized modern surgery. Lister was the recipient of many honors at home and abroad. In 1880 both Oxford and Cambridge conferred the degree of LL.D. upon him; he was made Baronet in 1883 and a peer in 1897, held the presidency of the Royal Society from 1895 to 1900 and of the British Association for the Advancement of Science in 1896, and in 1902 was appointed an original member of the Order of Merit. He died Feb. 10, 1912. Lister was a lucid thinker and writer. His many important papers appeared first in medical journals, notably the London *Lancet* and the *British Medical Journal*, and later were published in monograph form and as *The Collected Papers of Joseph, Baron Lister* (Oxford, 2 vols., 1909). The subjects treated include: the structure of muscle and nerve tissues, inflammation, coagulation of the blood, antiseptics (a world-famous series of essays), ligature of arteries, amputation, and anæsthetics (in Holmes's *System of Surgery*), etc. Consult, for an account of Lister's life, "Symposium of Papers Read before the Toronto Academy of Medicine" (Toronto, 1912); for an estimate of his importance, C. W. Saleeby, *Surgery and Society: A Tribute to Listerism* (New York, 1912); G. T. Wrench, *Lord Lister: His Life and Work* (ib., 1913). See Antiseptic.

LISTER, Joseph Jackson (1786–1869). An English microscopist, father of Joseph, first Baron Lister. He was born in London, assisted his father in the wine trade, and studied independently the mathematical and optical sciences.

In 1824 he made his first improvement in the achromatic microscope, and by 1830 he had worked out the principle of construction of the modern compound microscope—an invention that revolutionized scientific study. He aided A. Ross in 1837 in the invention of his famous ⅛-inch object glass, and by his advice gave invaluable assistance to other opticians in the construction of microscopes. Lister's law of aplanatic foci remained the underlying principle of microscopic science. He described some of his achievements in papers contributed to the *Philosophical Transactions*.

LIS′TON, JOHN (c.1776–1846). An English comic actor, of whose early history nothing is known, save that he studied at Soho under Dr. Barrow. He taught school for a time, was entirely unsuccessful in his first appearance on the stage as an amateur, and after some experience in tragic parts, playing at times with Mrs. Siddons, he discovered his comic powers. Despite his nervous and melancholy nature, he was very successful in old-man rôles and afterward as a clown. His dancing was good, and gradually he made himself a favorite with the London audiences. In 1823 he removed from Covent Garden to Drury Lane and in 1837 retired from the stage. During his last years his mind failed rapidly. Liston's gravity of deportment added much to his comic force, and he was highly praised by Lamb, Matthews, Colman, and by Leigh Hunt, who considered his rustics much better than his old men. The best rôles of Liston were Paul Pry, of which his treatment has become a tradition, Polonius, Slender, Bottom, Bob Acres, Bombasto Furioso, Apollo Belvie in Hook's *Killing No Murder*, Jacob Gawky in *The Chapter of Accidents*, and Grizzle in *Three and Deuce*. His wife, Miss Tyrer, whom he married in 1807, was a tiny woman, famous for her Queen Dollalolla in O'Hara's *Tom Thumb*.

LISTON, ROBERT (1794–1847). A Scottish surgeon, born at Ecclesmachan, in Linlithgowshire. He studied anatomy at Edinburgh and was made a surgeon to the Royal Infirmary. In 1835 he became professor of clinical surgery at University College, London. The skill and the rapidity with which he performed serious operations acquired for him a wide European reputation and an extensive surgical practice in London. His most important works are his *Elements of Surgery* (1831) and *Practical Surgery* (1837), the latter of which passed through several editions.

LISTOWEL, lis-tō′el. A town of Perth Co., Ontario, Canada, on the Maitland River, and on the Grand Trunk and Canadian Pacific railways, 60 miles by rail north-northeast of London (Map: Ontario, D 6). It contains a business college. Its manufacturing establishments include two builders' factories, chair and furniture factories, flour and oatmeal mill, creamery, knitting mill, and cigar factory. The town owns its water works and electric-lighting plant. Pop., 1901, 2693; 1911, 2289.

LISZT, list, FRANZ (1811–86). A famous Hungarian pianist and composer. He was born at Raiding, near Oedenburg, in Hungary, Oct. 22, 1811, and began his musical education at the age of six years. After three years' instruction he surprised his friends by playing a difficult concerto in public. The evidences of his genius were so patent that his father organized further concerts, which not only enhanced the boy's musical reputation, but gained for him many important friends and patrons among the Hungarian nobility. It was by means of their financial support that the young pianist was enabled to spend six years, completing his education, at Vienna, to which city his family removed in 1821. His teachers were the celebrated Czerny (piano) and Salieri (theory), men of strong artistic personality, who undoubtedly supplied the ballast that enabled him to resist the musical trickery in composition which at first beset his work. After a few public concerts in 1823, he and his father journeyed to Paris, with the view of securing for the boy admission to the Paris Conservatory, which, however, was refused him, owing to an old rule which excluded all foreigners. He, however, studied theory for a time under Paer and Reicha. His first operetta, *Don Sancho ou le château de l'amour*, was produced in 1825. Two years later his father died, upon which he gave up his concert work and settled as a teacher in Paris. Contemporary critics described him as "a pianist, the most extraordinary and fascinating ever known, and one of the most wonderful of improvisators." His early piano compositions were in the style and fashion of the period and were largely paraphrases upon popular or fashionable operas, in which art was frequently sacrificed to a sort of trickery, whole passages being so written as to be practically impossible to any one but himself. He met with immediate success as a teacher, the aristocratic patrons and friends of his boyhood rallying to him and enabling him to satisfy every social as well as musical ambition. The appearance of Paganini in Paris in 1831 inspired him to become as great a virtuoso on the piano as that master was on the violin. He was of a peculiarly impressionable temperament and was in turn strongly affected by the political happenings of the period, the ceremonialism of the Church, the genius of Beethoven, Weber, Chopin, Berlioz, Schumann, and Wagner; besides which he experienced several affairs of the heart, the most serious of which was his *liaison* with the authoress "Daniel Stern" (the Countess d'Agoult). Together they retired to Geneva (1835), where three children were born to them, two daughters and a son. Cosima, the youngest of the daughters, married first Hans von Bülow (1857), and, after separating from him in 1869, became the wife of Wagner, of whom her father was a mighty champion. In 1839 he reappeared in public with signal success, his only serious competitor being Thalberg (q.v.), whom he easily outrivaled. In 1849 he became kapellmeister to the Grand Duke of Weimar, a post which he relinquished in 1861. Four years later he took minor orders in the Catholic church and was subsequently known as the Abbé Liszt. During his period of service at Weimar occurred the really great events of his life.

In 1847 he had met the Princess Karoline Sayn-Wittgenstein, who united her life to his and induced him to renounce the career of the virtuoso. Their residence in Weimar, the Altenburg, became the centre of musical activity of almost all the younger artists who were in sympathy with the newest tendencies. The first performance of *Lohengrin* in 1850 under Liszt's direction marks the beginning of that effective propaganda for the works of Wagner which culminated in the establishment of the Bayreuth festivals. Here Liszt was enabled to discover, help, and introduce many artists of whom the world came to be proud; he advanced most thoroughly the school of music to which he belonged, and which has since been described in the history of music as the New German school, whose characteristic was a freedom from the old classical rules of tonality and form. Here also he began his second period of composition, by which alone he is to be judged as a composer. His work was now characterized by his own individuality as a creative artist and marked by the inherent mysticism of his nature.

He originated the form of the *Symphonic Poem* (q.v.), which became the most important factor in the development of modern programme music. It is not a continuation of the symphony, but an entirely new form, transferring the principles of Wagner's dramatic style into the realm of pure instrumental music. He also presented notable works of Raff, Schumann, Cornelius, and Berlioz. In fact, he became the champion of all new works of merit. In 1875 he was elected president of the Hungarian Academy of Music at Pest, between which city, Weimar, and Rome he spent the last few years of his life. With the passing of time critical musical opinion has come to be widely divergent regarding the value of his work and his place in the list of great composers; but, contradictory as the differing estimates have been, he is unhesitatingly conceded to have been a man of genius. To-day the consensus of the best authorities is that Liszt failed to realize his lofty ideals as a composer because of lack of real power of thematic invention. As a pianist, he has never been excelled, and, together with Chopin and Schumann, he firmly established the modern style of writing for the piano. His literary works, published in six volumes (Leipzig, 1880–83), are of permanent value, not only because of their critical acumen, but also because of their finished literary style, whether written in German or in French. Few great men have been more loyal to their friends and convictions than was Liszt, and still fewer have been so greatly beloved or so highly honored by the world. He died in the midst of a Wagner festival at Bayreuth, July 31, 1886.

The sum total of Liszt's compositions comprises 1233 numbers, of which 1122 have been printed. Of these 385 are original works, 264 arrangements of some of them for other instruments, 442 transcriptions and arrangements of works of other composers, and 31 revised editions of classical masterpieces. Foremost among Liszt's original works stand his 13 *Symphonic Poems*, and the *Faust* and *Dante* symphonies for orchestra; his great choral works *Graner Festmesse*, *Ungarische Krönungsmesse*, and the oratorios *Christus* and *Legende von der heiligen Elisabeth*. Of his piano works the *Harmonies poétiques et réligieuses*, *Années de Pélerinage*, *Légendes*, *Polonaises*, *Hungarian Rhapsodies*, and *Sonata* in B minor are in the repertory of every concert pianist, as well as his two concertos for piano and orchestra in E flat and A, and his *Totentanz* and *Wanderer Fantasie* (after Schubert), which to all intents and purposes are concertos for piano and orchestra. Besides these works, he wrote other masses, much sacred music, *a capella* choruses, organ pieces, and songs. A complete list of Liszt's published works was compiled by August Göllerich and appeared in the *Neue Zeitschrift für Musik* (1887–88). A complete thematic catalogue by the same author is in preparation.

LISZT, Franz von (1851–). A German authority on criminal law, born in Vienna, Austria. He studied at the universities of Vienna, Göttingen, and Heidelberg; lectured on penal law and civil processes at Graz in 1875–79; and became professor at Giessen in 1879, at Marburg in 1882, at Halle in 1889, and in 1899 at Berlin, where he was also director of the criminal-law seminar. In 1881 he founded, with A. Dochow, the *Zeitschrift für die gesamte Strafrechtswissenschaft*, and in 1888 he organized, with Professors Van Hamel and Prins, the Internationale Kriminalistische Vereinigung. Liszt became known as the greatest expert on criminal law in Germany and as a leading exponent of the scientific treatment of criminals. He was elected a member of the Reichstag in 1912. His publications include: *Meineid und falsches Zeugnis* (1876); *Die falsche Aussage vor Gericht* (1877); *Lehrbuch des österreichischen Pressrechts* (1878); *Das deutsche Reichspressrecht* (1880); *Lehrbuch des deutschen Strafrechts* (1881; 18th ed., 1911); *Der Zweckgedanke im Strafrecht* (1882); *Die Reform des juristischen Studiums in Preussen* (1886); *Der italienische Strafgesetzentwurf* (1888); *Die Deliktsobligationen im System des bürgerlichen Gesetzbuchs* (1898); *Das Völkerrecht, systematisch dargestellt* (1898; 9th ed., 1913); *Strafrechtliche Aufsätze und Vorträge* (2 vols., 1905).

LI TAI-PEH, lē tī-pĕ (c.700–763). One of the greatest of the Chinese poets, sometimes called Li Po. Born in a far western province, he became a member of a bacchanalian group of six young poets, wandered here and there, and, if we are to credit legend, spent several years in the mountains writing, singing, and drinking with his comrades. About 742 he went to the capital and became a client of the great minister Ho Shi-chang and later a court favorite of the Emperor Ming-hwang. But he was forced to flee from the palace because of intrigue, or possibly merely because of the dislike of the Emperor's favorite wife. According to Chinese story, he was drowned one night as he reached to kiss the moon's reflection at the side of his boat—plainly a materialization of one of his dainty conceits. More probably he died under the protection of Li Yang-pang after receiving Imperial forgiveness for his many attempts against the dynasty. One of the most popular of Chinese poets, Li Tai-peh is called the *prince of poetry*, the *great doctor*, and the *immortal who loved wine.* His poetical skill was versatile, and his subjects were varied. Much of his poetry has a touch of Anacreon, but in all there is a keen appreciation of the beauties of nature and most of all of the beautiful moon. Some selections are translated in Giles, *Chinese Literature*, pp. 152 et seq. (London, 1901), and in D'Hervey de Saint-Denys, *Poésies de l'époque des Thang*, pp. 1–72 (Paris, 1862).

LỊT'ANY (Lat. *litania*, from Gk. *λιτανεία*, *litaneia*, entreaty, from *λιταίνειν*, *litainein*, to entreat, from *λίτεσθαι*, *litesthai*, to pray, from *λιτή*, *litē*, prayer). In general, a solemn act of supplication to God. The first litanies were supplicatory processions, imitated from the pre-Christian religious processions. In all forms of litany the prayer alternates between the priest or other minister, who announces the object of each petition, and the congregation, who reply in a common supplicatory form, the most usual of which was the well-known "Kyrie eleison!" (Lord have mercy!). In one procession which Mabillon describes, this prayer, alternating with "Christe eleison," was repeated 300 times; and in the capitularies of Charlemagne it is ordered that the "Kyrie eleison" shall be sung by the men, the women answering "Christe eleison." From the fourth century downward, the use of litanies was general. The *Antiphonary* of St. Gregory contains several. In the Roman Catholic church three litanies are especially in use—the Litany of the Saints (which is the most ancient), the Litany of the Name of Jesus, and the Litany of Loreto. Of these, the first alone has a place in the public service books of the church, on the rogation days, in the ordination service, the service for the consecration of churches, the consecration of cemeteries, and many other offices. Although called Litany of the Saints, the opening and closing petitions, and indeed the greater part of the litany, consist of prayers addressed directly to God; and the prayers to the saints are not for their help, but for their intercession on behalf of the worshipers. The Litany of Jesus consists of a number of addresses to him under his various relations to men, in connection with the several details of his passion, and of adjurations of him through the memory of what he has done and suffered for the salvation of mankind. The date of this form of prayer is uncertain, but it is referred, with much probability, to the time of St. Bernardino of Siena, in the fifteenth century. The Litany of Loreto, so called because it has for ages been solemnly sung every Saturday in the chapel of the Holy House at Loreto, resembles both the above-named litanies in its opening addresses to the Holy Trinity, and in its closing petitions to the "Lamb of God, who taketh away the sins of the world"; but the main body of the petitions are addressed to the Virgin Mary under various titles—some taken from the Scriptures, some from the language of the Fathers, some from the mystic writers of the mediæval Church. The litany in the Prayer Book of the English church, although it partakes of ancient forms, contains no invocation of the Virgin or the saints. It is divided into four parts—invocations, deprecations, intercessions, and supplications—in which are preserved the old form of alternate prayer and response.

LITCH'FIELD. A borough and the county seat of Litchfield Co., Conn., 30 miles by rail northeast of Danbury, near Bantam Lake, the largest lake in the State, and on the New York, New Haven, and Hartford Railroad (Map: Connecticut, C 2). It has the Noyes Memorial Library, beautiful parks, and many places of historic and scenic interest. The borough is the centre of large dairying interests, and there are some manufactories, supplied with water power from the outlet of Bantam Lake. Situated 1100 feet above the sea, it is also a popular summer resort. Pop., 1900, 1120; 1910, 903.

Litchfield was settled in 1720, and several years later its present name was adopted. The borough was laid out in 1751 and incorporated in 1879. During the Revolution it was used for a time as a depot of supplies, and in 1776 the statue of George III, which on July 9 was torn down on Bowling Green, New York, was sent here and was melted and cast into bullets by the women of Litchfield. The first law school in the United States was founded here in 1784 by Judge Tapping Reeve. Many of the most eminent jurists and statesmen of the country, including five cabinet ministers—Calhoun, Woodbury, Mason, Clayton, and Hubbard—were trained here. In 1792 Miss Sarah Pierce opened in Litchfield one of the first institutions in America for the higher education of women. It was called the Litchfield Female Seminary, and flourished for about 40 years. Lyman Beecher was pastor of the First Congregational Church from 1810 to 1826, and it was in Litchfield that both Henry Ward Beecher and Harriet Beecher Stowe were born. Litchfield was also the birthplace of Ethan Allen, John Pierpont, and Charles Loring Brace; and the home for many generations of the distinguished Wolcott family. Consult: Kilbourne, *Sketches and Chronicles of the Town of Litchfield* (Hartford, 1859); the *Litchfield Book of Days* (Litchfield, 1900); and an article by Kilbourne, in the *Connecticut Quarterly*, vol. ii (Hartford, 1896).

LITCHFIELD. A city in Montgomery Co., Ill., 52 miles northeast of St. Louis, Mo., on the Wabash, the Cleveland, Cincinnati, Chicago, and St. Louis, the Illinois Central, the Chicago, Burlington, and Quincy, the Illinois Traction, and the Litchfield and Madison railroads (Map: Illinois, E 7). It has a Carnegie library, two hospitals, a fine Federal building, and parks. There is an abundance of coal, natural gas, and oil in the vicinity. Mining and manufacturing are the leading industries, the principal industrial establishments being manufactories of radiators, lamps, oil cans, windmills, and mine engines, flour mills, brick and tile plants, foundries, glassworks, and briquet works. Litchfield, incorporated in 1859, is governed by a mayor, elected every two years, and a unicameral council. Pop., 1900, 5918; 1910, 5971.

LITCHFIELD. A village and the county seat of Meeker Co., Minn., 65 miles west by north of Minneapolis, on the Great Northern Railroad (Map: Minnesota, C 5). It is of considerable importance as the commercial centre of a grain, dairy, and live-stock region, and has several grain elevators, a foundry, and machine shops, and manufactures dairy products, lumber, woolen goods, carriages and wagons, etc. The city contains a Carnegie library and owns its water works, electric-light and heating plants. Pop., 1900, 2280; 1910, 2333.

LITCHI, or **LEECHEE,** lē'chē' (Neo-Lat., from Chin. *lichi*), *Litchi chinensis* or *Nephelium litchi*. A large evergreen tree of the family Sapindaceæ, native of China and the Malay Peninsula, and extensively grown in many tropical countries. It is highly prized for its fruit, which is said to be one of the most delicious known. It is cultivated in the West Indies, and attempts have been made to introduce the trees in Florida, but with little success, as the tree is very susceptible to injury by cold and thrives only in the extreme southern part of the State. It is reported as tolerant of the conditions found in parts of southern California. The fruit is a nut an inch or more in diameter, which consists of a thin, rough, brittle shell within which is a sweet pulp surrounding a hard seed. The pulp separates readily from the seed and is eaten fresh, dried, or as a sort of preserve. In the dried state the nuts keep a long time, and it is mostly in this form that they are found in commerce. Chinese and Japanese stores usually keep them in stock. The fruit is principally used as a confection, sugar being one of the chief constituents of the pulp. Fruits of species of *Nephelium* resemble the litchi and are used in a similar manner. The principal ones are the rambutan (*Nephelium lappaceum*), which has a bright-red fruit covered with soft spines; and the longan (*Nephelium longana*), a tree of moderate size and fine appearance, which is readily cultivated, the fruit of which is smaller and inferior to the litchi. Some botanists combine the two genera under the name *Nephelium*.

LITCHI.

LIT DE JUSTICE, lē dĕ zhu̧s′tēs′. See Bed of Justice.

LITER, lē′tĕr. A measure of volume. See Metric System.

LIT′ERARY PROPERTY. Property in ideas, expressed in written or printed language. Literary property, as defined by Drone, is "the exclusive right of the owner to possess, use, and dispose of intellectual productions," and copyright is "the exclusive right of the owner to multiply and dispose of copies of an intellectual production." The English statute (5 and 6 Vict.) defines copyright to mean "the sole and exclusive liberty of printing or of otherwise multiplying copies of any subject to which the word is herein applied." The American statute (U. S. Rev. Stat., sec. 4952) speaks of copyright in a book as "the sole liberty of printing, reprinting, publishing, . . . and vending the same."

Property in an intellectual production, comprising the exclusive right of multiplying for sale copies of literary or of art productions, is of comparatively recent date. Whatever theories might have been held during the time of the Roman state in regard to the rightfulness of the claim of the author to enjoy the usufruct of all the copies of his production, the manifest impossibility of securing, under the conditions then obtaining, by any process of law or any application of the authority of the state, the control of such usufruct, prevented the lawyers of the time from giving any serious attention to the question. In these earlier discussions as to the nature of property in ideas, special attention was given to the question whether such property should take precedence over that in the material which happened to have been utilized for the expression of the ideas. The jurist Tribonian, who was selected by Justinian to supervise the preparation of the Justinian Code, followed an opinion of Gaius (given about 150 A.D.) which, having reference to the ownership of a certain tablet upon which a picture had been painted, gave the tablet to the artist. This decision contains an unmistakable recognition of immaterial property, not, to be sure, in the sense of a right to exclusive reproduction, but in the particular application that, while material property depends upon the substance, immaterial property, i.e., property in ideas, depends upon the form.

Apart from the difficulty of preventing the appropriation of their literary productions, the feeling on the part of the Roman writers that authorship was not in itself a worthy vocation, but was to be considered simply as a pastime, unquestionably stood in the way of arrangements under which authors secured compensation for their productions, and doubtless postponed for a considerable period the recognition by the publishers and by the reading public of any property rights in literature. It appears from the letters of Cicero, Horace, Martial, and others that they made a profit from the sale of their writings.

For the centuries following the destruction of the Roman Empire, during which literary undertakings were confined almost entirely to the monasteries, the Roman usage, under which authors could dispose of their works to booksellers and the latter could be secure of some commercial control of the property purchased, was entirely forgotten. No restrictions were placed on the duplication of works of literature. The statutes of the University of Paris, issued in 1223, provided that the booksellers of the university were to produce duplicate copies of all the texts authorized for the use of the university. Throughout the Middle Ages, whatever immaterial property in realms of science or of art obtained recognition and protection was held in ownership, not by individuals, but by churches, monasteries, or universities. The writers of the Middle Ages were satisfied when they could succeed under any conditions in getting their productions before the public.

The printing press brought with it the possibility of a compensation for literary labor. Very speedily, however, the unrestricted rivalry of printers brought into existence competing and unauthorized editions, which diminished the prospects of profit, or entailed loss, for the authors, editors, and printers of the original issue, and thus discouraged further undertakings. As there was no general enactment under which the difficulty could be met, protection for the authors and their representatives was sought through special privileges obtained for separate works as issued. The earliest privilege of the kind was that conceded by the Republic of Venice in January, 1491, to the jurist Peter of Ravenna, securing to him and to the publishers selected by him the exclusive right for the printing and sale of his work *Phœnix*. No term of years was named in this privilege. The larger number of the earlier Italian enactments in regard to literature were framed not so much with reference to the protection of authors as for the purpose of inducing printers (acting also as publishers) to undertake certain literary enterprises which were believed to be important to the community. The Republic of Venice, the dukes of Florence, and Leo X and other popes conceded at different times to certain printers the exclusive privilege of printing for specific terms (rarely exceeding 14 years) editions of classic authors; not so much to secure profits for the printers, but rather to encourage, for the benefit of the community, literary ventures on the part of the editors and printers.

In France, from the reign of Louis XII to the beginning of the sixteenth century, it became the usage for the publisher, before undertaking the publication of a work, to obtain from the King an authorization or letters patent, the term of which varied according to the nature of the work and also to the mood of the monarch or of the advising ministers. The status of literary property was further recognized and defined by the so-called *Ordonnances des Moulins* of Charles IX in 1566 and the letters patent of Henry III in 1576, but the general method under which copyrights were granted and defended remained practically the same. These royal letters were for the most part in the earlier years, as has been the case in Italy, issued for the protection of special editions of the classics. They were concerned, therefore, not with the protection of original ownership, but with the encouragement of investments on the part of the printer publishers in scholarly undertakings. In so far as these editions included original work (in connection with the revision or annotation of the texts), this work had been paid for by the publishers, who stood, therefore, in the place of the writers. The National Assembly in 1789 abolished all royal privileges then in force for the protection of works of literature. In July, 1793, the first general Copyright Act was passed. This gave protection to the author during his life and to his heirs and assigns for 10 years thereafter. The Imperial Act of 1810 extended the term in behalf of the author and his widow for life, and of their children for 20 years. The Law of March 28, 1852, prohibited the production in France of unauthorized editions of foreign works. The Law of April 8, 1854, increased the term in behalf of the children to 30 years, while the Act of July 14, 1866, increased the period of protection in behalf of heirs to 50 years after the death of the author. The decree of the 9th of December, 1857, declared the copyright legislation of France applicable to the French colonies named, and subsequent copyright legislation was made applicable in all the colonies by the decree of Oct. 29, 1887. The provisions of these acts apply equally to foreigners and to Frenchmen, and no restriction is made as to the author's residence at the time the copyright is taken out. In case the work be first published abroad, copyright in France may be secured subsequently by the deposit of two copies with the Minister of the Interior or with the secretary of the prefecture in the departments. The most important modifications of this act have been in connection with the Convention of Bern of 1886–87 and the convention with the United States in 1891, reference to which will be made later.

The earliest German privilege of which there is trustworthy record was issued in 1501 by the Aulic Council to an association entitled the *Sodalitas Rhenana Celtica*, for the publication of an edition of the dramas of Hroswitha of Gandersheim, which had been prepared for the press by Konrad Celtes. This Hroswitha privilege, while later than the early Venice privileges, antedates by two years the first instance in France, and by 17 years the first in England. After 1501 there is a long series of Imperial privileges issued directly by the Imperial Chancellor in the name of the Emperor. In 1512 an Imperial privilege was issued to the historiographer John Stadius for all that he should print, the first European privilege which was made to cover more than a single work or which undertook to protect books not yet published. An Imperial patent of 1685 uses the terms (as if in antithesis to each other) "A privileged book" and "A book purchased from its author." Later we find references to "privileged" and "non-privileged" books. Pütter (who may be called the father of the modern theory of property in literary productions), writing in 1774, uses for the unprivileged books the term *eigenthümlich* (individual) and for the privileged the term *nichteigenthümlich* (nonindividual). Literary piracy in Germany began almost at once with the invention of printing. Before manuscript copies had been replaced by printed books the possession of a manuscript was held to carry with it the right to make copies of the same *ad libitum*. As a natural consequence of this practice the possession of a printed copy of a work was for a considerable time also believed to carry with it the right to make and dispose of further printed copies, and the first upholders of an author's copyright found themselves obliged to contend against the claim of ancient precedent. Early in the history of the German book trade there arose, however, a practice among the leading publishers of respecting each other's undertakings, irrespective of any privileges or of other legal protection given to the works in question. To this practice there were, of course, numerous exceptions, but it exercised nevertheless, during the period previous to the existence of a national copyright system, an important influence in indicating the tendency of the book trade and that of the reading public to a recognition of and a respect for literary property. It also placed the publishers in a better position to make satisfactory payments to the authors or editors employed by them. The many important publications of Koberger of Nuremberg, whose business activity dated from 1473, were issued entirely without privilege, and with a few exceptions were not interfered with by rival publishers. In 1532 the magistrates of Nuremberg, acting on behalf of the widow of Albert Dürer, enjoined Hans Güldemund from reëngraving the *Triumphwagen* and selling impressions of his plate. In the same year these magistrates cautioned all the booksellers of Nuremberg against keeping in stock or selling any copies of a certain unauthorized edition of Dürer's *Instruction in Perspective*. Under the order of the magistrates of the city of Basel, issued in

October, 1531, printers of books in that city were enjoined for a period of three years, under the penalty of 100 gulden, from reprinting or pirating the books of one another. Until nearly the end of the eighteenth century the protection of literary property in Germany depended upon a system of privileges, Imperial or local, but these privileges were for the most part concerned simply with the property interests of the publishers and printers, but a small proportion of them having to do with modern books or with the rights of living authors. Such privileges covered at the outset three classes of literary undertakings: first, official publications—a term including in the earlier times the service books of the Church and school textbooks, as well as the authorized text of government edicts, laws, and enactments; second, editions of works taken from the body of the world's literature (*literarisches Gemeingut*), i.e., the first printing (*Vordruck*) of the same; and third, new books presenting the first consideration of a specific subject, more particularly of a scientific, technical, or practical nature. For this last class of undertaking the recipient of the privilege claimed a control not only of the specific book which he had produced or of which he was the owner, but the monopoly for the time being, within the district covered by the privilege, of the subject considered in such book. The writer who had produced a book on "The Use of Herbs," or the publisher who had employed a writer to prepare such a book (the subject not having been treated before or at least not recently), would consider himself aggrieved and would contend that his rights had been infringed if within the same territory the publication of another book on herbs should be permitted. If the privilege covered an edition of a Latin author, the holder believed himself authorized to prevent the publication, within the territory covered by his privilege, of any other edition of the same author, even though such competing edition might, in respect to the revision of the text and to the editorial work in the notes and commentaries, be entirely distinct from his own. Local privileges of this kind, which undertook to give to the possessor an exclusive control, during a certain term, over a specified classic text, were, of course, practically identical with the trade monopolies, also characteristic of the age, which were conceded for the sale, within specific territories, of articles such as salt or wool.

In 1794 legislation was inaugurated in the Prussian Parliament which was accepted by the other states of Germany (excepting Württemberg and Mecklenburg), under which all German authors and foreign authors whose works were represented by publishers taking part in the book fairs in Frankfort and Leipzig were to be protected throughout the states of Germany against unauthorized reprints. This Berlin enactment may be credited as the first step towards a practical recognition of international copyright. It proved, however, difficult, at least until after 1815, to enforce the provisions of these interstate enactments.

The first copyright privilege in England bears date 1518 and was issued to Richard Pynson, King's printer, the successor, second in line, to Caxton. The privilege gives a monopoly for the term of two years. The date is 15 years later than that of the first privilege issued in France. In 1530 a privilege of seven years was granted to an author in consideration of the value of his work. This is cited by Scrutton as the first record of an English copyright issued to an author. Royal privileges continued to be issued during the sixteenth century, while, after 1556, the entries in the registers of the Stationers' Company are made evidence of the exclusive rights to the persons named for printing the books specified. The Stationers' Company, in giving title to property in a "copy" or literary production, acted as the representative of the authority of the crown, an authority secured to it through royal charter. The control of the work of the Stationers was, in 1637, placed in the hands of the Star Chamber. The replacing in 1640 of the absolutism of the Star Chamber by the absolutism of the Long Parliament made no change in the completeness of the authority left with the Stationers' Company. The Parliamentary Ordinances of 1641, in prohibiting printing or importing without the consent of the owner of "copies" of books, constituted a clear statutory recognition of property in "copy," a recognition evidently based upon its existence under the common law. The Act of 1643 for "redressing disorders in printing," and the Licensing Act of 1662, while having for their main purpose the control of literature in connection with its influence on politics, continued to affirm or to imply the existence of property in the "copy" of books. The English authorities on the subject, Maugham, Coppinger, Scrutton, and others, and the American Drone, are at one in the opinion that at the close of the seventeenth century it was the general understanding in England that authors possessed in their productions a perpetual right of property and that this right could be assigned. This understanding, upon which were based parliamentary acts for regulation and for license, and in accord with which were carried on important and continued business undertakings, marked a development in the conception of literary property which had not then been reached elsewhere. The Act of Queen Anne, which went into effect in 1710, under which a statutory protection for a term of 14 years was given to the author of a literary production (with provision that if he were alive at the expiration of that period his copyright could be extended 14 years), brought to a close, for Great Britain, the period of common-law copyright. This result was probably not intended by the legislators who framed the act and was certainly not anticipated by the publishers at whose instance the matter had been taken up and who were simply applying for a more specific and more effective protection, covering such term as Parliament might see fit to grant, for the property in their "copies," of the existence of which property there had as yet been no question. It was, in fact, not until 1769 that any serious contention was raised against the continued validity of copyright at common law. In that year the common-law right was maintained in the decision rendered in the famous case of Millar *v.* Taylor, a decision rendered the more noteworthy because it was concurred in by Lord Mansfield, the greatest authority on the subject of copyright whom Europe had thus far known. In 1774, in the case of Donaldson *v.* Becket, the issue was raised for the second time, the property involved being the same in each suit, the copyright of Thomson's *Seasons*. In this case the House of Lords reversed its previous decision. Its conclusions were in substance:

first, that an author had a common-law right to his production before publication (10 judges in the affirmative and one dissenting); second, that, after publication, such common-law right still rested in the author (eight judges in the affirmative and three in the negative); third, that, under the Statute of 1710, the author had lost his right of action at common law and retained protection for his copyright only during the term prescribed by the statute (six judges in the affirmative and five in the negative); fourth, that the right at common law possessed by the author and his assigns prior to 1710 had been a right in perpetuity (seven judges in the affirmative, four in the negative). In each of these votes, including that of the vital issue of the effect upon the common-law right of the Statute of 1710, Lord Mansfield was recorded in favor of the continued right of the author at common law, and of the perpetuity of copyright, irrespective of the effect of this statute. The effect of this decision was, as said, to replace what may be called the common-law period of a copyright in England by a copyright protection limited to the terms of the successive statutes.

The copyright law now in force in Great Britain is in substance that of 5 and 6 Vict., c. 45, enacted in 1842, with amendment of 1862 for paintings and photographs. Exclusive right to perform dramatic pieces is given by the Statute of 1833. Sculpture is provided for under the Act of 1813.

The copyright act was the result of a parliamentary movement initiated by Sergeant Talfourd, conducted later by Lord Mahon. Under Talfourd's Bill of 1841 it was proposed to extend the term of copyright to a period of 60 years from the death of the author. The principal opponent of this longer term was Macaulay, at that time a member of the House. Macaulay's views prevailed, and the Talfourd Bill was defeated. The term finally arrived at was that suggested by Macaulay, and it was also at his instance that the provision was added against a possible suppression of books by the owners of the copyright.

In the United States the first Act in regard to copyright was passed in Connecticut in January, 1783. This was followed in the same year by the acts of Massachusetts, Maryland, New Jersey, New Hampshire, and Rhode Island, and before May, 1786, all of the other original States except Delaware had passed similar acts. These acts were due more particularly to the efforts of Noah Webster and their first service was the protection of his famous *Speller*. Webster journeyed from State capital to State capital to urge upon governors and legislatures the immediate necessity of copyright laws, and his persistent efforts were crowned with success. The necessity for State laws on the subject was, however, obviated by the United States Statute of 1790. Previous to the adoption, in 1787, of the Federal Constitution, a general copyright law was not within the province of the central government, and in order to encourage the States in the framing of copyright legislation a resolution, proposed by Madison, was adopted in Congress in May, 1783, recommending to the States the adoption of laws securing copyright for a term of not less than 14 years, with right of renewal for 14 years more. Certain of the State acts granted longer terms. The Act of 1790, however, provided for the double term suggested by Madison. The Act of 1831 extended the 14 years to 28, with the privilege to the author, his widow, or the children, of renewal for 14 years more. The statute law relating to copyright is to be found in U. S. Rev. Stat., Tit. 60, c. 3 (1874), with later amendments, of which those of March, 1891, introduced international provisions. Under the interpretation of the United States courts, copyright in published works exists only by virtue of the statute, while in the works that have not been published, such as compositions prepared for dramatic representation, the copyright obtains through the common law. The United States decision which still serves as a precedent on the point of statutory limitation of copyright is that of the United States Supreme Court in 1834 in the case of Wheaton *v.* Peters. This decision involved the purport of the United States Law of 1790 and the determination of the same question that had been decided by the House of Lords in 1774, viz., whether copyright in a published work existed by the common law, and if so, whether it had been taken away by statute. The court held that the law had been settled in England, the Act of 8 Anne, c. 21, having taken away any right previously existing at common law; and that the Copyright Statute of 1790 did not affirm a right already in existence, but created one; and finally, that there was no common law of the United States in force. Justices Thompson and Baldwin, in opposing the conclusions of the four justices concurring in this decision, took the ground that the common law of England *did* prevail in the United States, that copyright at common law had been fully recognized, and that even if it were admitted that such copyright had been abrogated in England by the statute of Anne, such statute had, of course, no effect either in the colonies or in the United States. In 1880, in the case of Putnam *v.* Pollard, it was claimed by the plaintiff that the decision in Wheaton *v.* Peters could, in any case, only make a precedent for Pennsylvania; that the English common law obtained in the State of New York, and could not have been affected by the statute of Anne; but the New York Supreme Court decided that Wheaton *v.* Peters constituted a valid precedent.

International Copyright. The first country to take action in regard to international copyright was Prussia, which in 1836 passed an Act conceding the protection of the Prussian statute to the writers of every country which should grant reciprocity. In 1837 a copyright convention was concluded between the different members of the German Confederation. This was confirmed in 1870 between the states which were then brought together in the newly constituted German Empire. In 1838 an Act was passed in England under which the crown might, by order in council, grant the privilege of copyright to authors of books first published in any foreign country, to be named in such order, provided always that "due protection had been secured by the foreign Powers so named for the benefit of parties interested in works first published in British dominions." Under this act Great Britain entered into copyright conventions with Saxony, 1846; Hanover, 1847; France, 1851; Prussia, 1855; Belgium, 1855; Spain, 1857; Sardinia, 1862; and Italy, 1867. Interstate conventions were also arrived at during the same period between most of the literature-producing states of Europe, the noteworthy exceptions being Belgium (which profited largely through the unauthorized reprinting of books originating in

France), Holland, and Hungary. In 1887, under the Bern Convention, the states of Europe and certain states outside of Europe united in a copyright system which protected, throughout the territory of the states that were party to the convention, the works produced in each of these states. The states taking part in this international union comprised at the outset Great Britain (including the British colonies), Germany, France, Belgium, Spain, Italy, Switzerland, Haiti, and Tunis. Since 1887 the following states have come into the union: Luxembourg, Monaco, Montenegro, Norway, Japan, and Denmark. The most noteworthy exceptions, among the literature-producing countries, to membership in the convention are Holland, Russia, Austria-Hungary, and the United States. In 1896 a diplomatic conference met in Paris to discuss a revision of the Bern Convention, and drew up a modification known as the Act of the 4th of May, 1896. The association maintains a permanent bureau at Bern, and under its initiative conferences have been held at brief intervals through the action of which the provisions of the union have been perfected. In 1901 the International Publishers' Association established at Bern a permanent bureau whose work is carried on in coöperation with that of the Bern Convention.

In the United States efforts to secure international copyright relations extended over a period of more than 50 years. In 1837 Henry Clay presented to Congress a petition of British authors asking for American copyright. In 1843 George P. Putnam presented to Congress a memorial drafted by himself, and signed by 97 publishers and printers, in which it was stated that "the absence of an international copyright was alike injurious to the business of publishing, and to the best interests of the people at large." In 1841 was organized the first International Copyright Association, of which George P. Putnam was the secretary. Between that date and 1891, 14 copyright measures were introduced into Congress. In 1887 the American Copyright League, composed in the main of the authors of the country, appointed an executive committee to take action to further the measures then pending in behalf of international copyright. Of this committee Mr. R. U. Johnson was, during the greater part of its activity, the secretary. In the same month was organized the American Publishers' Copyright League, with W. H. Appleton as president and G. H. Putnam as secretary. In 1891 was finally secured the enactment of the bill, drafted under the direction of the Publishers' League, which made such modifications in the existing statute as to concede copyright in the United States to the authors of foreign states in which American authors were placed in a position to secure similar copyright protection. The most important limitations in the copyright as granted in the Act of 1891 were the requirements that the foreign book to secure protection of the American statute must be produced from type set within the limits of the United States, and that two copies of the book so produced must be deposited in the Library of Congress not later than the date of publication of the work in this or any foreign country. The requirement that the work of an American author should, in order to secure copyright in this country, be manufactured in this country was new. While, through the passage of the Act of 1891, the United States had finally put itself on record in company with the other civilized states of the world in recognizing the property rights of literary producers, it was not in a position to accept membership in the Convention of Bern. The requirement that the copyrighted book must be manufactured in this country, coupled with the requirement for simultaneous publication, made conditions which were incompatible with the regulations accepted by the Bern association. This additional measure for securing American copyright for aliens (and, under reciprocity, foreign copyright for Americans), a measure which is the result of 53 years of effort on the part of individual workers and of successive copyright leagues, brings this country to the point reached by France in 1810 and by Great Britain and the states of Germany in 1836–37. Imperfect as the Act may be as judged by the present standards of international copyright legislation, it not only marks a great advance in the development of public and legislative opinion in the United States, but has resulted in substantial gains for the authors of America, for the authors of Great Britain, and for the American book-buying public.

The results of this Act have not proved wholly satisfactory. As far as it concerned authors whose books originated in a language other than English, the Act has produced no real benefit. The authors of France, Germany, and Italy—states which are in direct intellectual relations with the United States, and whose governments have accorded to American writers the same copyright protection as it secured for their own authors—secure copyright in form but not in fact. The difficulty of inducing American publishers to make investments in American editions of continental books is not obviated because of the fact that the American law does not place the publishers in a position to protect themselves against unauthorized competing editions. Since the copyright secured for a translation of a book not copyrighted in the United States in the original text would cover only the particular version, a piratical competitor might produce, in case the work should prove a success, another version, reaping the advantage of the literary judgment and of the advertising contributed by the original and authorized publisher. As a result, the production of American editions of continental works has, since the Act of 1891, been inconsiderable. Foreign authors secured but trifling returns from American publication from the simple fact that they secured very few readers, and American readers failed to obtain the advantage of a knowledge of current continental literature, the reading of which would have widened their general cultivation and have helped to lessen international prejudice. The law has thus deprived American publishers, and all who have a business interest with these publishers in the trade of book manufacturing, of the opportunity of making legitimate profit from the production of American editions of the works of continental authors. The law has also proved defective in the provisions relating to the protection of works of art, provisions which were framed some time in advance of the development of important methods of art production, and in its failure to extend the term of copyright with a view to securing for the producers of intellectual property the control of their productions during their own lifetime, and of preserving for their heirs the enjoyment of the results of these productions during a reasonable term after the death of the producer. The United States should not have been satisfied with according to literary producers a smaller term of protection than is considered advisable by any other civilized state excepting Greece.

The diverse theories in regard to literary property which, in the shaping of the copyright legislation of the world, have come into discussion may be briefly summarized as follows: First, property in an intellectual conception or creation is analogous to property in a material creation, and implies as comprehensive and unlimited a control for the production as that conceded by the community to other classes of productions; second, intellectual property depends upon an individual agreement or convention, to which each person enjoying the use of a copy of a literary or artistic production makes himself a party; third, property in an intellectual production depends upon the natural or personal rights of the author, who, through unauthorized appropriations, may suffer an injury or tort; fourth, property in an intellectual production is the creation of statute, and is subject to limits depending, not upon the natural rights of the producer, but upon the convenience or advantage of the community.

Of these several theories or conceptions, it is the fourth which represents in substance the survival of discussions of two centuries, and which has formed the basis of the copyright legislation of both Europe and America.

For further particulars as to the copyright legislation now in force in the United States and elsewhere, see Copyright and United States Copyright Act.

LITERATURE. See Criticism.

LITH'ARGE, formerly Lithargie; Lithargy. The yellow or red oxide of lead (PbO). It is formed by intensely igniting lead or lead compounds in the air. It melts at a red heat and is volatile at white heat. It may be formed by heating metallic lead, molten, in contact with the air for a long time. When the temperature is insufficient to melt the oxide, the latter is of a dull-yellow color, sometimes called massicot, but at melting temperature takes a brighter and redder color. In the compound the lead is bivalent. Cooling the molten oxide allows the formation of a mass of reddish-yellow, six-sided plates, semitransparent. It is sparingly soluble in water, has an alkaline reaction, and readily forms salts with acids. It may be reduced to metal by heating in hydrogen or carbon monoxide, or on heating in the inner blowpipe flame (reducing), or by heating with carbon. It dissolves in sugar solution. It is much used in assaying as a flux and as a gatherer for silver and gold. It is used in the composition of flint glass and in glazing earthenware. It is used also in the manufacture of varnishes and drying oils. See Lead.

LITHERLAND, lith'ẽr-land. A manufacturing town in Lancashire, England, 4½ miles north of Liverpool. Pop., 1901, 10,600; 1911, 14,795.

LITHIA EMERALD. See Hiddenite.

LITH'IC-ACID DIATH'ESIS (from Gk. λιθικός, *lithikos*, relating to stone, from λίθος, *lithos*, stone); Uric Acid Diathesis: Lithæmia; Lithuria. An excessive production of lithic (or uric) acid and its salts in the body, coincidently with which there is lessened alkalinity of the blood, rendering that fluid less able to hold the acid and its salts in solution. The latter thus become deposited in various tissues, particularly in the joints and the spleen. Sufferers from this condition are said to have the lithic-acid diathesis. Their urine is of a dark-golden color and is more acid, of higher specific gravity, and less abundant than the urine of health. It deposits urates on cooling, and it may contain albumen or traces of sugar. The output of uric acid is low at times, but the urine may be loaded with it at other times.

There is a motley group of symptoms (one writer has enumerated 39) indicative of the lithæmic state. Persons who have lived not wisely but too well, who have eaten and drunk largely, and persons who lead sedentary lives, may manifest it. Cases are seen in members of gouty families, who may never themselves have suffered from that disease. In such a family the daughters often escape, while one son may have lithæmic attacks of great severity, even though he may lead a temperate life and try in every way to avoid the conditions favoring the disorder. Cutaneous eruptions, such as eczema, are frequently associated with this diathesis; as are also disorders of the stomach and intestines, such as furred tongue, foul breath, and constipation. It may be accompanied by symptoms of a torpid liver. There may be a swelling of the parotid gland, simulating mumps.

Disorders of the circulatory system are frequently associated. The blood tension is persistently high, the walls of the blood vessels become stiff, and heart and kidney changes gradually develop, when dropsy may supervene. It is not unlikely that the lithæmic state may hasten the development of aneurism or apoplexy; for the nutritional disorder with which an excess of uric acid is associated induces in time increased tension in the blood vessels, hardening of the arteries, chronic kidney disease, and changes in the muscular tissue of the heart.

Among nervous manifestations headache is frequent. Neuralgias, particularly sciatica, are not uncommon. There may be hot or itching feet at night. This symptom is as old as Plutarch, who observed it and called it "the lisping of the gout." But, as a rule, the peripheral circulation is sluggish and the feet cold. Cramps in the legs and hot and itching eyeballs may be signs.

Chronic bronchitis is frequent in such cases, as are also certain affections of the eye, such as iritis, retinitis, and glaucoma.

The treatment is hygienic, dietetic, and medicinal. Treatment is begun by a system of hot baths, saline cathartics and diuretics, until all the eliminating channels are functionating normally. The lithæmic subject should live temperately, abstain from alcohol, and eat moderately. He should live in the open air, exercise vigorously, and keep regular hours. The skin should be kept active by cold baths with friction for the robust, and by warm evening baths for the debilitated. The dress should be warm, extremes of temperature should be avoided, and care should be taken not to have the skin suddenly chilled. The appetite should be kept within reasonable bounds, meals should be at stated intervals, and food should be well chewed and eaten slowly. In the matter of food, quantity is a factor of more importance than quality. Meats, tea, coffee, alcohol, especially malt liquors, and tobacco should be rigorously restricted. Each individual case should receive separate consideration from the physician. Nowhere, perhaps, is it more necessary than in lithæmia to consider the man as well as the ailment, and very often more the man than the ailment. This is especially so when we consider the possible sequelæ of this state. Among medicines, mild alkaline mineral waters, wine of colchicum, citrate of potash, sodium salicylate, iodide of potash, guaiacum, quinine, piperazin, and the bitter tonics are employed. For external application, warm fomentations, ichthyol, and steaming are appropriate. Whenever the blood becomes increasingly alkaline, some of the accumulated acid is washed out of the spleen and the joints, and, before it is eliminated from the system, attacks the nerve centres and the blood vessels. The result is headache and depression of spirits. Acids relieve the symptoms, but cause further accumulation in the joints and spleen, with later serious results. Consult: Alexander Haig, *Uric Acid as a Factor in the Causation of Disease* (London, 1908); Miles, *Muscle, Brain and Diet* (ib., 1900); Brunton, *Disorders of Assimilation, Digestion, etc.* (ib., 1901). See GOUT; RHEUMATISM.

LITH'IUM (Neo-Lat., from Gk. λίθος, stone). A metallic chemical element, whose oxide was discovered in 1817 by Arfvedson. The metal itself was first obtained by Brandes in 1822, and a quarter of a century later Bunsen and Matthiessen invented the process now used in making it. (See below.) Lithium is distributed in nature widely, but in very small quantities, the only minerals containing considerable amounts of it being the rare minerals spodumene, lepidolite, petalite, triphylene, and amblygonite. It is also found in certain mineral waters and in the leaves of certain plants. Finally, it occurs in meteorites, and its presence has been detected in the sun. In order to extract the lithium from a given mineral (say, lepidolite), the latter is fused, so as to render it capable of being decomposed by strong hydrochloric acid; the acid is caused to act on the mineral for several hours, nitric acid is added to the resulting solution, then the solution is diluted and neutralized with sodium carbonate. On filtering and concentrating, the solution is precipitated with an excess of sodium carbonate. The resulting lithium carbonate may then be transformed into other lithium compounds, among which the chloride may be used to obtain metallic lithium, by means of a strong voltaic current passed through the fused salt. In 1904, 577 short tons of lithium minerals, valued at $5155, were produced in the United States, and the importation of such minerals had practically ceased.

The element lithium (symbol, Li; atomic weight, 6.94) is the lightest metal known, its specific gravity being about 0.59. It is white, it can be pressed into wire, and it can be welded at ordinary temperatures. If exposed to the air, it soon becomes covered with a yellowish-white film of oxide. Like sodium and potassium, with which it is classed as one of the "alkali metals," it decomposes water with great readiness. It is, on the other hand, less volatile than sodium or potassium and does not distil at a red heat. Its melting point is 186° C. (about 367° F.). Again, like sodium and potassium, it dissolves in liquid ammonia, the solution having a blue color. With ammonia it also forms a brownish-red solid having the composition $LiNH_3$.

Lithium Compounds. Among these deserve mention the oxide, the carbonate, the citrate, and the salicylate. The *oxide*, Li_2O, may be prepared by heating the carbonate with charcoal; with water it forms the hydroxide, LiOH, which may, by crystallization from aqueous alcohol, be obtained as $LiOH + H_2O$; the hydroxide may also be prepared by the action of lime on lithium carbonate. The *carbonate* of lithium, Li_2CO_3, is a light, white powder, sparingly soluble in water, but insoluble in alcohol. The *citrate* of lithium, $Li_3C_6H_5O_7$, is a white powder readily soluble in water; it may be prepared by the action of citric acid on lithium carbonate; "effervescent lithium citrate" may be prepared by mixing sugar with citric acid, drying the mixture, and adding to it sufficient quantities of sodium bicarbonate and lithium carbonate. The *salicylate* of lithium, $LiC_7H_5O_3$, is a white powder readily soluble in water and in alcohol; it may be prepared by heating lithium carbonate with salicylic acid and water, until effervescence ceases. A number of lithium salts are used in gout, in uric-acid gravel, and calculus, owing to their capacity for causing sodium urate to dissolve in water. The carbonate, in the form of a lotion, is used to alleviate the pain of gouty inflammation and to heal gouty ulcers. The presence of lithium compounds in a given substance can be readily recognized by introducing a small amount of the substance into a colorless flame (like that of the Bunsen burner), to which they impart a characteristic red coloration.

LITHOD'OMUS, LITHOPHAGUS. See MUSSEL.

LITHOFRACTEUR, lĭth'ō-frăk-tẽr'. See EXPLOSIVES.

LITH'OGEN'ESIS. The branch of geologic science which deals with the origin of rocks. As to the nature of the rock masses which constituted the crust of the earth upon its primary cooling, little is known, nor is it certain that they are represented in any of the formations of the present day. From a study of the rock-forming processes now going on, and of the character of those masses that are exposed at the earth's surface, geologists have grouped all rocks upon a genetic basis, into three great classes or divisions. 1. The metamorphic rocks include those that have been profoundly changed from their original condition. The oldest rocks of which we have knowledge—the gneisses and crystalline schists—are members of this class; they are characterized by a banded or foliated structure and may have originated from either sedimentary or igneous rocks by the effects of heat and pressure. 2. The igneous rocks comprise those which have cooled from a molten condition, such as lavas and granites. They have a massive structure and a glassy or crystalline texture. 3. The sedimentary rocks include those which have been derived from the igneous or metamorphic rocks by disintegration and decay, and which have been laid down on water or land. The water-deposited or aqueous rocks are the most important of this class; they are largely composed of fragmentary materials arranged into layers or strata and hence are known also as sedimentary rocks. See AQUEOUS ROCKS; ROCK.

LITH'OGRAPH'IC STONE (from Gk. λίθος, *lithos*, stone + γράφειν, *graphein*, to write). An even-grained, compact limestone, generally of a gray, drab, or yellowish color, that finds extensive use in lithography.

LITHOG'RAPHY. Properly speaking, the art of writing, drawing, or engraving on stone of a particular kind, or on metals endowed with similar qualities; in a more general sense, the art of chemical or surface printing from stone or metal, by means of which drawings or writing traced with fatty ink are multiplied, in contradistinction to letterpress or relief, and copperplate or intaglio printing.

This art or process is based purely upon the principle of chemical affinity of fatty or resinous matter for substances of the same nature and their repugnance for water. The stone or metal used is, by reason of its porosity, capable of receiving and retaining water to the evaporating point, as well as fatty or resinous matter, to such an extent that to remove it mechanical means or powerful chemical agents are necessary.

Processes and Materials. When a drawing is made on stone or metal with either lithographic crayon or ink, and all other parts of the surface are moistened with water, both the fatty substance and the moisture will penetrate the porous surface. A roller covered with fatty or resinous printing ink passed over this stone or metal will cause the ink to adhere to the fatty or resinous parts constituting the design and will be repelled by the moist parts; in consequence, the former only will appear in an impression.

The stone used in lithography is a variety of calcium carbonate of porous texture, known as "lithographic stone." The best variety is found at Solenhofen, Bavaria, and almost the entire industry receives its supply from that source. Stone of an inferior quality is quarried in England, France, Italy, Prussia, and Russia, and in later years in Canada and some of the Western States. Lithographic stone varies in color from a blue gray to a yellowish gray, the best quality being found among the light-gray and sometimes among the dark-yellow varieties. The dark-blue-gray or French stone is very fine in texture, but its color does not contrast sufficiently with that of the design to enable the artist or transferer to judge his work as well as on the light-gray stone. It is sawn at the quarries into slabs from 3 to 4 inches in thickness, varying in size from 6 × 8 inches to 44 × 64 inches, and sold at prices ranging from 1½ cents to 30 cents per pound, according to size and quality. The larger sizes are extremely scarce when without flaws, such as open veins, streaks of glass, or soft lime spots.

It is partly due to this fact, and partly to the greater expense attached to the handling of stone, that almost since the invention of lithography a substitute has been sought for it. Zinc has been used during the last 70 years or more, in its natural state as well as, later on, with a coating embodying the components of the lithographic stone, under the name of "calcsinter" plates. The use of zinc plates as a substitute for stone is, however, confined to the more ordinary grades of work, owing to the inferior and uncertain results obtained. About 1890 John Mullaly experimented with aluminium as a substitute for lithographic stone. His experiments were finally crowned with success, but it was some time before lithographers could be persuaded to make use of it. In the year 1894 Dr. Otto Strecker, of Mainz, Germany, invented a method now called the "Strecker process," for treating aluminium plates with a coating of aluminium salt. This method has come into very general use in Germany, and similar processes are now very considerably used in England, Germany, France, Russia, the United States, and other countries.

Aluminium plates are said to have advantages over stone as to quality of work and, apart from that, to offer all the advantages resulting from their uniform quality, their economy, flexibility, exemption from breaking, and ease of handling and storage. Designs can be removed from either stones or plates by chemical or mechanical means, and their surfaces prepared for the reception of new designs about 200 times in the case of a stone 4 inches thick and of an aluminium plate $\frac{28}{1000}$ of an inch thick. Lithographic crayon is composed of beeswax, shellac, tallow, mastic, turpentine, soap, and lampblack. Lithographic "tusche," or ink, which is used for drawing with the pen, contains the same ingredients, with the grease a trifle more predominant, in a liquid state.

When a drawing, which necessarily is made reversed, is completed on stone, its surface is bathed with a solution of acid and gum arabic. The object of this treatment, called "etching," is to prepare the surface of the stone having no design for the better retention of water; to clear the surface from any imperceptible fatty particles arising from contact with fingers, etc.; and, finally, to render the drawing insoluble in water, by decomposing the alkali contained in the soap which is one of the bases of its composition. After etching, the stone is thoroughly washed, first with water, then with turpentine, which removes every visible trace of the drawing, leaving only the fatty substance of the crayon or ink on the surface. After being repeatedly moistened and rolled in with printing ink it is ready for printing.

Of the various processes employed in drawing on stone, the crayon process is without question the most important. For this purpose the stone is grained. This is done with sand and water between two slabs of stone, which are rubbed together with a circular motion until the lower one has the grain desired—either fine or coarse, according to the nature of the work to be performed. Next in importance is the pen-stipple process. For this purpose the stone is polished with pumice. Stippling consists of drawing with small dots, the values in shading being obtained by the relative density of these dots.

A mode of procedure which differs widely from both crayon and pen-stipple manner is engraving, though based on the same principle. In this case the stone is finely polished and etched and then covered with a dark ground—lampblack and gum arabic dissolved in water. The drawing or writing is scraped into the ground with an engraving needle or a scraper, laying bare the surface of the stone. When the design is finished, the stone is covered with linseed oil, the ground washed off, the surface moistened, and printing ink is applied by means of a dauber, which then adheres only to the lines of the design, by reason of the oil they contain.

Chromolithography. In this either the crayon process, the pen stipple, or a combination of both, is employed. The important feature of this branch of lithography is to obtain a perfect register of the colors to be superposed. To accomplish this, for higher-class color work, a key is made by tracing with an engraving needle on gelatin a complete outline of the original, following even the most minute patches of color. The lines thus engraved on gelatin are filled in with lithographic ink and transmitted to stone by pressure in a hand press. Register marks of thin crossed lines are then added in the margin of top, bottom, and sides, which become the guides for accurate register in printing. The design is then "etched" and rolled up with printing ink, and impressions to the number of colors required are made therefrom. These so-called "offset" or "key" impressions are in turn transmitted to stone by pressure, having first been powdered with a finely ground dry color, which, owing to its fatty qualities, adheres only to the line work. Where a drawing stone is used in place of the key, offset impressions of the same, supplied with the register marks, accomplish the same purpose. The number of colors used varies according to the quality of the work desired. For commercial purposes the number ranges from 3 to 15, and in some cases, where especial results are desired, as many as 20 and 30 colors are used. For monochrome four tints are usually employed—one for the main drawing, a light ground tint, a medium tint for modeling, and finally a dark tint for accents.

Photolithography. In later years photography has been made a valuable adjunct to lithography. One of its applications is photolithography, by means of which pen drawings are faithfully reproduced at comparatively small expense. Another result is the application of the half-tone or Meisenbach process to lithography, for monochromes, and chromolithographs, in which case a photographic reproduction from the original on stone forms the basis for the several color plates, taking the place of the key, subject to the manipulation of the expert chromolithographer.

Of the several methods in use to achieve a photographic reproduction on stone, the oldest one, invented by Niepce in 1833, is based on the property of asphaltum dissolved in oil of lavender to become insoluble when exposed to actinic action. Thus, when a half-tone negative is superimposed upon a stone coated with an asphalt solution, in perfect contact, and exposed to the sun's rays, the asphalt solution will only be affected by such light as can pass through the negative. Dissolving the parts not affected in this manner, by means of turpentine, will produce a positive on stone, which, having in its composition the necessary ingredient, grease, is prepared for printing purposes in very much the same manner as drawing on stone.

The method most generally employed, however, is the albumen process. Albumen in solution with bichromate of potassium has the same properties as the asphaltum solution. It is more sensitive to the chemical action of light, achieving the results desired in a much shorter space of time. After exposure the stone is immediately covered with printing ink to prevent further action. The parts that remain soluble are washed away with water, the ink adhering only to the parts that have become insoluble, thus creating the conditions which are essential for lithographic purposes.

The three-color process is also applied to some extent in lithography, reproducing on stone the three negatives necessary for this process by either of the methods described. Another photolithographic process, which, though still in its experimental stage, deserves mention, is the grain process. The object in view is to substitute, for the geometrical pattern characteristic of half-tone work, a somewhat irregular grain finish which more closely resembles the results of a crayon drawing on stone. Some very fair results have been achieved in this direction.

Transfer Process. The rapid development of the lithographic industry led to the universal adoption of the transfer process, by which the same design can be reproduced as many times at one impression as the size of the sheet to be printed will admit. Impressions from the original stone are made with transfer ink (containing practically the same ingredients as lithographic ink) on paper coated with a sizing of starch and glycerine. The impressions are then laid in their proper position on a sheet of paper and fixed by indentations made with the dulled point of an engraving needle. This sheet is then laid down on a clean polished stone or metal plate and repeatedly pulled through a hand press until all the ink has been transferred from the impressions to the stone or metal plate, the paper being frequently moistened during this process until it can readily be removed. A weak solution of gum and water is applied, the stone is then rolled up with printing ink, and the transfer is finally "etched" in the same manner as an original drawing to make it ready for printing. In chromolithography the first transfer made is that of the key plate containing the register marks. An impression from this transfer, coated with shellac to insure against stretching or shrinking, is mounted on a sheet of zinc or aluminium, and the impressions of all succeeding transfers are "stuck up" or indented on this key sheet, so that all the colors will be in accurate register with each other.

Lithographic Printing. Machinery used for lithographic printing may be divided into two classes, hand presses and power presses. The construction of the lithographic power press varies but slightly from that of the typographic power press. It is operated on the same general principle, except that it has in place of the letterpress form a lithographic stone in its bed, and is supplied with mechanism for applying the moisture to the stone. When the hand press is used, the moistening is done by means of a sponge.

The hand press consists of (1) a movable bed for the stone, resting and traveling on rollers; (2) an impression bar or scraper of boxwood, with a wedge-formed edge, running lengthwise, covered with leather and fitted to a yoke; and (3) a tympan hinged to that end of the bed nearest the impression bar. After the stone has been moistened and rolled up with ink, the paper upon which the impression is to be made is laid upon the stone in the desired position and a backing sheet placed over it; the tympan is lowered to cover the entire stone and bed, the edge of which is then brought forward under the impression bar; the pressure is applied by means of a hand lever at the side of the press, and the entire length of the bed passed under the impression bar. The pressure is then released and the bed brought back to its original position, the tympan raised, and the sheet, having taken the impression, is taken off. This method of hand printing, which before the introduction of the power press was used exclusively for lithographic printing, is now only used for the purpose of making artist proofs and transfers for printing on power presses.

The substitution of the flexible aluminium plate for lithographic stone has resulted in the successful use of rotary printing machinery and has opened the field of multicolor printing by the lithographic process. For this purpose rotary presses are used which print two or more colors in rapid succession before delivering the sheet. The rotary lithographic press consists of two cylinders—one to hold the plate and the other to furnish the pressure. It is supplied with a mechanism similar to that of the flat-bed lithographic press, for distribution and application of moisture and ink. Its speed is about 50 per cent greater than that of the stone or flat-bed press. Rotary presses having two or more plate cylinders and printing two or more colors each time a sheet is fed are already largely in use, and five-color and six-color presses are being made on the same principle.

Offset Lithography. This method of lithographic printing takes its name from the fact that the impression on the paper is taken from an intermediate rubber-covered cylinder in place of directly from the printing surface of stone or aluminium. "Offset" printing has long been used for lithographing on metal, but only recently has the method come into general use for lithographing on paper. The presses are constructed in much the same general way as the standard rotary press, except that the cylinders are smaller in diameter, and there is an additional cylinder covered with a rubber blanket. The inking and damping arrangements are the same on the offset press as on the rotary press.

The work to be reproduced is transferred in the usual manner to the aluminium or zinc plate, which is strapped to the printing cylinder, the same as on the ordinary rotary press. In place, however, of printing the design directly from the aluminium on to the paper, the impression is taken from the aluminium plate on to the rubber-covered cylinder. The paper is then fed through the press in contact with this rubber cylinder and receives the "offset" impression from the rubber cylinder. The rubber cylinder, presenting a slightly yielding printing surface, permits the lithographer to use many beautiful rough-finished and antique papers, which were heretofore unsuitable for lithographic color work and does away with the necessity for highly finished or coated papers for lithographic printing. Photography plays an important part in the operation of this process in the preparation of the original engravings, as it is possible to print delicate half tones, which are utilized as a part of many of the color plates in the finer work done by this method. The only necessary change from the regular method in the preparation of the engravings is that the originals must be placed on stone just as they appear when printed and not in reverse, as in regular lithography. Offset presses are run at a much higher speed than ordinary rotary or flat-bed presses.

HISTORY

Lithography was invented in 1798 by Aloys Senefelder (q.v.), a printer of music from copper plates at Munich. Experiments made while thus engaged led to his discovery of chemical or surface printing. It has been claimed by some that Simon Schmidt, who printed from stone as early as 1788, deserves credit for the invention of lithography; but, as a matter of fact, Schmidt merely substituted stone for metal in relief printing, which has nothing in common with lithography. In 1806 Senefelder established himself at Munich as a lithographic printer. Munich thus became the centre of the art; in 1809 there were no less than seven separate establishments, together with a number of private presses. Conspicuous among the first lithographers of Munich was Ferdinand Piloty, father of Karl Piloty, who in 1808 published together with Strixner a series of copies of old masters, and in 1815 reproductions of the pictures in the Munich Gallery. The inventor died in 1834, since which time there have been few improvements upon his methods, so thoroughly did he cover the field. From Munich the art rapidly spread throughout Europe. After several unsuccessful attempts it was established in Paris by Godfrey Engelmann, a native of Mülhausen (Alsace), in 1816. To him is due the credit of inventing chromolithography, for which the French government granted him letters patent in 1837. In 1816 Franz Hanfstängl visited Munich, and in 1834 he founded the first lithographic house in Berlin. Lemercier had meanwhile established himself in Paris and made great progress in the new art. Of especial importance was the lithograph series designed by Adolf Menzel (q.v.). The first lithographic house in London was established in 1822 by Hullmandel. In America lithography was introduced as early as 1828 by Barnett and Doolittle, in New York City. It remained for Paris, however, to develop lithography as a high art. The climax was reached during the reign of Louis Philippe, by such men as Daumier, Grandville, Travies, and Gavarni, famed for their satirical drawings; Deveria, Delacroix, Johannot, and Gigoux, the delineators of romantic literature; Charlet and Raffet, who glorified on stone the conquests of Napoleon; Géricault and Richard Park Bonington. James Duffield Harding and Alexandre Calame produced some noted landscapes, Eugène Isabey lithographed some very fine marines, and Julien's fame as a lithographic artist culminated in his famous "Etudes en Deux Crayons." With the introduction of the power press lithography soon developed into a world-wide industry. Its applications and accomplishments multiplied to such an extent, not only artistically but commercially, that to enumerate them would be impossible. The most noteworthy feature of its recent development is the modern extensive output of German lithography, practiced in all German art centres by such able exponents as Walther Georgi, Hans von Volkmann, and Otto Fikentscher.

LITHOLAPAXY, lĭth′ṓ-lȧ-păk′sĭ *or* lī-thŏl′-ȧ-păk′sĭ. See Lithotrity.

LITHOL′OGY. See Petrology.

LITH′OMANCY (λίθος, *lithos*, a stone + μαντεία, *manteia*, divination). Divination by means of stones. See Superstition.

LITH′OMARGE (from Gk. λίθος, *lithos*, stone + Lat. *marga*, marl). A name given to the compact earthy varieties of halloysite, kaolinite, and pinite. They are essentially hydrated aluminium silicates, also containing iron oxide and other coloring substances, and are either white, light yellow, or red in color, according to the amount of impurity. These minerals are soft, greasy to the touch, and adhere strongly to the tongue. They are found in Germany, Russia, Cornwall, England, and at various localities in the United States.

LITH′ONTRIP′TICS (from Gk. λίθον, *lithon*, acc. sing. of λίθος, *lithos*, stone + τρίβειν, *tribein*, to rub, to wear out). An old term applied to remedies which, whether taken by the mouth or injected into the bladder, act as solvents for urinary calculus or stone. Those medicines which merely prevent their formation are designated antilithics.

Various medicines have at different times been recommended and employed. Different remedies are selected according to the chemical composition of the calculus. For uric acid calculi, distilled water, the salts of potassium, lithium, and magnesium, piperazin water, and lycetol are given; for phosphatic calculi, benzoic acid, ammonium benzoate, and dilute nitric acid are advised; while, in the case of calcium oxalate calculi, dilute nitrohydrochloric acid and lactic acid are believed to be most efficacious. Examination of the crystalline deposits in urine afford a clew to the character of the stone. Rather more than a century ago, limewater and soap, when swallowed in sufficient quantities, had a high reputation as solvents for urinary calculi. These were the only active ingredients in Miss Stephen's *Receipt for the Stone and Gravel*, which was reported on so favorably by a committee of professional men that the English Parliament, in 1739, purchased the secret for £5000. The treatment doubtless afforded relief; but there is no evidence that any calculus was actually dissolved, for in the bladder of each of the four persons whose cure was certified in the report the stone was found after death. At present no substance is known which, taken by the mouth, has the power of dissolving calculi. The relief which in many instances has followed the administration by the mouth of substances supposed to be lithontriptics has been derived, not from the solution of the calculi, but from the diminution of pain and irritation in the bladder.

LITH′OPHYTE (from Gk. λίθος, *lithos*, stone + φυτόν, *phyton*, plant). A plant that grows on rocks, sometimes underneath the water, as marine algæ. See Benthos; Rock Plants.

LITH′OPONE. See Barite.

LITH′OSPHERE. See Crust of the Earth; Geography.

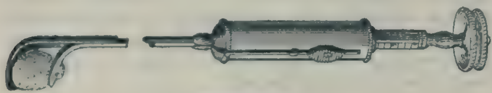
LITH′OSTRO′TION (Neo-Lat., from Lat. *lithostrotus*, mosaic, from Gk. λιθόστρωτος, paved with stone, from λίθος, *lithos*, stone + στρωτός, *strōtos*, covered, from στρωννύναι, *strōnnynai*, to spread). A characteristic coral fossil of the Carboniferous limestones, found in all parts of the world where those rocks are known. This coral, allied to *Cyathophyllum*, forms a rounded mass of more or less closely packed cylindrical or polygonal tubes, the upper ends of which have cells with numerous strong radiating septa and usually also a prominent central conical elevation or columella. About 15 species are known, of which the more common are *Lithostrotion canadense*, of the Mississippi Valley States, and *Lithostrotion junceum*, of Europe and Asia. See Coral.

LITHOT′OMY (Lat. *lithotomia*, from Gk. λιθοτομία, *lithotomy*, from λίθος, *lithos*, stone + τομή, *tomē*, a cutting, from τέμνειν, *temnein*, to cut). The technical name for the surgical operation popularly called *cutting for stone*.

As most of the symptoms of stone in the bladder (see Calculus) may be simulated by other diseases of the bladder and adjacent parts, it is necessary to have additional evidence regarding the true nature of the case before resorting to so serious an operation as lithotomy. This evidence is afforded by *sounding* the patient—a simple preliminary operation, which consists in introducing into the bladder, through the natural urinary passage (the urethra), a metallic instrument, by means of which the stone can be plainly felt and heard. From the shortness of the female urethra and the extent to which it can be dilated, and, additionally, from the comparative rarity of calculous affections in women, the operation of lithotomy is almost exclusively restricted to the male sex.

Lithotomy has been performed in various ways at different times. The earliest form of lithotomy is known as *cutting on the gripe*, or *Celsus's method*. It received the former name from the stone, after being fixed by the pressure of the fingers in the anus, being directly cut upon and extracted; and the latter from its having been first described, so far as is now known, by Celsus, although it had probably been practiced from time immemorial. At a later period this operation received from Marianus the name of the *apparatus minor* (from a knife and hook being the only instruments used), to distinguish it from his own method, which he called the *apparatus major*, from the numerous instruments he employed. The *Marian method* was founded on the erroneous idea that wounds of membranous parts would not heal, while their dilation was comparatively harmless. The object was to do as little as possible with the knife, and as much as possible with dilating instruments; and the necessary result was laceration and such other severe injury that this became one of the most fatal operations in surgery. Nevertheless, it was the operation mainly in vogue for nearly 200 years. At present surgeons, operating by cutting through the perineum (the body between the rectum and the bladder), use a median, or a lateral, or a slightly curved transverse incision, according to individual preference. But either of these methods is suitable only for the removal of a small stone; therefore it is most frequently advisable to remove the calculus by an abdominal incision (suprapubic lithotomy), which was first employed by Franco in 1561. By this method the opening is made first above the pubes, and the bladder is entered without cutting the peritoneum. Cutting operations for stone are not much practiced in modern surgery, the procedure known as lithotrity (q.v.), or crushing, being employed instead. In this method an ingenious instrument with powerful jaws is introduced through the urethra into the bladder, the stone seized and crushed into small fragments and washed out with water. When the stone is very large or encysted, or the urethra narrowed by undilatable stricture, lithotomy must be the operation of choice. For details of treatment, consult White and Martin, *Genito-Urinary Surgery and Venereal Diseases* (Philadelphia, 1906), and Walker, *Surgical Diseases and Injuries of the Genito Urinary Organs* (New York, 1914).

LITHOT′RITY (from Gk. λίθος, *lithos*, stone + Lat. *tritus*, p.p. of *terere*, to rub, to grind). The surgical operation of breaking up a stone in the bladder into such small fragments that they may readily be expelled through the urethra. Although the importance of such an operation has been recognized from the earliest times, a French surgeon, Civale, who commenced his researches in 1817, but did not perform his first operation till the beginning of 1824, is entitled to be regarded as the discoverer of lithotrity. The instrument by which the disintegration of the stone is effected is introduced in the same manner as a catheter or sound into the bladder, and, after catching the stone, crushes it to pieces, the stone being grasped by the blades of the instruments, one blade acting on the other by means of a screw. The small fragments are then washed out of the bladder by means of a special apparatus, called by Bigelow an evacuator. Great care must be taken that no fragment remains in the bladder, as it would surely form the nucleus of a new stone.



LITHOTRITE.

The process seems, at first sight, so safe, as compared with the operation of lithotomy, that it is necessary to distinguish those cases in which it may be resorted to and those in which it is contraindicated. It may be resorted to when the patient is an adult, and the urethra full-sized and healthy, so as freely to admit the passage of the instrument; it must be avoided in children, in consequence of the smallness of the urethra, and also when there is great irritation and thickening of the bladder; when there is great enlargement of the prostate, which hinders the manipulation of the instrument and the escape of the broken fragments of stone; when the stone is of large size, as, e.g., of a greater diameter than 2 inches; and when there is reason to believe that the concretion is a "mulberry" calculus which, from its extreme hardness, cannot readily be broken.

Litholapaxy is the term used to denote an operation by which the fragments of the stone are removed at the same time the stone is crushed. This procedure was made possible by the perfection of the instruments by Bigelow, of Boston, Mass., in 1878, Otis, of New York, having taught that instruments of large size can be introduced safely into the bladder. Consult White and Martin, *Genito-Urinary Surgery and Venereal Diseases* (Philadelphia, 1906), and Walker, *Surgical Diseases and Injuries of the Genito Urinary Organs* (New York, 1914).

LITHUANIA, lĭth′ū-ā′nĭ-ȧ (Lith. *Letuva*). A new state formed out of Russian territory after the European War. The limits were defined by a treaty with Russia, signed July 20, 1920, as follows: From the Duina River, west from Drujka, along the Drujka River and eastern shore of Lake Narocz and the Narocz River, and then through the railway junction of Molodecno along the Berezina and Niemen rivers to a point a short distance south of the city of Grodno. According to the claims of the Lithuanian government the country comprised all the former Russian Province of Kovno; all but two districts of the Province of Vilna; most of the Province of Suwalki; part of the Province of Grodno; and part of the Province of Courland. The northern frontier with Latvia nearly coincides with the former boundary between the old Russian provinces of Courland and Kovno. The estimated area is 60,000 miles and the estimated population 6,699,200. The capital is Vilna which had a population of 214,600. See SUPPLEMENT.

This region was formerly, and is still in great part, covered with forests and marshes, and the soil is very unproductive. The chief rivers are the Dnieper, Pripet, Berezina, Duina, Niemen, and Bug. The inhabitants are Lithuanians, Russians, Poles, and Jews. The early history of Lithuania is very obscure. Having no natural boundaries, it was anciently subject to constant invasions by its neighbors. But as the Lithuanians had no fortified towns to be captured, and as the woods and marshes were almost impassable, the country remained practically independent. The people were little advanced in civilization and had no central government until the latter part of the Middle Ages. They clung tenaciously to their pagan beliefs and practices, and it was only about the beginning of the fifteenth century that Christianity was established, the nation accepting the Roman Catholic faith. Early in the thirteenth century one of the chiefs, named Ryngold, whose personality is bound up with legend, is represented as having instituted a central government; the first clearly historic character, however, is Ryngold's son, Mendowg, who received recognition from Innocent IV in 1251 and reigned over Lithuania till about 1263. At this time the Teutonic Knights were establishing their power in the Baltic regions, spreading Christianity with fire and sword, and the bloody wars waged with them are a prominent feature in the early history of the Lithuanian principality. Fierce wars were also carried on against the Russians. Gedywin (1316–1341) wrested vast territories from Russia, including Volhynia and Vitebsk. In 1386 Jagiello, Grand Prince of Lithuania, married Jadviga, daughter of Louis the Great of Poland, and mounted the Polish throne, having been previously baptized. For 100 years from the time of Jagiello Lithuania and Poland had separate rulers, a loose political union existing between the two countries. From 1501 they had a common sovereign, and in 1569 the Diet of Lublin decreed the permanent union of Poland and Lithuania into one commonwealth, to be governed by an elective king. Henceforth the history of Lithuania is that of Poland. (See JAGELLONS; POLAND; RUSSIA.) Consult: Joachim Lelewel, *Histoire de la Lithuanie* (Paris, 1861); Theodor Schiemann, *Russland, Polen und Livland bis ins 17te Jahrhundert* (2 vols., Berlin, 1886–87); Zoladz, *Histoire de la Lithuanie* (Paris, 1902).

LITH'UA'NIAN LANGUAGE AND LITERATURE. The language and literature of about 2,000,000 Lithuanians, the great bulk of whom live in the Russian governments of Kovno, Vilna, Grodno, and Suwalki (the last in Poland). There are about 100,000 in the Prussian Province of East Prussia, and a number have emigrated to the United States. With the Lettic (q.v.) and Old Prussian (q.v.) the Lithuanian constitutes the Baltic subdivision of the Balto-Slavic group of the Indo-Germanic family of languages. The earliest Slavic literary records antedate the oldest Lithuanian records by seven centuries, yet the Lithuanian is more archaic than the Slavic in phonology, although in morphological structure it is less primitive. It has long, short, and half-long vowels, of which the Slavic, excepting the Servian and Czech, has no relics. The Lithuanian employs three accents: for short vowels, the grave; for long vowels, either the acute to mark a "falling" tone, e.g., *kó-tas*, 'steel,' or the circumflex to mark a compound "rising-falling" tone, e.g., *rã-tas*, 'wheel.' Like Sanskrit and Slavic, the Lithuanian accent is entirely free, often receding to the fifth syllable from the end, shifting from the root upon the affix and vice versa, e.g., *sukù*, 'I turn,' *súka*, 'he turns'; Skt. *dvēṣmi*, 'I hate,' *dviṣmás*, 'we hate,' *á-dvēṣam*, 'I hated'; Lith. *rankà*, 'hand,' gen. sing. *rañkos*.

Among the most notable phonological characteristics of the Lithuanian language are the retention of diphthongs: *véidas*, 'face, view,' Gk. *Ϝεῖδος*, Slav. *vidŭ;* Lith. *baisùs*, demon, Slav. *bēsŭ;* the retention of the primitive endings of nouns: Lith. *vĩlkas*, 'wolf,' Skt. *vṛkás*, Slav. *vlŭkŭ;* the complete loss of *h*, and the change of the aspirates to tenues: the German words *Christus, Franzose* are *Kristùs, Prancūzas* in Lithuanian. As in Slavic and Indo-Iranian, Indo-Germanic *k* became a sibilant: Indo-Ger. **km̊tó-m*, hundred, Lith. *szim̃tas*, Skt. *śatám*, Av. *satəm*, Slav. *sŭto*, Gk. *ἑκατόν*, Lat. *centum*.

In morphology, the Lithuanian has generally preserved the terminations remarkably intact. It has seven of the eight Indo-Germanic cases, and the three numbers; the neuter gender appears in pronouns only. There is no trace of the article, though, as in Old Church Slavic and Russian, the postpositive use of *ya* changes an adjective from the indefinite to the definite form. The verb makes the third singular do duty for the third person of all three numbers; it possesses four tenses: present, preterite, future (formed by the addition of *-siu*, Indo-Ger. *oso*, Skt. *-sya*, Gk. *σ*, e.g., Lith. *dusiu*, Skt. *dāsyāmi*, Gk. *δώσω*, I shall give), and imperfect; there are distinct forms for the indicative, optative, imperative, infinitive, and participle. The passive is periphrastic throughout, but the active construction is substituted whenever possible. A reflexive voice also is formed by the addition of *-s* (earlier *-si*, reflexive pronoun) to the active forms.

In its vocabulary the Lithuanian has drawn to a considerable extent from the German, Russian, and Polish. Its numerous dialects fall into two groups: the High (Southern) Lithuanian, which changes the combinations *ty* and *dy* to *cz*, *dz*, and the Low (Northern) Lithuanian, which retains *ty* and *dy*.

The earliest printed literary remains in Lithuanian are a translation of Luther's smaller Catechism (Königsberg, 1547); a baptismal formulary (dating from 1559); another translation of Luther's Catechism and the Gospels (1579), and the prayer books and translation of the Bible by the preacher Jan Bretkun (1535–1602). On it was based the excellent *Psalter* of Rhesa (1629). The earliest Catholic Lithuanian book was a translation by Michael Dauksza of a Polish Catechism (1595). It is a remarkable fact that in another work, published in 1599, Dauksza claims for the Lithuanian literary equality with Polish, Latin, and Greek. By 1701, 59 books had been printed in Lithuanian, but most of them were destroyed by unknown hands. To the Calvinist propaganda the Lithuanian owes its development for literary purposes, and the publication of a Calvinist New Testament (1701) marks the new period, when works of other than liturgical purport began to appear. The most important name during this period is that of the poet Christian Donalitius (1714–80). His pastoral epic, *The Four Seasons*, in hexameters, displays uncommon powers of observation and a facile style. This poem and six extant fables were published by Schleicher (St. Petersburg, 1865) and Nesselmann (Königsberg, 1869), with translation, notes, and glossary. Another important work was Philipp Ruhig's *Lithuanian Dictionary* (1749), later reëdited by Milke, with a preface by the philosopher Kant. The publications until the last quarter of the nineteenth century were mainly religious, although between 1801 and 1891 some 1200 different books were printed. The distinguished lexicographer Kurschat (1806–84) revised the Lithuanian New Testament and edited from 1849 to 1880 the weekly *Keleiwis* ("Traveler"). Simon Dowkont (1793–1864) collected important folklore materials. In 1861 Olechnowicz published fables and stories from Lithuanian life, and later the Bishop Baranowski (died 1902) wrote an epic, the *Onikshta Grove*. Fritz Kelch (1801–77) issued the first Prussian-Lithuanian newspaper, and in 1883 *Auszra* (*Dawn*), the first magazine, the organ of the Young Lithuanian party, was founded by Basanowicz. From 1834 to 1895 some 34 periodicals appeared in the United States.

LITHUANIANS. A branch of the Letto-Lithuanian group of the Aryan family, living mainly in European Russia, between the White Russians and the Baltic and also in the United States; height, 1.643 meters in Lithuania and 1.639 meters in Poland. Their number is estimated at some 2,000,000. They are well made, blond, and with oval face, long, thin nose, thin lips, blue eyes, white skin, and light hair. They are said to exhibit elements of sub-Northern and Eastern race. They are largely husbandmen, wagoners, and woodmen. The Russian census of 1897 put the total number of Lithuanians and Letts at 3,094,069.

LITHUANIAN VERSION. See Bible.

LITHU'RIA. See Lithic-Acid Diathesis.

LITITZ, lit'its. A borough in Lancaster Co., Pa., 27 miles southwest of Reading, on the Philadelphia and Reading Railroad (Map: Pennsylvania, J 7). It is a popular summer resort, its attractions including the famous Lititz Springs, and has Linden Hall Seminary, established by the Moravians in 1794. Among its industrial establishments are knitting mills, chocolate and cocoa works, planing mills, and manufactories of cigars, animal traps, shoes, box board and paper, liquor, and pretzels. Pop., 1900, 1637; 1910, 2082. Lititz, founded by Moravians (q.v.) in 1757, was named after a village in Bohemia whence some of the forefathers of the Unitas Fratrum had emigrated, and was organized from Warwick township. The Brothers' house, built in 1759, was used as a hospital during part of the Revolutionary War, and a number of soldiers died and were buried here. Consult: *Moravian Historical Society Transactions*, vol. ii (Bethlehem, Pa.), and Mombert, *An Authentic History of Lancaster County, Pa.* (Lancaster, 1869).

LIT'MUS (corruption of *lacmus*, from *lac*, from Pers. *lak*, lac, from Skt. *lākṣā*, lac insect, from *lakṣa*, hundred thousand; so called from the great numbers of the insect in a single nest). A coloring matter of vegetable origin. Acids turn blue litmus red; alkaline solutions, on the contrary, turn red litmus blue. In laboratories litmus is used either in the form of a solution, or in the form of test paper impregnated with it. Litmus is manufactured principally in Holland, from *Lecanora tartarea* and other lichens. The process employed is similar to that used in the manufacture of archil (q.v.); the lichens are ground into a pulp with water, and potassium carbonate and ammonia are added. Under the action of these substances and of atmospheric air, the mass gradually assumes a blue color, owing to the formation of the coloring principles of litmus. Chalk or gypsum is then added, to render the mass thick enough to be formed into rectangular cakes, which are dried and brought into the market. The chemistry of litmus is but little known; the following, however, have been shown to be its chief coloring principles, viz., azolitmin, whose brownish-red color is turned blue by ammonia; purplish-red erythrolein, which, by the action of alkalies, is turned purple; and erythrolitmin, whose red color is changed by alkalies to blue. These coloring substances exist in commercial litmus in the form of lakes, i.e., combined with metallic hydroxides.

LIT'OLFF, Henry (1818–91). A European pianist and composer. He was born in London, studied the piano under Moscheles for several years, and in 1832 made his professional début in London. He went to France and then wandered around Europe giving concerts until 1851, when he settled in Brunswick and married the widow of the music publisher Meyer, of whose business he took charge. In 1860 he transferred the business to his adopted son Theodor, who in the following year started the cheap edition of classical music called Collection Litolff. As a pianist, Litolff was brilliant, passionate, but uneven. His compositions were melodious and his piano pieces (for example "Spinnlied") were popular. Of his other works the most noteworthy are: the symphony concertos Nos. 3, 4, and 5; the oratorio *Ruth et Boaz* (1869); a funeral march for Meyerbeer; the operas *Die Braut vom Kynast* (1847) and *Les Templiers* (1886); and the operetta *Héloïse et Abélard*. He died in Paris.

LIT'TA, Pompeo, Count (1781–1852). An Italian historian. In 1804 he entered the French army and participated in the campaigns in Germany. In the Italian revolutionary epoch of 1848 he was for a short time Secretary of War for the Provisional Government of Milan. He was the author of the comprehensive work entitled *Famiglie celebri d' Italia* (1819–38), embracing 53 histories, to which more have been added by Odorici, Passerini, and others.

LITTELL', Eliakim (1797–1870). An American editor and publisher, born in Burlington, N. J. He began in 1819 to edit and publish in Philadelphia the *National Recorder*, which, changed in 1821 to the *Saturday Magazine*, first published in America De Quincey's *Confessions of an English Opium-Eater*. In 1822 he established the *Museum of Foreign Literature, Science, and Art*, and in 1844 founded in Boston *Littell's Living Age*, later known simply as the *Living Age*.

LITTER. See Hospital.

LIT'TLE, Arthur Dehon (1863–). An American chemical engineer. Born in Boston, he studied at Massachusetts Institute of Technology in 1881–84; was chemist and superintendent of a paper mill at Providence, R. I., in 1884–85; and served as State assayer in Massachusetts in 1887–95. After 1886 he was a consulting chemist in Boston; became president of the chemical engineering company of Arthur D. Little, Inc., of the Chemical Products Company, and of the Fibre Finishing Company; and he lectured at Harvard University and Massachusetts Institute of Technology. In 1912–13 he was president of the American Chemical Society. He is author of *The Durability of Paper* (1903); *The Basis of Quality in Paper* (1910); *Earning Power of Chemistry* (1911); *Industrial Research in America* (1914).

LITTLE, Charles Coffin (1799–1869). An American publisher, born at Kennebunk, Me. In 1837 he founded the firm of Charles C. Little & Co., later Little, Brown & Co.

LITTLE, Charles Joseph (1840–1911). An American Methodist Episcopal clergyman and educator, born in Philadelphia. He graduated from the University of Pennsylvania in 1861 and studied in Europe from 1869 to 1872, part of the time under the noted scientist Helmholtz. He received the degree of Ph.D. from De Pauw University in 1882. He joined the Philadelphia conference of his church in 1862, subsequently being transferred to the Northern New York conference and finally to the Rock River conference. He was professor of mathematics in Dickinson Seminary (1867–68); of philosophy and history in Dickinson College (1874–85); of logic and history in Syracuse University (1885–91); and of Church history in Garrett Biblical Institute (1891–1911). Of this institute he was president from 1895 until his death. He was a delegate to the Methodist Centennial Conference held at Baltimore in 1884, and a delegate to a number of general conferences. In 1900 he delivered the Fernley lecture on "Christianity and the Nineteenth Century" before the British Wesleyan Conference. A linguist of ability and distinguished as a scholar, he wrote: *The Angel in the Flame* (1904); "The Religious Revival in History" in *The Revival, a Symposium*, edited by J. H. MacDonald (1905); "The Social Activities of John Wesley" in *The Social Ministry*, edited by Harry F. Ward (1910). Consult C. M. Stuart (ed.), *In Memoriam, Charles Joseph Little* (Chicago, 1912), which contains eight of his papers.

LITTLE, Thomas. The nom de plume of Thomas Moore.

LITTLE, William John Knox. See Knox-Little.

LITTLE BEAR. The constellation Ursa Minor.

LITTLE BECSKEREK. See Becskerek.

LITTLE BELT. See Belt.

LITTLEBOROUGH, lĭt′t'l-bŭr-ō. A manufacturing town of Lancashire, England, 3 miles northeast of Rochdale. Pop., 1901, 11,160; 1911, 11,697.

LITTLE BRITAIN. A small neighborhood in the centre of London, during the time of the Stuarts a famous quarter for booksellers. Its name was derived from the former residence there of the dukes of Brittany.

LITTLE CAUCASUS. See Caucasus.

LITTLE CAYMAN. See Caymans.

LITTLE CHIEF HARE. A book name, derived from the Indians, for the pika of the Rocky Mountains. See Pika.

LITTLE COLORADO, or COLORADO CHIQUITO. One of the principal tributaries of the Colorado River. It rises on the slopes of the White Mountains in the southern part of Apache Co., Ariz., and flows northwestward across the Painted Desert, joining the Colorado proper at an altitude of 2625 feet above the sea (Map: Arizona, D 2). Its drainage basin has an area of about 6000 miles, and its principal tributary is the Rio Puerco, which joins the main stream 2 miles above Holbrook. For the last 27 miles of its course it has cut into the plateau a cañon over 1800 feet deep.

LITTLE CORPORAL. An affectionate nickname given to Napoleon Bonaparte after the battle of Lodi on account of his youthfulness and small size.

LITTLE CROW (1810–63). A Sioux Indian chief. In 1851 the Sioux or Dakota Indians ceded most of their lands in the present State of Minnesota to the national government and removed farther north to lands which proved unsatisfactory. Though Little Crow had been influential in bringing about the transfer, he took advantage of every opportunity to create dissatisfaction. Some young men of the tribe murdered some settlers in 1862, and Little Crow urged a general massacre, claiming that the South would win in the Civil War then being waged, and that the government could not punish them. On Aug. 18, 1862, the whites at two agencies were massacred, and it is estimated that 1000 settlers were killed. Ex-Governor Sibley was appointed to the command of a military expedition and completely defeated the Indians at Wood Lake. Two thousand Indians and many whites held as prisoners were taken, and 303 Sioux were condemned to death by a military court; but President Lincoln intervened, and only 38 were executed. Little Crow fled, but was shot by a settler the next year. Much information on this raid may be found in *Collections of the Minnesota Historical Society*, vol. vii (St. Paul, 1887–94).

LIT′TLEDALE, Richard Frederick (1833–90). A controversial Anglican writer. He was born in Dublin, graduated at Trinity College, Dublin, 1854, and was ordained a minister of the Church of England, 1856. After a few years of parochial service in London, where he interested himself in charities, he resigned his charge in 1862 and devoted himself to authorship, making a special study of liturgies and of the relations between the national church and dissenting bodies. He was author of many works, including *Catholic Ritual in the Church of England, Scriptural, Reasonable, and Lawful* (1865); *Church Reform* (1870); *Plain Reasons against Joining the Church of Rome* (1880). He also contributed much to periodicals and was editor of the *Church Times*.

LITTLE DORRIT. A novel by Charles Dickens, which appeared serially from 1855 to 1857, and the nickname of its heroine, Amy Dorrit. See Dorrit, Amy.

LITTLE ENGLAND. A name given to Barbados.

LITTLE FALLS. A city and the county seat of Morrison Co., Minn., 98 miles by rail northwest of Minneapolis, on the Mississippi River and on the Northern Pacific Railroad (Map: Minnesota, C 5). It has a city library and two fine hospitals and a courthouse. Little Falls is the commercial centre for a productive agricultural and lumbering district and manufactures lumber, paper, flour, beer, agricultural implements, and bricks. The dam across the river here furnishes extensive water power. First settled in 1849, Little Falls was incorporated in 1889. The government is vested in an annually elected mayor and a municipal council. Pop., 1900, 5774; 1910, 6078.

LITTLE FALLS. A city in Herkimer Co., N. Y., 21 miles by rail east by south of Utica, on the Mohawk River, the Erie Canal, and the New York Central and Hudson River Railroad (Map: New York, F 4). It has a picturesque location on the slope of a narrow and rocky defile, flowing through which the river falls 45 feet in less than a mile, forming a number of cascades—the origin of the city's name. Good water power has contributed to the development of the city as a manufacturing centre; its products include knit goods, knitting machinery, paper, leather, dairy machinery, felt shoes, bicycles, incubators, mattresses, bookcases, etc. The city has a public library and a city hospital. There are municipal water works. A small settlement here was destroyed by the Indians and Tories in June, 1782, and the place was not resettled until 1790. Little Falls was incorporated as a village in 1811, reincorporated in 1827, and in 1895 was chartered as a city. On the outskirts is the grave of General Herkimer, of Revolutionary fame, with a monument erected in 1896. Pop., 1900, 10,381; 1910, 12,273; 1914 (U. S. est.), 13,077; 1920, 13,029.

LITTLE FERRY. A borough in Bergen Co.,

N. J., adjoining Hackensack, situated on the Hackensack River and on the New York, Susquehanna, and Western, the New York, Ontario, and Western, and the West Shore railroads. The chief industries are the manufacture of bricks and pearl buttons and the raising of garden truck for New York markets. Pop., 1900, 1240; 1910, 2541.

LITTLE GENTLEMAN IN VELVET. The name under which, in the reign of Queen Anne, toasts were frequently drunk by the Jacobites to the mole which was the ultimate cause of the death of William III. The King's horse stumbled against a molehill, throwing his rider, whose injuries brought on the illness of which he died in 1702.

LITTLE GIANT. A nickname applied to Stephen A. Douglas, referring to his great intellect combined with small size.

LITTLE ILIAD. See Lesches.

LITTLE INAGUA. See Inagua.

LITTLE JOHN. A companion of Robin Hood, the lieutenant of the band of outlaws. His real name is said to have been John Nailor. He was exceedingly powerful and was the only member of the band who could vie with the chief in shooting.

LIT'TLEJOHN, Abram Newkirk (1824–1901). An American Protestant Episcopal bishop. He was born at Florida, N. Y., graduated at Union College in 1845, and was rector of Christ Church, Springfield, Mass. (1850), of St. Paul's Church, New Haven (1851–60), and of the church of the Holy Trinity, Brooklyn, N. Y. (1860–69). While at New Haven, he also served as lecturer on pastoral theology in Berkeley Divinity School at Middletown. The diocese of Long Island having been constituted in 1868, Dr. Littlejohn was elected its bishop and was consecrated in 1869. Appointed in 1874 to take charge of the American Episcopal churches in Europe, he consecrated the church of St. Paul's Within the Walls, Rome, and opened the American Church in Paris. Besides sermons, charges, contributions to periodicals, etc., he published *Individualism: Discourses before the University of Cambridge, England* (1880), and *The Christian Ministry at the Close of the Nineteenth Century* (1884), lectures before the General Theological Seminary, New York.

LITTLE KANAWHA (kȧ-ną'wȧ) **RIVER.** A river of West Virginia, which rises in Upshur County and flows in a northwesterly direction into the Ohio at Parkersburg (Map: West Virginia, C 3). Its length is little over 100 miles. It is of some importance as an outlet for the products of the lumber and oil regions through which it flows. Slack-water navigation for 40 miles to Burning Springs has been procured by means of locks and dams.

LITTLE LAKE INDIANS. See Pomo.

LITTLE LORD FAUNT'LEROY. A popular child's story by Frances H. Burnett, originally published in *St. Nicholas* (1885).

LITTLE MAC. A nickname given by his soldiers to Gen. George B. McClellan.

LITTLE MAGICIAN. A nickname of President Martin Van Buren, given because of his skill in politics.

LITTLE NAMAQUALAND. See Namaqualand, Little.

LITTLE NELL. In Dickens's *Old Curiosity Shop*, a child who preserves the beautiful purity of her character in spite of her surroundings. See Old Curiosity Shop.

LITTLE PHIL. A nickname given by his soldiers to Gen. Philip H. Sheridan.

LITTLE RED RIDING-HOOD. A well-known fairy tale. Though a very old story, it appears for the first time in its present form in Charles Perrault's *Contes du temps passé*, published in 1697, as "Le petit chaperon rouge." Perrault wrote the tales from a nurse's story, it is said; but they became known in France through Straparola's tales in *Piacevoli notti*, published in 1550, and Basile's *Pentamerone* of 1637.

LITTLE ROCK. The largest city of Arkansas, State capital, and the county seat of Pulaski County, on the Arkansas River, 128 miles west-southwest of Memphis, Tenn., on the Rock Island, the St. Louis Southwestern, and the St. Louis, Iron Mountain, and Southern railroads (Map: Arkansas, C 3). It is built on a rocky bluff, 50 feet above the river, which is here spanned by three railroad bridges and a county bridge. The streets are regular and finely shaded. Little Rock is the seat of Philander Smith College (Methodist Episcopal), the Arkansas Baptist College (colored), Shorter College (colored), and of the medical and law departments of the University of Arkansas. It has, besides the State Capitol, a United States courthouse, Fort Logan H. Roots, the State penitentiary, State School for the Blind, the Arkansas Hospital for Nervous Diseases, the State Reform School, and the State Deaf-Mute Institute, Children's Home, Old Ladies' Home, City Hospital, Pulaski County Hospital, and St. Vincent's Infirmary. There are the Supreme Court, the State, Carnegie, and collegiate libraries, and a United States Weather Bureau station. The system of public parks includes about 400 acres, the most attractive parks being City and West End. Little Rock has large wholesale interests and an important trade, by river and rail, in cotton, lumber, bauxite ore, agricultural produce, and in its own manufactured products. The more important industrial enterprises include cotton gins and presses, with an extensive output of cottonseed oil and cake; foundries and machine shops, bauxite crushing plants, ice factories, railroad shops, planing mills, granite quarries, cotton, twine, furniture, and stave factories, flouring mills, brick and tile works, etc.

The government is vested in a mayor, elected every two years; a unicameral council, and administrative officials as follows: chiefs of police and fire department, city electrician, and police matron, appointed by the executive; city physician, street commissioner, superintendent of public works, and collector, elected by the council; and city clerk, attorney, police judge, and treasurer, chosen by popular election. The municipal income in 1913 was $1,469,000, while the budget balanced at $1,669,000, the principal items of expense being $176,000 for schools, $79,000 for the fire department, and $55,000 for the police department, including amounts for police courts, jails, reformatories, etc. Pop., 1860, 3727; 1880, 13,138; 1900, 38,307; 1910, 45,941; 1914 (U. S. est.), 53,811; 1920, 64,997. Little Rock was settled in 1814. Six years later, with a population of less than 20, it became the seat of the Territorial government, though it was not incorporated until 1831, when its population numbered about 500. During the Civil War it was captured, Sept. 10, 1863, by a Union force under General Steele. Consult Powell, *Historic Towns of the Southern States* (New York, 1900).

LITTLE SCHÜTT ISLAND. See Schütt.

LITTLE SNAKE ISLAND. See Anguilla.

LITTLE TIBET. See Baltistan.

LITTLETON, lĭt′tl′ton. A town in Grafton Co., N. H., 111 miles by rail north by west of Concord, on the Ammonoosuc River, and on the Boston and Maine Railroad (Map: New Hampshire, F 4). The superb scenery of the White Mountains makes it popular as a summer resort. The great water power from the river has developed the manufacturing interests, the principal products being whetstones, gloves, shoes, bobbins, and excelsior. There is a Carnegie library and a hospital. Littleton was settled in 1770 and was known as Apthorp until 1784, when it was incorporated under its present name. The water works and electric-light plant are owned by the town. Pop., 1900, 4066; 1910, 4069. Consult *Granite Monthly*, vol. v (Concord, N. H., 1881), and *History of the Town of Littleton* (3 vols., Cambridge, Mass., 1905).

LITTLETON, Edward, Lord (1589–1645). An English jurist, born at Munslow, Shropshire. He graduated at Oxford in 1609 and was appointed Chief Justice of North Wales in 1621, succeeding his father. In 1626 he was elected to Parliament and in 1628 was chairman of the committee of grievances in whose report was the substance of the Petition of Right. In 1631 he was appointed Recorder of London, and in 1634 he was made Solicitor-General. He became Chief Justice of Common Pleas in 1640 and Lord Keeper of the Great Seal in 1641, with the title of Lord Littleton of Munslow. In 1642 he escaped with the Great Seal to Charles I at York, in 1643 was required by Parliament to restore it on pain of losing his place, and in 1644 was appointed First Commissioner of the Treasury.

LITTLETON, Sir Thomas (1402–81). An eminent English judge and law writer. He was born at Frankley Manor House in the northern part of Worcestershire and was educated at the Inner Temple. His earliest public services were as escheator of Worcestershire, undersheriff of Worcestershire, and recorder of Coventry. As reader to the Inner Temple, he lectured on the Statute of Westminster II, *De Donis Conditionalibus*. In 1453 he became a sergeant at law. In 1455, a few days before the opening battle of the Wars of the Roses, he was appointed one of the King's sergeants at law, and he was reappointed in 1461, when Henry VI was deposed and Edward IV assumed the crown. While King's sergeant, he had much experience of a judicial nature, being frequently in commissions of the peace, of oyer and terminer, and of assize. In 1466 he was made a judge of the Common Pleas. In 1470, when Henry VI was restored, Littleton, like the other judges, was reappointed, and he was also reappointed in 1471, when Edward IV displaced Henry VI permanently. While judge of the Common Pleas, he was in many commissions of oyer and terminer and of the peace, particularly for Worcestershire and counties to the west and north. In 1475 he was made by Edward IV a Knight of the Bath. He died in 1481 and was buried in Worcester Cathedral. His tomb, prepared by himself, is still in existence. The famous treatise by which Littleton is best known, *The Tenures*, which has been correctly described as one of the most famous books ever published, was written towards the close of the author's life, as a book of instruction for his son, and gives a picture of the law of land under the feudal system. It is noted for accuracy and clearness. The first edition appeared in 1481 or 1482, being one of the earliest books printed in London and the earliest treatise on English law printed anywhere. The second edition was printed about 1483 in London, and the third about 1490 at Rouen. These editions and many others were in the original Law French. There have also been many editions in English. In 1628 appeared the celebrated commentary of Coke. There have been about 25 editions of Coke upon Littleton and about 90 editions of *The Tenures* without the commentary. With or without commentary, *The Tenures* formed an important part of legal education for almost three centuries and a half and is still cited in the courts of England and the United States as an authority on the feudal law of real estate. For biographical and bibliographical details, consult Professor Wambaugh's learned introduction to the 1903 edition of *The Tenures* (Washington).

LIT′TLE TURTLE (?–1812). A celebrated Indian chief of the Miami nation, distinguished for his ability, shrewdness, and courage. He commanded the Indian force which defeated General Harmer on the Miami River in 1790 and that which defeated General St. Clair at St. Mary's in 1791, participated in the battle of Fallen Timbers in 1794, and was one of the chiefs who signed the Treaty of Greenville in 1795. In 1797 he visited President Washington in Philadelphia.

LITTLE WOMEN. A popular child's story by Louisa M. Alcott (1868).

LITTMANN, lĭt′mȧn, Enno (1875–). A German Orientalist. He was born in Oldenburg and early undertook important travels in Abyssinia, Syria, and Palestine. After being lecturer on Semitic philology for several years at Princeton University, in 1906 he went to Strassburg as professor of Semitic languages, returning to this chair after spending the years 1910–12 at the University of Egypt. He had accompanied the Princeton archæological expeditions to Syria and to Abyssinia and in 1906 was a member of the German Axum expedition. Besides his part in the publications of the reports of these expeditions, he wrote: *Arabische Schattenspiele* (1901); *Zur Entzifferung der Safâ-Inschriften* (1901); *The Chronicle of King Theodore of Abyssinia* (1902); *A List of Arabic Manuscripts* (1904); *Zur Entzifferung der thamudenischen Inschriften* (1904); *Philosophi Abessini* (1904); *Geschichte der äthiopischen Litteratur* (1907); *Arabische Beduinenerzählungen* (1908); *Nabatæan Inscriptions* (1913).

LITTRÉ, lē′trā′, Maximilien Paul Emile (1801–81). A French lexicographer, philosopher, and physician, born in Paris, Feb. 1, 1801. The life of Littré was neither brightened nor marred by dramatic incidents. His history is that of his mind, which was one of the most clear and energetic of the nineteenth century. Littré's capacity for work was prodigious, his interests universal. Having studied at the Lycée Louis-le-Grand, he became secretary to Count Daru; then he was a student of medicine and an interne. The death of his father set Littré to teaching modern languages and mathematics, but meanwhile he was deep in the ancient tongues, including Sanskrit, and may have studied other Oriental languages. He shared in the upheaval of 1830 as a Democrat, working with Armand Carrel on the *National*. In 1839 he joined the Académie des Inscriptions et Belles-Lettres. About the same time he espoused the positive philosophy (see POSITIVISM), but his mind sought other paths than Comte's. Auguste Comte (q.v.) lacked Littré's knowledge of biology. Littré was less mathematical than Comte, but Littré would have nothing to do with the mysticism of Comte's old age. In 1863 he published *Auguste Comte et la philosophie positive*, partly as a tribute to his former master, partly to set forth his modifications of this philosophy. In 1871 Littré, who had against his will lived in Bordeaux during the siege of Paris, was made professor of history and geography at the Ecole Polytechnique at Bordeaux, but he lectured only once. Dec. 30, 1871, eight years after his first candidacy, Littré was elected to the chair left empty by Villemain in the Academy. In 1871 Littré was a member of the National Assembly, and in 1875 he was elected life member of the Senate. To medicine Littré contributed *Choléra oriental* (1832), a translation of Hippocrates (1839–61), and, with Robin, a new edition of Nysten's *Dictionnaire de médecine*. In this work occurs his definition of man as "a mammal of the order of primates, of the class with two hands," etc.—a definition which enraged Dupanloup. Littré's *Médecine et médecins* (1872) and his translation of Müller's *Handbook of Physiology* (1846), with his translation of Pliny's *Natural History* (1848–50), are notable, as is the translation of Strauss's *Life of Jesus* (1839–40); but Littré's greatest work is the *Dictionnaire de la langue française* (1863–72; Supp. 1877), which he was encouraged to make by his friend the publisher Hachette (q.v.). Littré was well fitted for his task, which he began upon about 1844. His vast learning, his previous experience in lexicography, his lucidity, his patience, and his energy stood him in good stead. Above all, Littré began his *Dictionnaire* when Romance philology had already become modern, and he knew how to avail himself of the best. The history of this thesaurus Littré has told in *Comment j'ai fait mon dictionnaire* (new ed., Paris, 1897) and in the *Préface*. Among his other works may be mentioned his *Origines organiques de la morale* (1870), his *Poésie homérique et l'ancienne poésie française* (1847), his various researches in positivism, and his contributions to the *Journal des Savants* and to the *Histoire littéraire de la France*. The personality of Littré is charmingly revealed in his *Etudes et glanures* (1880). He was simple of heart, high-minded, and even-tempered.

Littré, sa vie et ses travaux," in the *Nouveaux Lundis*, vol. v (Paris, 1863); Dupanloup, *Avertissement aux pères de famille*, a polemical pamphlet (ib., 1863); Louis Pasteur, *Discours de réception à l'Académie Française* (ib., 1882); Ernest Renan, *Discours en réponse à celui de Pasteur* (ib., 1882); Caro, *Littré et le positivisme* (ib., 1883); A. F. C. Saint-Hilaire, *Souvenirs personnels sur Littré* (ib., 1895); Giuseppe Carducci, *Opere*, vol. iii (Bologna, 1897).

LITTROW, lĭt′rō, JOSEPH JOHANN VON (1781–1840). An Austrian astronomer and mathematician, born at Bischofteinitz, Bohemia. He became director of the Cracow Observatory in 1807 and of the Kasan Observatory in 1810, in 1816 was made associate director of the observatory at Budapest and in 1819 was called to the University of Vienna as professor of astronomy and director of the observatory, which owes to him a thorough reorganization. His lectures were extremely popular. His published works include: *Theoretische und praktische Astronomie* (3 vols., 1821–27); *Dioptrik, oder Anleitung zur Verfertigung der Fernrohre* (1830); *Gnomonik, oder Anleitung zur Verfertigung aller Arten von Sonnenuhren* (1831; 2d ed., 1839); *Atlas des gestirnten Himmels* (1838; 4th ed., 1886); an excellent popular exposition of the principles of astronomy, entitled *Die Wunder des Himmels* (1834–36; 8th ed., 1894–97). Consult his biography in his *Vermischte Schriften* (Stuttgart, 1846).

LITTROW, KARL LUDWIG VON (1811–77). An Austrian astronomer, born at Kasan, the son of Joseph Johann von Littrow, whom he succeeded in 1842 as director of the Vienna Observatory. The publication of the meteorological records of the observatory from 1755 on was due to his efforts, and he brought the *Annalen* of the observatory to a high grade of scientific perfection. He devised a new method of reckoning longitude at sea, edited his father's works, adding largely to his *Wunder des Himmels*, and wrote a valuable *Verzeichnis der geographischen Ortsbestimmungen* (1844–46) and *Populäre Geometrie* (1839).

LITUITES, lĭt′ū-ī′tēz (Neo-Lat., from Lat. *lituus*, augur's staff). A genus of fossil tetrabranchiate cephalopods allied to *Nautilus*, found in rocks of Ordovician and Silurian age. The shell in its young stages resembles that of the primitive *Nautilus* in being closely coiled, but in its adult condition the last whorl straightens out and grows at a tangent to the coiled portion to form a long straight shell, in much the same manner as does the shell of the Cretaceous *Baculites* (q.v.). This straightening of the last whorl shows among the later species of Silurian time in much younger individuals than it does in the earlier species of Ordovician time, and thus affords an illustration of accelerated development of an acquired characteristic. Consult A. S. Hyatt, "Phylogeny of an Acquired Characteristic," in *Proceedings of the American Philosophical Society*, vol. xxxii (Philadelphia, 1894).

LITUR′GICAL MUSIC. See SACRED MUSIC.

LIT′URGY (Gk. λειτουργία, *leitourgia*, service, from λειτουργός, *leitourgos*, minister, from λεῖτος, *leitos*, public + ἔργον, *ergon*, work). A form of public worship, especially for the celebration of the Lord's Supper. The word is frequently used in the Septuagint translation of the Old Testament to denote the great public service of the Hebrews, the sacrifices of the Temple, and the work of the priests. Thence it passed into the New Testament, where it is used for any ministry, including the ministry of the worship of the Church. Its ecclesiastical use was soon limited to the public religious service and especially to the Lord's Supper, which is still called in the Greek church "the Divine Liturgy."

From the days of the Apostles there has been a form of worship connected with the Lord's Supper, reproducing in more or less detail the words and actions of the first institution of that

Sacrament by Christ. This form was influenced in some degree by the Passover ritual and also by the methods of observing the Sabbath eve in the Jewish household. The references to the liturgy in the first three centuries are not very numerous, but by a comparison of these we are led to think that in the ante-Nicene period there was a form of service very similar in all parts of the Church. Such a form appears in the early documents from which the Eighth Book of the Apostolic Constitutions was compiled.

With the conversion of Constantine a new epoch in the history of the liturgy begins. The influx of large numbers of the higher classes into the Church, the decay of the catechumenate, the building of large and magnificent places of worship, resulted in the enrichment of the service and the elaboration of the ritual.

In various parts of the Empire the development was different, and as a result we have a number of types of liturgy resembling each other in their main features, but differing in details; in all of them the service is divided into two great parts, the first devoted to instruction and consisting of the reading of Scripture, sermon, and prayers. To this part of the service all were admitted, and it received the name of *Missa Catechumenorum*, or the Mass of the Catechumens.

The second part was reserved for those who were to partake of the Sacrament and was called *Missa Fidelium*, or Mass of the Faithful; this began with the kiss of peace, then followed the offering of the bread and wine, the *Sursum Corda*, Preface, the great prayer of thanksgiving (Eucharist) including the words of institution; this was followed by the invocation of the Holy Spirit upon the elements and intercession for the living and dead. After this, the consecrated elements were distributed, with a formula, and the service ended with a prayer of thanksgiving and the dismissal of the faithful. The names *Missa Catechumenorum* and *Missa Fidelium* are of Western origin, but the Greek liturgies are divided on nearly similar lines into Proanaphora and Anaphora. The word *anaphora* is the Greek equivalent of *sursum corda* (lift up your hearts).

The two great classes of liturgies, the Eastern and the Western, may be subdivided into families. The best division of the Eastern liturgies is into national rites.

The *Syrian rite* had its centre at Antioch and is at present represented by the Greek liturgy of St. James, still used on the festival of that saint at Zante. Some account of the earlier form of this liturgy can be gathered from the earlier writings of St. Chrysostom. The Maronite church of Mount Lebanon still uses a Syriac version of this liturgy. The services in the early Church at Jerusalem as reconstructed from the writings of St. Jerome and St. Cyril, and the *Peregrinatio* of St. Silvia show a very strong resemblance to this liturgy; it is also closely related to the liturgy found in the Apostolic Constitutions and known as the Clementine liturgy.

The *Persian rite*, now used by the sect of Nestorians, is represented by the liturgy of *The Apostles Addai and Mari*. The centre of this rite is at Edessa. There is one common proanaphora, to which may be attached numerous anaphoras. The language is Syriac. Recently many of these Nestorians have joined the Orthodox Eastern church and use its liturgy.

The *Byzantine rite* is the most important of all the Eastern rites and is used throughout the world in many different languages. It is the rite of the great Russian church, of the Greek church, and of other smaller communions. There are three liturgies in this rite, that of St. John Chrysostom, that of St. Basil, and that of St. Gregory Dialogos or the Presanctified. The two latter are used only on special days, while that of St. Chrysostom is the ordinary liturgy. It is this rite which is used in the Greek churches in America. The *Armenian liturgy* is a daughter of the Byzantine, though in its present form it has been influenced by the Roman.

The *Egyptian rite*. In a manuscript recently discovered on Mount Athos and first published in 1899 we have a collection of liturgical prayers used by Bishop Serapion, a friend of St. Athanasius. It is probably not later than 350 A.D., giving us the earliest-known form of the Egyptian service, and should be compared with the more developed form in the liturgy of St. Mark, which is the typical Egyptian liturgy. The Copts still use a version of this liturgy.

In many of the Eastern communities there is a *Uniat rite*, which is a compromise between the Orthodox and the Roman forms, but usually contains the Roman Canon of the Mass.

The Western liturgies may be divided into the Latin and the Vernacular; the former represented now by the Roman Mass and the latter by the various Protestant liturgies.

The earliest references to the *Latin liturgy* of the West are found in the writings of the North African school, and it was probably in North Africa that the first Latin liturgy was used. At Milan St. Ambrose took great interest in the development of the service; as a result, we have the liturgy which bears his name and is still used in the diocese of Milan. The early Gallican liturgies were supplanted after Charlemagne by the Roman, and we know them only from such remains as have come down to us and are published in Mabillon, Mone, and others. The Christians in Spain under Arab rule used what is known as the Mozarabic liturgy, a form of which, revised by Cardinal Ximenes, is still in use in a few churches in Toledo. The Celtic or British church also had its own liturgy, which bears distinct traces of a connection with the Oriental rites. After the time of St. Augustine (597 A.D.) the older form gave way gradually to the form introduced by him, which was a modified form of the Roman. Before the Reformation there had developed in England a number of diocesan *Uses*, which, however, affected the eucharistic office but little. The most famous of these "uses" was the Sarum, which just before the Reformation was very widely used. From it was taken much of the present service of the Church of England.

The earliest extant form of the Roman liturgy, or *Mass*, is found in the "Leonine Sacramentary," probably compiled about 550 A.D. Later forms are found in the sacramentaries of Gelasius and Gregory the Great. From the eighth century on, Rome has striven to enforce uniformity in ritual and has succeeded in supplanting the various Latin uses until to-day her followers, with very few exceptions, use the same form of liturgy in all lands and all churches. See MISSAL.

The *Vernacular liturgies* of the West are the product of the Reformation. The leaders both in Germany and England tried at first to reform the Latin service, but soon abandoned it for a vernacular form. The earliest attempts were made in Germany between 1520 and 1526. In the latter year appeared Luther's German Mass, and from that time a large number of German services were compiled, some following the old Latin, while others made radical changes. The followers of Luther were inclined to be conservative, while those of Zwingli were more radical. A comparison of the Lutheran liturgies, or *Agendas,* of the sixteenth century shows a certain type of service which may be called normal, consisting of: (1) Introit; (2) Kyrie; (3) Gloria in excelsis; (4) collect; (5) epistle; (6) alleluia; (7) gospel; (8) creed; (9) sermon; (10) general prayer; (11) preface; (12) Sanctus and Hosanna; (13) exhortation to communicants; (14) Lord's Prayer and words of institution; (15) Agnus Dei; (16) distribution; (17) postcommunion thanksgiving; (18) benediction. With the rise of rationalism in the seventeenth century the older forms of liturgies gave place to a very bald, bare service, in which the congregation had no part. A revival and return to earlier forms began with the publication in 1822 of the *Kirchenagenda* for the Court and Cathedral Church of Berlin, and since that time new and revised agendas have been introduced in nearly all the German states, among the most important of which is the *Agende für die evangelische Landeskirche* introduced into Prussia in 1894.

The first agenda of the Lutheran church in America was the work of H. M. Mühlenberg in 1747. At present either "The Church Book" of 1891 or "The Common Service" of 1888 is used; but neither of these is rigidly enforced. Both of them represent a return to the earlier type of the sixteenth century.

Zwingli set forth a communion service for the Reformed church in 1525, which was to be used once a year in Holy Week. This was the liturgy used at Zurich as late as 1675. The form of liturgy recommended by Calvin is found in his *Manner of Celebrating the Lord's Supper.* After the sermon there was a long prayer, including a petition for the worthy reception of the sacrament; then followed (*a*) the Scripture lesson, 1 Cor. xi. 25–29; (*b*) an address warning all to examine themselves; (*c*) the communion, the elements given with a formula—during the reception Psalm cxxxviii is sung; the celebration closes with (*d*) the prayer of thanksgiving, (*e*) Song of Simeon, and (*f*) the blessing. The service is that now used in the Reformed church of America and was introduced in a modified form into Scotland by John Knox in his *Book of Common Order* and used until his death. This book gave great latitude for extempore prayer. Besides the office for the holy communion it contained various other services and alternate forms. In 1644 the Westminster Assembly adopted the Directory of Public Worship, in which the office for the holy communion is stripped almost entirely of its liturgical form, and room is made for the minister to use his own compositions. The communicants sit instead of kneeling at the Lord's Table. The minister reads the words of institution, then offers a prayer of blessing, and distributes the bread and wine with a formula. After all have communicated, the minister is to give solemn thanks to God.

The form of communion service used in the churches of the Anglican communion is found in the Book of Common Prayer of these churches. In character it occupies a ground between the liturgies of the Reformed and Lutheran churches on the one side and the Roman on the other. This service was first printed in 1549 and has been revised a number of times both in its English and American forms. The edition now in use in England is that of 1662; in America, that of 1892. The most marked peculiarity of the American form is due to the influence of the Scottish Nonjurors' office and consists in the addition of an Invocation of the Holy Spirit to the Prayer of Consecration. See PRAYER BOOK, COMMON.

Beginning with the Oxford movement in England in the first half of the nineteenth century, there has been a remarkable revival in the study of liturgies both in England and America, and many Christian bodies have shown an increasing tendency to introduce liturgical forms into their services.

LITUUS, lĭt′ū-ŭs. See Spiral.

LIU-CHIU ISLANDS. See Luchu Islands.

LIUDGER, lē′ụt-gẽr, Saint (c.740–809). The first Bishop of Münster in Germany. He was born in Friesland, but received his education in England, where he studied and did missionary work under Alcuin (q.v.). On his return to the Continent he sought to convert his fellow countrymen to Christianity, but in 784, at the time of Wittekind's mission to Friesland, temporarily abandoned the work and made a journey to Rome. Afterward he resumed his missionary labors and became the first Bishop of Münster. The various *Vitæ Sancti Liudgeri* have been published by Diekamp in four volumes entitled *Geschichtsquellen des Bistums Münster* (1881). For his life, consult: Hüsing (Münster, 1878); Pingsmann (Freiburg, 1879); Krimphove (Münster, 1886).

LIUDPRAND, lē′ụt-pränt, or **LIUTPRAND OF CREMONA** (c.992–c.972). An historian, to whom we owe much of our knowledge of the history of Italy in the tenth century. He came of a noble Lombard family. His father was Ambassador of King Hugo of Italy to Constantinople in 927 and died soon after. Liudprand was thereupon educated at the dissolute court of Hugo, but was early destined for the Church. Nevertheless he was throughout his life better versed in pagan learning than in Christian lore, and in his works biblical quotations are interwoven with many excerpts from Cicero, Vergil, Horace, and Ovid. After Hugo's power began to wane, Liudprand turned towards Berengar II (q.v.) and obtained a position in the new ruler's chancery. In 949 he went on an embassy to Constantinople, but soon thereafter he had a dispute with Berengar, and we do not hear of him again until 956, in which year he appeared at the court of King Otho of Germany. At the request of Bishop Recemund of Elvira, he began in 958 his best work, the *Antapodosis*. In it he attacks Berengar and his Queen, Willa, but also treats of the Italian history in the period 886 to c.952. He is not impartial, but interesting and learned. In 961 Otho the Great made him Bishop of Cremona, whence he is spoken of as Liudprand of Cremona. Throughout the Germanic invasion of Italy he played an important rôle, and in 968 he went to Constantinople to seek the hand of a Byzantine princess for the future Otho II, but the Emperor Nicephorus (q.v.) refused the proffered alliance. We have the experiences of this embassy preserved in Liudprand's *De Legatione* (Eng. trans. in Henderson's *Select Documents of the Middle Ages*, London, 1896). He died soon after his return. There is no foundation for the statement so often made that Liudprand also took part in the later successful embassy to Constantinople which obtained the hand of Theophano for Otho II. Besides the two works mentioned above, Liudprand also wrote: *De Rebus Gestis Ottonis Magni Imperatoris*, covering the period from 960 to 964. The best edition of his works is in the *Monumenta Germaniæ Historica* (Berlin, 1839) published separately (2d ed., Hanover, 1877). Consult: Köpke, *De Vita Liutprandi* (Berlin, 1842); Wattenbach, *Deutschlands Geschichtsquellen*, vol. i (7th ed., Stuttgart and Berlin, 1904); Osten-Sacken, "Aus Liudprands Werken," in *Geschichtsschreiber der deutschen Vorzeit* (2d ed., Leipzig, 1889).

LIU-KIU (lyo͞o′kyo͞o′) **ISLANDS.** See Luchu Islands.

LIUTPRAND, lē′ụt-pränt (c.690–744). A king of the Lombards (712–744), under whom they rose to their greatest power. He attacked and conquered Ravenna (728). In 739 he made an alliance with Charles Martel against the Arabs and three years later defeated the dukes of Beneventum and Spoleto. The result of his legal activity was the *Edicta Liutprandi*. Consult Hartmann, *Geschichte Italiens im Mittelalter* (3 vols., Gotha and Leipzig, 1897–1911).

LIVADIA, lē̇-vä′dē̇-ȧ. An estate of the Russian Imperial family on the south coast of the Crimea, Russia, situated about 3 miles southwest of Yalta (Map: Russia, D 6). It consists of two palaces surrounded by extensive parks and gardens. The new or Large Palace was built in 1911 from plans by Krasnov, while in the exceedingly simple Small Palace, close by, Alexander III died on Nov. 1, 1894. The adjacent Imperial estate of Oreanda contains the ruins of the palace burnt down in 1882.

LIVADIA, lĭv′ä-dē′ȧ (Lat., from Gk. *Λεβάδεια*, *Lebadeia*). A town of Greece, capital of the Nomarchy of Bœotia, situated on the western edge of the plain formed by the draining of Lake Copais. (See Bœotia.) In ancient times it was famous for the subterranean oracle of Trophonius (q.v.). Under Turkish rule it was the most important town in northern Greece. The town lies at the foot of a steep hill crowned by a ruined castle, attributed to the Catalan Grand Company (q.v.). The site of the cave of the oracle is not with certainty identified. Pop., 1909 (according to Baedeker), 6250. See Baedeker, *Greece* (4th Eng. ed., Leipzig, 1909).

LIVE-FOREVER. See Houseleek.

LIVENS, Jan. See Lievens, Jan.

LIVE OAK. A town and the county seat of Suwannee Co., Fla., 81 miles west of Jacksonville, on the Seaboard Air, the Atlantic Coast, the Florida, and the Live Oak, Perry, and Gulf railroads (Map: Florida, D 1). It is a shipping point for early vegetables for the North, and has also a considerable trade in lumber, brick, lime, limestone, cotton, corn, hay, and live stock. The town contains a public library, city hall, and the Suwannee Springs. There are municipal water works. Pop., 1900, 1659; 1910, 3450.

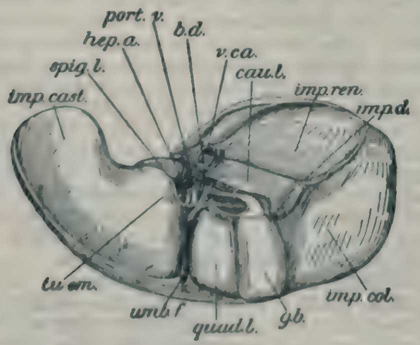
LIVE OAK. See Oak.

LIV′ER (AS, *lifer*, OHG. *libara, lebara*, Ger.

Leber; probably connected ultimately with Lat. *jecur*, Gk. *ἧπαρ, hēpar*, Armen. *leard*, Skt. *yakṛt*, liver). The largest gland in the body; it weighs from three to four pounds, and measures about 12 inches from side to side, and 6 or 7 inches from its anterior to its posterior border. It is situated in the right hypochondriac region, and reaches over to the left. It is thick and indented behind, where it crosses the convex bodies of the vertebræ; convex on its upper surface, where it lies in the concavity of the diaphragm; and concave below, where it rests against the stomach, colon, and right kidney. This lower surface presents a fissure dividing the organ into a right and a left lobe. The liver is retained in its position by five ligaments. Besides the right and left lobe, there are three smaller lobes. The great bulk of the organ is, however, made up of the right lobe, which is six times as large as the left.

The vessels of the liver are the hepatic artery, a branch of the cœliac axis (see AORTA), which supplies the organ with nutrient blood; the portal vein, which conveys to the liver the venous blood of the intestines, spleen, and stomach; the hepatic veins, which convey the blood from the liver into the inferior vena cava; the hepatic duct, which carries off the bile from the liver; and the lymphatics.

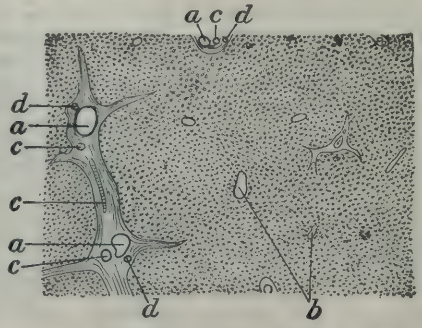
The liver, both on its surface and internally, is of a dark reddish tint. The substance of the organ is composed of lobules held together by extremely fine areolar tissue, and ramifications of the minute branches of the various hepatic vessels. Each lobule is composed of a mass of hepatic cells, of a plexus of biliary ducts, of a portal plexus (from the contents of which the cells obtain the biliary matters that are found in their interior), of a branch of the hepatic vein, and of minute arteries. The exact mode in which the bile formed in the cells makes its way into the ducts is not known. The numberless minute ducts gradually run into one another, until, as they emerge from the lower surface of the liver, they are reduced to two large trunks, which soon unite to form the hepatic duct. Into the hepatic duct, the cystic duct from the neck of the gall bladder (presently to be described) enters, and the two combine to form the common duct (*ductus communis choledochus*), which opens into the duodenum. (See DIGESTION, ORGANS AND PROCESS OF.) This common excretory duct of the liver and gall bladder is about 3 inches in length, and of the diameter of a goose quill.



INFERIOR SURFACE OF HUMAN LIVER.

Imp. cast., impressio gastrica; *spig. l.*, spigelian lobe; *hep. a.*, hepatic artery; *port. v.*, portal vein; *b. d.*, bile duct; *v. ca.*, vena cava; *cau. l.*, caudate lobe; *imp. ren.*, impressio renalis; *imp. d.*, impressio duodenalis; *imp. c.*, impressio collica; *tu. om.*, tuber omentale; *umb. f.*, umbilical fissure; *quad. l.*, quadrate lobe; *g. b.*, gall bladder.

The chemical composition of the liver in health is as follows: 68.6 per cent of water and 31.4 per cent of solid constituents—of which 3.8 are fat, 4.7 albumen, while the rest is made up of vessels, salts, and extractive matters. (In the diseased condition known as fatty degeneration of the liver, the fat is enormously increased.) Sugar, varying in amount from 1 to 2 per cent, is also found; and inosite, uric acid, sarcine, xanthine, and leucine usually occur in traces.



SECTION OF HUMAN LIVER.

Showing general arrangement of lobules: *a*, interlobular (portal) vein; *b*, intralobular (hepatic) vein; *c*, hepatic artery; *d*, bile ducts; the boundaries of the lobules are imperfectly defined by the irregular areas representing the poorly developed capsule of Glisson.

The gall bladder may be regarded as a *diverticulum* or offshoot from the hepatic duct. It has somewhat the shape of a pear, and lies in a depression on the undersurface of the liver. Its use seems to be to serve as a reservoir for the accumulation of the bile, when its flow into the intestine is interrupted, as it is always found full after a long fast, and empty when digestion is going on. That the gall bladder is not an essential appendix to the liver is shown by the fact that it is absent in many genera of mammals and that it may be removed from man without harmful effects.

Physiology. It was formerly believed that the liver served merely for the separation of the biliary secretion from the blood; but there is now abundant evidence that the organ has several other functions. The changes which take place in the liver cells result in (1) the formation of bile; (2) the production of glycogen; (3) the formation of urea. The liver also, next to the skeletal muscles, is an important source of animal heat. The formation of bile is the result of cellular activity on the part of the liver. Experiments on frogs and birds show that no bile can be formed when the liver has been extirpated. The coloring matter of the bile is derived from the blood, the substances connecting the blood and bile pigments being the following: hæmatoporphyrin, which very closely resembles bilirubin, and hæmatoidin, a substance found in old blood extravasations, which is probably identical with it. The bile is formed from the blood of the portal vein and not from that of the hepatic artery, as was formerly thought. The second function of the liver, the formation of glycogen, was discovered by Claude Bernard (q.v.) by experiments on dogs. Bernard fed a dog for seven days with food containing a large quantity of sugar and starch, and, naturally, found sugar in both the portal and hepatic blood; but when the diet was restricted to meat, Bernard still found sugar in the blood of the hepatic vein, but none in the portal vein if this were cut off so as to prevent a reflux of blood from the hepatic system. Bernard also found sugar in the substance of the liver. It was thus proved that the liver was capable of forming sugar from other substances besides carbohydrates. Bernard found later that a liver removed from the body, and from which all sugar had been completely washed away by injecting a stream of water through its blood vessels, would still contain a considerable quantity of sugar. This fact could only be explained by supposing that the liver contained a substance readily convertible into sugar, a supposition subsequently proved correct by the discovery of a starchy substance now called glycogen. Although glycogen is produced most freely under a diet of sugar or starch, it is also manufactured, though in less amount, from a proteid diet. The experiments of Pavy upon dogs showed that the average amount of glycogen in the liver of dogs fed on animal food was 7.19 per cent; when fed on food mixed with sugar, 14.5 per cent; and on a vegetable diet (potatoes, with bread and barley meal), 17.23 per cent. Another series of experiments by Pavy, on rabbits, demonstrated the dependence of the formation of glycogen on the kind of food eaten. Pavy found that in the livers of rabbits which had fasted three days glycogen was practically absent; on a diet of starch and grape sugar he found 15.4 per cent glycogen, and on a diet of cane sugar, 16.9 per cent. Glycogen is also formed to some extent on a gelatin diet. Fats do not produce it.

The present views of the glycogenic function of the liver were only arrived at after a long series of experiments and much debate. Nearly all physiologists admit that Bernard demonstrated it completely, although for a long time many apparently well-made experiments seemed to throw great doubt on the subject, some believing that the sugar found by Bernard was a product of post-mortem changes. It is a fact that it is difficult to find sugar in the liver which may not be said to be produced after death; consequently, demonstrative experiments are exceedingly difficult. On examining the blood which comes from the lungs in animals upon which vivisection has been performed it is found to contain no sugar. Other experiments have left no doubt of the fact that, to serve some purpose in the animal economy, sugar is destroyed in its passage through the lungs, the most generally received view being that it is converted into lactic acid, which unites with the alkalies in the blood to form lactates, which again are converted into carbonates. It is thought that among the causes of the disease diabetes is an abnormal performance of the function of respiration (q.v.). The glycogenic matter of the liver, in composition, reactions, and particularly in its readiness to be transformed into sugar, has considerable resemblance to starch, and is called by some authors amyloid matter. On account of its insolubility in water it may be extracted from the liver after all the sugar has been washed out. See LIVER, DISEASES OF THE.

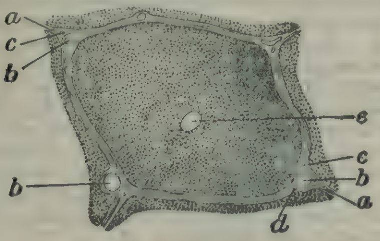
There are two main theories as to what becomes of hepatic glycogen. One is that this substance is converted into sugar during life by means of a ferment called *liver diastase*, which is also produced in the liver; and that the sugar thus formed is conveyed by the blood of the hepatic veins to the various tissues, there to undergo combustion, i.e., oxidation. The second theory is that the conversion into sugar is a post-mortem phenomenon, and that during life no sugar exists in healthy livers.

There is a considerable amount of evidence to show that some of the urea is formed by the liver, though not all of the urinary solids are produced by the hepatic cells. It is certain, however, that urea is not secreted by the kidneys, whose function is merely one of separation. Urea is derived from proteids, and there is evidence to connect its production with one, if not two, of the products of digestion of proteid substance in the alimentary canal, viz., *leucine* and *tyrosine*. These substances are believed to be the result of pancreatic digestion, and, to some extent, possibly of the action of microörganisms. The connection between leucine and tyrosine and urea is supposed to be as follows: These materials, formed during intestinal digestion, are carried by the portal vein to the liver. By the action of the hepatic cells they are converted into urea, which is then conveyed by the hepatic veins into the general circulation and in due time reaches the kidneys and is there eliminated from the body. This view is supported by the observation that the introduction of leucine into the alimentary canal increases the amount of urea in the urine, but leucine itself does not appear. Again, in acute yellow atrophy of the liver, in which rapid destruction of its cells takes place, the urea of the urine is replaced by leucine and tyrosine. Lastly, the liver is found to contain a considerable amount of urea, differing in this respect from other glands; and if blood be passed through the liver of a recently killed animal its urea content is greatly increased. The use of the bile in the digestive process is sufficiently explained in the article DIGESTION, ORGANS AND PROCESS OF.

This important gland first shows itself in the form of yellowish-brown cells in the polyps, and gradually becomes more concentrated and developed in the echinoderms, annelids, nudibranchiate gastropods, insects, crustaceans, air-breathing mollusks, cephalopods, fishes, reptiles, birds, and mammals. The physiological anatomy of the liver may be briefly stated as follows: The lobules previously mentioned are about $\frac{1}{25}$ of an inch in diameter and of an ovoid shape. They are surrounded by a plexus of blood vessels, nerves, and ramifications of the hepatic duct, comprising what are called the interlobular vessels. These are all inclosed by a sheath which is a prolongation of the proper coat of the liver (capsule of Glisson), but attached loosely by areolar tissue. This sheath follows the vessels to the subdivisions within the interlobular spaces (spaces between the lobules), but does not extend to the capillary vessels *within* the lobules. In a few animals, as the pig and polar bear, the lobular structure can be seen with the naked eye, but in man and most mammals it cannot. The lobules are intimately connected with each other, branches of the interlobular vessels being each distributed to several of the lobules. Any one lobule, however, may be considered as representing the physiological anatomy of the whole liver, and the study of its anatomy and functions will answer for the study of the whole gland. The lobules receive blood at their surfaces from the capillary terminations of the portal vein, these vessels having received the terminations of the hepatic artery before passing into the lobules. It is very important to bear in mind this peculiarity of distribution, which is often overlooked. The branches of each hepatic vein, the vessel which carries the blood from the liver to the ascending great vein (ascending vena cava), by which it is returned to the heart and lungs, have their origin *within* the lobules. Their capillary extremities arise from the capillary ramifications of the portal vein and, passing towards the centre of the lobule, converge into three or four radicles, which, uniting at the centre, form the *intralobular* veins, which are the commencement of the hepatic veins. These intralobular veins, which are in the centre of each lobule, are from $\frac{1}{1000}$ to $\frac{1}{400}$ of an inch in diameter, and they follow the long axis of the lobule, receiving vessels in their course till they empty into larger vessels situated at the base of the lobules, called by Kiernan sublobular veins. They collect the blood from all parts of the liver, and, increasing in size by union with one another, they at last form the three hepatic veins which discharge the blood from the liver into the ascending vena cava. Now, these hepatic veins are a long way from the influence of the heart's action, lying as they do between the portal circulation and the veins going to the heart; but a provision has been made to assist in the propulsion of their contents, and they are supplied with a muscular coat composed of unstriated muscular fibres. The most essential elements of the lobule, or of the liver, are the hepatic cells, which are the true secreting elements of the gland. They are minute, polygonal-shaped bodies about $\frac{1}{1000}$ of an inch in their longest and $\frac{1}{1500}$ in their shortest diameter, having one nucleus, or sometimes two nuclei, with some granular matter. (See CELL.) They are surrounded by an independent network of extremely minute vessels $\frac{1}{10,000}$ of an inch in diameter, of uniform size throughout, called the biliary capillaries, in which the bile first makes its appearance.

As the bile ducts increase in size they contain numerous follicles and cluster-like glands which are called racemose (the biliary acini of Robin), and they continue to occupy the biliary passages as far as the *ductus communis choledochus*, or the common bile duct, which empties into the intestinal canal. Those which are found in the smallest ducts are simple follicles from $\frac{1}{800}$ to $\frac{1}{400}$ of an inch in length. The larger of these glands are formed of groups of these follicles, and are from $\frac{1}{250}$ to $\frac{1}{100}$ of an inch in diameter. The nutrition of the liver is provided for by the hepatic artery, which has three sets of branches. As soon as it enters the sheath formed by the capsule of Glisson, it sends off very fine branches, called *vasa vasorum*, to the walls of the portal vein, to those of the hepatic vein, to its own branches, and an exceedingly rich and beautiful network of branches to the hepatic duct. When the hepatic artery is well injected it almost completely covers the duct with its ramifications. The hepatic duct proper, or that single vessel so called lying outside of the liver, is formed by the union of two ducts, one from the right and one from the the left lobe of the liver. It is about 1½ inches long, and joins the duct from the gall bladder, called the cystic duct, to form the common duct, or *ductus communis choledochus*, which is about 3 inches long and of the size of a goose quill, and empties, in common with the pancreatic duct, into the intestine, a little below the middle of the duodenum, or about 5 inches below the stomach. The gall bladder is an elongated, pear-shaped sac about 4 inches in length and 1 inch in breadth, having a capacity of about one and a half fluid ounces. The cystic duct, connecting it with the hepatic duct, is the smallest of the three larger ducts and is about 1 inch in length. In the gall bladder there are also numerous small racemose glands similar to those above mentioned as existing in the biliary ducts generally. They consist each of from four to eight follicles lodged in the submucous tissues. They secrete mucus mixed with bile. The idea has been entertained by some that these biliary racemose glands found in different parts of the biliary ducts were the bile-producing glands, while the hepatic cells were the organs for secreting sugar, or, in other words, for the conversion of the glycogenic matter of the liver into glucose, or grape sugar; but this view has not been found tenable. The nerves of the liver are derived from the pneumogastric, the phrenic, and from the solar plexus of the great sympathetic. They all penetrate the gland at the great transverse fissure, and follow the blood vessels in their course of distribution to the various parts of the organ, but their terminal distributions are not yet well understood. The lymphatic vessels of the liver are numerous and consist of two layers. The outer or superficial layer is situated immediately beneath the serous or peritoneal covering. The inner or deeper layer forms a plexus surrounding the lobules, having entered the liver along with the portal veins, hepatic arteries, and bile ducts, enveloped in sheaths of Glisson's capsule. In their course they invest the branches of both ducts and blood vessels with a delicate network of tubes, and on arriving at the surface of the lobules they enter them and form another remarkable network of lymphatic passages, traversing the lobule in every direction. Every blood capillary is enveloped in a lymphatic sheath in very much the same manner that the interlobular vessels are enveloped in the sheath of Glisson's capsule. These lymphatic sheaths surrounding the other vessels are otherwise called the perivascular lymphatic spaces, and are similar in structure to those which are found in various parts of the body. See LYMPHATIC.

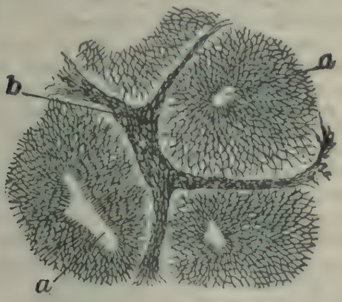
Histology. The macroscopic divisions of the liver which are known as lobes are subdivided microscopically into lobules by extensions inward of the connective tissue of Glisson's capsule. In some of the lower animals, e.g., the pig, each lobule of the liver is completely surrounded by this connective tissue. In man the amount of connective tissue is small and does not form a complete investment for each lobule. The demarcation of the lobules is, therefore, not at all sharp. The structure of a liver lobule may be described as follows: At the centre of each lobule is the central vein, which is a branch of the hepatic vein. Passing out in a radiating manner from this central vein is a dense network of capillaries in the meshes of which lie the cords of liver cells. These liver cells are polyhedral in shape, granular, and contain rather large nuclei. In the connective tissue which lies at the junction of three or more lobules is found the group of vessels known as the portal canal and consisting of the hepatic artery, the portal vein, and the bile duct. The smaller bile ducts consist of a single layer of columnar epithelium surrounded by a thin layer of connective tissue. In the larger ducts there is a well-defined mucosa consisting of a single layer of epithelium resting upon a stroma, outside of which are a few smooth muscle cells and some fibrous tissue. Usually at some distance from the portal system in the connective tissue between two adjacent lobules is the sublobular vein, a branch of the hepatic vein, into which the central veins empty.



SECTION OF LIVER OF HOG.

Showing very diagrammatically the lobules; *a*, interlobular connective tissue; *b*, *c*, branches of portal vein and hepatic artery; *d*, bile ducts; *e*, interlobular vein.

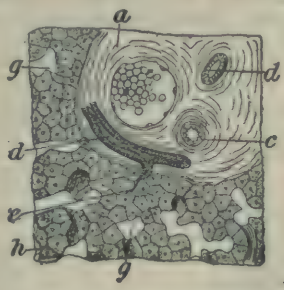
The blood supply of the liver is very large, being conveyed by two distinct systems—the portal system and the hepatic system. The portal vein and the hepatic artery enter the liver at the hilus and, entering the organ, divide and subdivide, following the extensions inward of Glisson's capsule. Upon reaching the boundary of the lobules the vessels break up into the intralobular capillary network already referred to. Distinct up to the time of entering the lobule, the blood of the two systems mingles at some point within the lobule capillaries and empties into the above-mentioned central vein, whence it finds its way into the hepatic vein. Bile capillaries extremely minute in size originate within the lobules and follow the cords of liver cells to the periphery of the lobules, where they empty into the smaller bile ducts. Lymphatics accompany the blood vessels, forming in the capsule a superficial lymphatic system, in the substance of the liver proper a deep lymphatic system. The nerves of the liver enter the organ at the hilus in company with the blood vessels and lymphatics. They are composed mainly of nonmedullated fibres, although some medullated fibres are intermingled. They branch, following the subdivisions of Glisson's capsule, and reach the periphery of the lobules. Extremely minute fibrils enter the lobules to terminate in end arborizations among the liver cells.



SECTION OF INJECTED HUMAN LIVER.

The capillaries having been filled from the central vein, *a*; *b*, branches of portal vein.

The two distinct functions, that of the production of bile and the formation of sugar, which are now generally recognized as being performed by the liver, have led some physiologists to suppose that this gland is composed of two distinct portions or anatomical elements, and Robin has adopted this theory and calls one portion of the liver a biliary organ and the other a glycogenic or sugar-forming organ. The lobules and hepatic cells, with their different vessels, he regards as performing the glycogenic function, and the little racemose glands which are attached to the biliary ducts along their course as the bile-producing organs; and others have entertained ideas of the independence of the sugar-making and bile-producing portions of the organ. But from the fact that bile is commonly found in the lobules, and that the biliary capillaries are connected with the excretory biliary ducts, the conclusion seems to be unavoidable that the bile is formed in the lobules, and, moreover, by the hepatic cells. It therefore becomes a question as to what are the functions of the little racemose glands attached to the larger bile ducts. They have much the form of mucous glands in other parts of the body, and from the examinations of Sappey, who has found the bile to be viscid in proportion to the number of these glands in the ducts containing it, they appear to be really mucous glands. In the rabbit, an animal in which these glands are not found in this situation, the bile is quite fluid, and free from its ordinary viscidity. It has generally been thought that the bile was secreted exclusively from the blood which has been brought from the intestines by the portal vein, and that, indeed, the principal office of the liver was to separate effete matter from this portion of the venous system; but many experiments which have been made since Bernard discovered the glycogenic function of the liver go to show this idea erroneous. It has also been thought that the hepatic artery may furnish material for the secretion of bile, while the portal vein furnished that for the production of sugar; but these views again are quite overthrown by many well-established facts and experiments. It has been found that, after the ligation of the hepatic artery, bile has been



SECTION OF LIVER OF DOG.

Including portion of lobule and interlobular or connective tissue, *a*; *b*, portal vein; *c*, hepatic artery; *d*, bile ducts; *e*, small peripheral bile vessel; *g*, blood channels; *h*, hepatic tissue.

secreted from blood furnished by the portal vein, and this view is now generally accepted; but the experiments of Oré, who succeeded in gradually obliterating the portal vein without immediately producing death, apparently show that bile is secreted from blood furnished by the hepatic artery. In one instance in which a patient died of dropsy the portal vein was obliterated, and yet the gall bladder was full of bile. Anomalous cases have been reported where the portal vein, instead of passing through the liver, emptied into the ascending vena cava, and where also there was found no deficiency of bile. These facts point to the conclusion that the secretory elements of the liver have an elective power, and that this gland may elaborate its products either from venous or arterial blood. The natural color of bile is variable: in the pig it is bright yellow; in the dog, dark brown; and in the ox, greenish yellow. In general, it may be stated that it is dark green in carnivorous, and greenish yellow in herbivorous, animals. Its specific gravity is variously stated. Some authorities place it at 1026; others from 1020 to 1026; and again others from 1026 to 1031. These differences are considerable, but the numbers were probably the result of exact observation, as the bile is found to differ under different circumstances. Fresh bile is nearly inodorous, but after being taken from the body of an animal it soon undergoes putrefactive changes. It has been generally thought to be invariably alkaline, and this is true of that which is found in the hepatic duct, but it often has an acid reaction after it has passed into the gall bladder.

COMPOSITION OF THE BILE ACCORDING TO ROBIN

The bile contains two classes of constituents, one of which consists of true secretions destined to reënter the system and perform certain functions. They contain, with other matters, some that are formed in the liver and are no doubt elaborated from materials furnished by the blood. These are the salts included in the accompanying table under the names of taurocholate and glycocholate of soda. Biliverdin, the coloring matter of the bile, is probably a mixture of different coloring principles which undergo rapid change on exposure to the air. It has some analogy to the coloring matter of the blood, and it is also, like the biliary salts, supposed to be formed in the liver. This coloring matter has intense power, and in cases of obstruction of the biliary passages will give the skin and conjunctivæ a decidedly yellow color. Like hæmoglobin, it contains a portion of iron, but the relative amount has never been ascertained. The other constituents of the bile are truly excretory, being composed of effete matter brought by the blood vessels from the various parts of the system. In this class is cholesterin, which has long been known as a constituent of the bile, whose chemical and physical characteristics were well recognized, but whose physiological relations were not understood. (See CHOLESTERIN.)

Greene (8th Am. ed., New York, 1914); Morris and McMurrich (eds.), *Morris's Human Anatomy* (5th ed., Philadelphia, 1914). See ALIMENTARY SYSTEM.

LIVER, DISEASES OF THE. The liver is subject to a number of disorders, circulatory, inflammatory, and infectious, some of which originate in the organ itself, while others arise from disorders in other parts of the body. It is intimately concerned with the processes of assimilation and elaboration of food, and dietary indiscretions, especially if long continued, are certain to affect the health of the organ unfavorably.

Biliousness is an unscientific and inaccurate term used to designate a condition which presents the symptoms of languor, headache, dizziness, furred tongue, a tendency to constipation, with perhaps slight yellowing of the skin, and a general sense of atony, depression, and discomfort, and which is popularly supposed to be due to derangement of the liver. The underlying pathological condition is probably an active hyperæmia of the organ. It depends not upon an excessive secretion of bile, but upon some perversion of its function or its retention in the bile ducts. Moreover, most of the symptoms do not depend directly upon changes in the bile, but upon interference with digestion in the stomach and intestines, together with the development and absorption of an infinite variety of poisonous products of decomposition, many of which are muscular poisons. Normally these are not allowed to form, owing to the presence of the bile; but when this is retained in the bile ducts, its secretion is impaired, and its composition altered, by the disorder of the liver which is a reflex result of the gastric and intestinal irritation. Biliousness is best treated by careful regulation of the diet, avoiding what are called "rich foods," sweet wines, and malt liquors. Hepatic activity is to be maintained and stimulated by vigorous outdoor exercise. Massage over the region of the liver and gymnastics which contract the abdominal muscles are useful. Drugs which have an especial action on the liver (cholagogues) are given to promote the flow of bile and to overcome the constipation. Among the more important of these are mercury in the form of blue mass and calomel, podophyllin, nitromuriatic acid, and the saline purgatives. Laxative saline mineral waters may be taken in the morning. See BILE.

Acute yellow atrophy is a remarkable disease of the liver in which the gland undergoes rapid degeneration and diminishes to two-thirds or one-half its normal size. The malady is comparatively rare and occurs after severe mental emotions, and in people whose constitutions are weakened by dissipation, by syphilis, or (in women) by pregnancy. After a period characterized by indefinite gastrointestinal symptoms, such as nausea, vomiting, and irregularity of the bowels, the characteristic features of the disease appear. These consist of jaundice and marked cerebral disturbances, viz., headache and restlessness, then delirium and gradually developing coma, with convulsive twitchings towards the end. The disease is almost invariably fatal within a few days after the severe symptoms begin.

Congestion of the liver may be active or passive. Active congestion occurs in the course of fevers and must form a part of acute inflammatory processes. Passive congestion is caused by diseases of the heart or lungs, which interfere with the return of blood through the gland. A severe form of passive congestion is known as *nutmeg liver* and results from valvular disease of the heart. The organ enlarges considerably and becomes darker in color and in advanced conditions acquires a peculiar appearance of red, yellow, and white mottling.

Inflammatory processes in the liver may be acute or chronic, and comprise perihepatitis, abscess, and cirrhosis. Perihepatitis is a gradual thickening of the capsule of the liver caused usually by chronic alcoholism, syphilis, or the chronic peritonitis that sometimes accompanies Bright's disease. In some cases the thickened capsule contracts and produces marked interference with the circulation of the organ, which assumes an almost globular form. The portal circulation in particular may be obstructed, and symptoms similar to those mentioned under cirrhosis result.

Abscess of the liver arises from the introduction into it of some septic agent through the circulation or through the bile ducts and may be multiple or single. The single or solitary abscess is common in tropical countries, often follows an attack of dysentery, and is thought to be caused by the *Amœba coli*. Solitary abscesses often reach an enormous size, and the pus may make its way into the peritoneal cavity or into the pleural cavity, where it may perforate the lung and be discharged by coughing; or it may point through the skin. These abscesses are best treated by evacuating the pus by surgical means. Multiple abscesses are usually a result of pyæmia (q.v.) and are very fatal.

Cirrhosis (*κιρρός*, yellow), or chronic interstitial hepatitis, is a slow inflammation of the liver which results in an extensive growth, usually in the course of the portal canals, of a fibrous contractile tissue which compresses and destroys the secreting cells and seriously obstructs the circulation of the blood through the portal system of veins. The disease may assume two forms: hypertrophic cirrhosis, in which the organ is greatly enlarged and its surface smooth; and atrophic cirrhosis, in which the gland is reduced often to less than half its normal size, and the surface is rough or nodular ("hobnail liver") from the irregular contraction of bands of fibrous tissue. In the great majority of cases cirrhosis is caused by the excessive use of alcohol in the form of beer, wine, or spirits. The symptoms are characteristic, especially in advanced cases. Obstructive circulatory disturbances are manifested in the stomach by nausea and vomiting, sometimes of blood; in the lower intestinal tract by hemorrhoids, and in the abdominal cavity by ascites. In this form of dropsy the effused fluid may amount to three or four gallons. Jaundice is a symptom more apt to occur in the hypertrophic than in the atrophic variety of cirrhosis. The disease is very intractable, but some patients live for years in comparative comfort with proper treatment. The taking of alcohol must be stopped entirely; the diet must be light but nutritious; and the bowels kept active. When ascites supervenes, attempts are made to promote its absorption by giving diuretic and purgative drugs; but it is often necessary to draw the fluid off repeatedly by puncturing the abdominal wall. Omentopexy (Talma's operation) consists in sewing the scarified surfaces of the omentum and peritoneum to the surface of the liver with the object of establishing a collateral circulation between the portal and septemic vessels, thus relieving the liver condition and the dropsy.

Fatty liver may be the result of an excessive deposit of fat cells in the organ, in cases of general obesity, or in emaciating diseases such as phthisis, or it may be a true degeneration in which the tissue elements are replaced by fat. The latter change takes place in acute yellow atrophy (see above) and notably in phosphorus poisoning. The liver is enlarged, smooth, its edges are rounded, and it is yellowish white on section.

Amyloid or *waxy liver* occurs in association with lardaceous disease in other organs—the brain, spleen, stomach, kidneys, and intestines. It is attributed to long-standing suppuration from phthisis, syphilis, tubercular disease of the bones or joints, and to empyema. Treatment depends upon removing the cause of suppuration. See WAXY DEGENERATION.

The liver may be the seat of tuberculosis, cancer, and syphilis. Tuberculosis occurs only as a part of a general infection. (See TUBERCULOSIS, *Liver*.) In cancer the gland becomes enlarged, hard, and nodular and irregular in outline. The disease is hopeless and treatment only palliative. Syphilis of the liver may be hereditary or acquired. In the first form it occurs as an interstitial hepatitis, in the second as a gummatous deposit during the third stage of the disease. See SYPHILIS.

Hydatid cysts are found in the liver more often than anywhere else in the body. These are caused by a minute intestinal tapeworm, *Tænia echinococcus*.

LIV'ERMORE, MARY ASHTON (RICE) (1821–1905). An American reformer. She was born in Boston and was educated in the Charlestown (Mass.) Female Seminary, remaining for three years after graduation as a teacher of Latin, French, and Italian. She subsequently married D. P. Livermore, a Universalist clergyman (who died in 1899), and assisted him for some time in editing the *New Covenant*, a Universalist paper in Chicago. She took an active part in the antislavery and temperance movements and during the Civil War distinguished herself by her labors for the soldiers under the direction of the United States Sanitary Commission. Afterward she became prominent as a lyceum lecturer upon moral and social questions and took a very conspicuous part in the total-abstinence cause and in the woman-suffrage movement. For several years she was one of the associate editors of the Boston *Woman's Journal* (1870–71). Her publications include: *The Children's Army* (1841); *A Mental Transformation* (1848); *Pen Pictures* (1863); *What Shall we Do with our Daughters?* (1883); *My Story of the War* (1888); *The Story of my Life* (1897). With Frances E. Willard, she edited *American Women.*

LIVER OF SULPHUR, VOLATILE. See BOYLE'S FUMING LIQUOR.

LIV′ERPOOL. A county borough and city of England, geographically in Lancashire, on the right bank of the Mersey estuary, 31½ miles by rail west-southwest of Manchester, and 201 miles northwest of London (Map: England, D 3). The centre of the city is about 3 miles from the sea. Liverpool is the second port in England (after London) and the third city in population (after London and Birmingham). Seven railways enter the city, and there is a daily steamship communication with Dublin. There are four tunnels under the town in connection with the London and North-Western Railway and one in connection with the Midland Railway. A tunnel under the Mersey, 1230 yards long, opened in 1886, connects Liverpool with Birkenhead (q.v.). The city covers an area of 16,642 acres and extends in a semicircular bend along the river front, which is lined for about 7 miles by docks and basins, connected by an electric-trolley railway. In the centre is the great floating landing stage. The docks constitute one of Liverpool's most striking features. The principal streets diverge from the level ground on the river bank up the adjacent slopes, which attain a maximum altitude of 250 feet. The main arteries are the Stanley and Scotland roads, while Church and Bold streets are famed for their large and handsome stores. The modern improvement of Liverpool dates from early in the nineteenth century, and some of its public buildings are among the finest in the world. St. George's Hall, built from 1838 to 1854 with the proceeds of dock profits, occupying three and one-half acres of land, is 600 feet long and 170 feet wide. It is of the Corinthian order of architecture, and its great hall, containing one of the largest organs in the world, is used for public meetings, music festivals, organ recitals, etc.; the assize courts and other public offices are in the building. Near St. George's Hall are the Free Library and Museum, the Walker Fine Art Gallery, the Picton Lecture Hall and reference library, the Lime Street railway station, and the principal theatres. Also centrally situated are the municipal offices and the New Law Courts; other fine structures include the town hall, in Corinthian style, opened in 1754, and forming one side of a quadrangle, with the Exchange in French Renaissance occupying the other sides; the extensive customhouse in Ionic, the post office, Royal Institution, the buildings of Liverpool University, the markets, banks, insurance buildings, hotels, and several places of amusement. Of the numerous ecclesiastical buildings, St. Luke's, a fine modern Gothic church, occupies a prominent site, and St. Peter's is the pro-cathedral of the diocese. St. James's Mount is the site of the cathedral, begun in 1904 and designed to be the largest in England. There are several large and elegant squares in the east or fashionable part of the town, fine parks, and suburbs studded with the handsome mansions and private residences of the merchants and tradesmen of the city. Of the numerous monuments and statues in the city, the chief are those of Queen Victoria, Prince Albert, Nelson, Wellington, and Huskisson.

For administrative purposes, the county borough and city of Liverpool is divided into 35 wards, with 103 councilors and 34 aldermen. In 1893 the title of the chief magistrate was raised from mayor to lord mayor. The Parliamentary borough of Liverpool sends nine members to Parliament. To remedy the evil of overcrowding in the poorer quarters, old tenements have been condemned and either torn down by their owners or purchased by the city. The poorest among the working people live in underground cellars, which are highly injurious to health. The city now issues strict regulations as to their minimum size, height, position with regard to the ground, ventilation, light, etc., violation of such regulations being punished by fine. How serious the evil was may be seen from the fact that with an average city death rate of about 23 per 1000 in 1896–99, the mortality in unsanitary districts during the same period ranged from 33 to 65. The death rate in the modern artisans' dwellings built by the city was only 21. Municipal dwellings were first opened in Liverpool about 1888, accommodating 271 families and 12 shops. The city has been building ever since, the buildings differing in accommodation and size according to their location for artisans and for unskilled laborers. The former are largely three-room dwellings rented for about $6 per month, the latter one- and two-room dwellings at an average monthly rent of $1 per room. The corporation owns considerable real estate, a great part of which it has inherited from the mediæval municipality.

The water supply has long been in the hands of the city. The old supply from Rivington becoming inadequate, the corporation under an act of Parliament acquired Lake Vyrnwy in Montgomeryshire, from which it conveys the water through an aqueduct 68 miles long. The work was completed in 1872. As population increased, a further supply was needed, and the Vyrnwy River, an affluent of the Severn, was impounded; this work was completed in 1892. Subsequently the Mochnant and Conwy rivers were impounded and led by tunnels to Lake Vyrnwy, the main reservoir; the work was finished in 1910. The cleansing of the city of the sewage and garbage is carried on by the corporation under the immediate supervision of the city engineer. The material gathered is converted as far as possible into fertilizers, the rest being disposed of by combustion. The clinker remaining after combustion is broken up and made into slabs for sidewalks. Part of the sewage is conveyed to the municipal sewage farms, on which are raised crops of rye, grass, and all kinds of vegetables. These farms have been thus remuneratively managed for many years. The maintenance of municipal baths dates as far back as 1794, Liverpool having been the first city in England to provide its citizens with cheap bathing facilities. It has at present the largest and best-fitted bathing establishments in England, which are patronized by more than

1,000,000 people a year, but with the extremely low prices (one cent and upward) the city has not been able to make them self-sustaining. The losses, however, are more than offset by the profits of the municipal markets.

The entire system of docks and harbor improvements of the city is in the hands of the Mersey Docks and Harbour Board, in which are represented the three boroughs Liverpool, Birkenhead, and Bootle. On the east side of the estuary the docks have a frontage of about 6½ miles, of which about 4¼ miles are in Liverpool and the remainder in the borough of Bootle. On the Cheshire side the Birkenhead docks have a frontage of over 2 miles. The Liverpool and Bootle docks and basins have a water area of 418 acres, with a lineal wharfage of 27 miles. The Birkenhead docks have a water area of 165 acres and a lineal wharfage of 9½ miles; this includes the great Float (occupying the site of Wallasey Pool), which forms a dock of 120 acres, with a wharfage of about 5 miles. On the Liverpool side there are some 60 docks and basins, and on the Cheshire side 14; in addition, Liverpool has three graving docks, and Birkenhead three. The docks can receive the largest vessels, but, owing to the great difference of the tides, can be opened for only a short time at high water. The famous landing stage is 2478 feet long and 80 feet broad, supported by about 200 floating pontoons and connected with the river wall by eight footbridges and a floating bridge, 550 feet long and 35 feet wide, for vehicles. The system of inclosed docks was begun by the Liverpool Corporation in 1709; by the Act of 1857 the management was transferred to the Mersey Docks and Harbour Board. The Birkenhead docks, begun in 1843, were acquired by Liverpool in 1855; they are now of especial importance in the grain and cattle trade and in the export trade to the Orient. The docks on both sides of the estuary are equipped with the latest and most efficient machinery and appliances and are bordered with immense warehouses. The Herculaneum Dock in Liverpool contains a remarkable petroleum magazine made of solid rock and having a capacity of 60,000 barrels. The city acquired an electric plant in 1895, which was subsequently enlarged to provide power for the municipal tramways. The latter have been worked by the city since 1897; previously the lines were leased at a profit to a private company. Liverpool owns and maintains five hospitals for infectious diseases. In addition to several large parks, there are numerous gardens, the total area of parks and gardens being 881 acres. This does not include two parks aggregating over 200 acres owned by the city but outside the city limits. The largest of the parks is Sefton, containing 269 acres and opened in 1872.

In addition to its public schools the city subsidizes a great number of institutions for technical instruction; there are special centres of instruction for working women and girls; evening classes in commercial and technical subjects; a school of applied art; and departments of electrical engineering, hygiene, and commerce in connection with the Liverpool University. The latter, incorporated in 1903, had in 1913–14 about 1100 students. Also notable are the Liverpool College, Liverpool Institute, School of Tropical Medicine, School of Art, School of Architecture and Applied Science, St. Francis Xavier's College, Catholic Institute, and the Liverpool School of Science. There is a nautical college for the training of officers and seamen for the merchant marine. The city maintains free public libraries, which are well equipped and accessible to the people. Free lectures for working people are given in connection with that department. The museums include the Derby Museum, with zoölogical, botanical, and geological departments and an aquarium; and the Mayer Museum, containing European and Oriental antiquities and an ethnographical collection.

Liverpool's foreign trade is far more important than its industrial establishments. These include engineering works, sugar refineries, tobacco manufactories, and mills for oil pressing and making oil cake. Formerly Liverpool was famous for its shipbuilding. The city has the largest share of the British trade with America, Australia, India, Africa, and the Mediterranean countries, and is next to London as a commercial port. The growth of the port is indicated in the following table of shipping entered and cleared (foreign and colonial trade):

YEAR	Vessels	Tonnage
1801	5,060	459,719
1831	12,537	1,522,436
1861	21,095	4,977,272
1881	20,249	7,893,948
1901	20,087	12,636,225
1911	....	14,767,990
1912	....	14,699,889

Leading articles of import are cotton (85 per cent of all cotton imports into the country), flour and grain, cattle, dressed meat, raw sugar, wool, tobacco, timber, leather, etc. The chief articles of export are cotton goods, iron and steel manufactures, woolen goods, machinery, pig iron, etc. Total imports and exports in 1901 were valued at £131,557,791 and £105,808,166 respectively; in 1906, £146,701,650 and £150,348,511; in 1911, £159,914,782 and £176,524,235; in 1912, £179,250,136 and £194,115,379. In 1912 exports of domestic produce amounted to £163,725,870, and of foreign and colonial produce, to £30,389,509. Liverpool is a great shipping point of emigrants to America.

The growth of Liverpool in population has kept pace with its commercial progress. In the middle of the fourteenth century there were only about 800 inhabitants. In 1700 the population was nearly 6000; in 1760, about 25,000; in 1801, 82,000; in 1851, 375,000; in 1891, 629,548; in 1901, 684,958. The latter figure is the population of an area of 13,239 acres. The area at the 1911 census is stated at 16,642 acres; the population of this area was 704,134 on the basis of the 1901 census, and 746,421 according to the 1911 census. The parliamentary borough of Liverpool comprises 9 constituencies, aggregating 8149 acres, with 626,634 inhabitants in 1901 and 623,698 in 1911.

The name Liverpool, probably Anglo-Saxon in origin, first occurs in 1190. In 1207 King John granted certain privileges to all settlers in the place, and in 1229 it received a charter of incorporation. Before 1600 its growth was insignificant. During the Civil War it was held by the Parliamentarians, was thrice besieged, and was taken by Prince Rupert in 1644. Its commercial prosperity began after the Restoration. During the eighteenth century it grew rich in the slave trade and privateering; later it became the great emporium for American trade. The first important steam railroad in the world was opened between Liverpool and Manchester in 1830.

LIVERPOOL. The capital of Queen's Co., Nova Scotia, Canada, and port of entry at the mouth of the Mersey River, 112 miles southwest of Halifax by rail (80 miles direct), on the Halifax and Southwestern Railway (Map: Nova Scotia, E 4). It contains the county buildings, has a good harbor, considerable shipbuilding, and a good trade in lumber and fish. It has tanneries, leather manufactures, saw and planing mills, iron foundries, granite works, pulp and paper mills, and a carriage factory. The United States is represented by a consular agent. Pop., 1901, 1937; 1911, 2109.

LIVERPOOL, Charles Jenkinson, first Earl of (1727–1808). An English statesman. He was born at Winchester, April 26, 1727, and came of a distinguished Oxfordshire family. He was educated at the Charterhouse School, London, and at University College, Oxford, graduating M.A. in 1752. In early life he published, among other works, a *Discourse on the Conduct of Government Respecting Neutral Nations*—a valuable work, which was translated into several languages. His literary ability attracted the notice of Lord Bute, whose private secretary he became. In 1761 he entered Parliament for Cockermouth, and the same year he was appointed an Undersecretary of State. Having become the leader of the King's supporters in the House of Commons, he was made Joint Secretary of the Treasury in 1763 and a Lord of the Admiralty in 1766. In 1772 he was appointed one of the vice treasurers of Ireland and in 1776 Master of the Mint. He was Secretary of War (1778–82), and his connection with the closing years of the American War gained him an unpopularity on both sides of the Atlantic, which, however, he outlived. In 1783 he was appointed by Pitt a member of the Board of Trade. In 1786 he was made Chancellor of the Duchy of Lancaster, created Baron Hawkesbury, and appointed President of the Board of Trade; in 1796 he was created Earl of Liverpool. After this he withdrew almost entirely from public life, published an able *Treatise on the Coins of the Realm* in 1805, and died in London, Dec. 17, 1808.

LIVERPOOL, Robert Banks Jenkinson, second Earl of (1770–1828). An English statesman. He was the eldest son of Charles Jenkinson. Educated at the Charterhouse School and Christ Church College, Oxford, he went in 1789 on a Continental tour, which gave him a sight of the opening days of the French Revolution. In 1790 he was elected to Parliament from Appleby and became closely connected with the Tory interests. After seven years' work as a member of the India Board, he became Foreign Secretary in Addington's cabinet in 1801, negotiating while in that position the famous Treaty of Amiens with Napoleon. After 1796 he was known by courtesy as Lord Hawkesbury and in 1803 was created Baron Hawkesbury. On the return of Pitt to power Hawkesbury became Home Secretary (1804–06). He held the same office under the Portland administration in 1807. In 1808, on the death of his father, he became Earl of Liverpool. After holding portfolios in the ministry of Perceval, he became Premier on the assassination of that statesman in 1812 and for 15 years remained at the head of English affairs. Though his administration was frequently very unpopular, he was enabled, by the union in 1812 of the old and new Tories, to obtain majorities. His ministry was criticized for the bad administration of finances, the increase of the duty on imported grain, and the reputed connivance of England in the putting down of the revolution in Naples. Liverpool was not a brilliant man, but his conservatism and steadiness helped materially to carry England safely through the enormous difficulties of the Napoleonic era and the rearrangement of affairs which became necessary thereafter. Consult: *Memoirs of the Public Life and Administration of the . . . Earl of Liverpool* (London, 1827); C. D. Yonge, *Life and Administration of Robert Banks, Second Earl of Liverpool* (ib., 1868); T. E. Kebbell, *History of Toryism* (ib., 1882).

LIVERPOOL, University of. Founded in 1881 as University College, Liverpool, it constituted a part of Victoria University from 1884 to 1903, when it was completely reorganized and given the rank of an independent university. It consists of five faculties—arts, science, engineering, law, and medicine. The university has made great progress since the reorganization and has developed in particular on the arts side. There have been introduced departments of Celtic paleography; diplomatics; social anthropology and ethnology; archæology; civic design, town planning, etc.; local history and records. The school of social science and of training for social work was unique until recently. The medical faculty has acquired a reputation through its school of tropical medicine. A strong department for university extension is conducted by the university. The number of students in 1912–13 was 1312. See Manchester, University of.

LIVER ROT, or Fluke Disease. A disease of sheep, due to the presence, in the liver and biliary ducts, of a flat worm (*Fasciola hepatica*), or fluke, which often causes very heavy losses in sheep-raising countries. It also occasionally attacks rabbits, hares, deer, and cattle. Autumn and early winter are the periods of its most frequent occurrence. Close, damp weather, inducing a rapid growth of soft, luxuriant herbage, favors its development; low, damp, marshy situations, water meadows, and undrained lands furnish a large proportion of cases, and sheep grazed upon such land, or taking a single draft from an infected, stagnant pool, may contract the disorder by swallowing the young flukes. The hay from such localities induces rot almost as readily as the fresh grass. From 15 to 40 days usually elapse before any serious consequences follow from the presence of the parasite. At first, indeed, digestion appears to be stimulated, and the sheep thrive rather better than before; but by and by they rapidly waste, their wool becomes dry and easily detached, their bowels irregular, their skin and mucous membranes yellow, as is usually conveniently observed by examining the eye and its pearly caruncle. The body, after death, is soft, flaccid, and indifferently nourished; watery effusions are discovered underneath the jaws and in other dependent parts; the small quantities of unabsorbed fat are dirty yellow; the liver is soft and enlarged and usually mottled with patches of congestion. In the thick and muddy bile the flukes, with their myriads of spawn, float in variable numbers.

The treatment of liver rot is so seldom satisfactory that if the animals, when first affected, are in tolerable condition, no time should be lost in having them slaughtered. If remedial measures are attempted, the sheep should be removed to a dry situation and liberally supplied with dry, nutritive food. During the summer feed grain with the grass; during the winter, when cases are most frequent, supply clover hay, peas, or split beans, a little bruised linseed cake, and a few roots; pieces of rock salt should also be laid about the ground for the patients to lick. Medicines are seldom of much avail. Those most to be relied on are turpentine and powdered gentian in two-dram doses, given daily, beaten up with an egg and a little milk or with some linseed gruel. The turpentine, besides acting beneficially as a stimulant, doubtless also exercises a poisonous action on the flukes, while the gentian imparts tone to the irritated and relaxed bowels. The prevention of liver rot is usually effected by removing from the land all superfluous moisture by deep and thorough drainage. Where pastures are suspected of infestation, beans and oats should for a time be fed in moderate quantity, and access allowed to rock salt. The reason for avoiding inundated or marshy localities is that the immature form of the liver fluke, after passing its preliminary stages in the bodies of water snails, attaches itself to grass and other plants in such places and thus gains entrance to the sheep along with the forage. See FLUKE; TREMATODA.

LIVERSEDGE, lĭv′ẽr-sĕj. A town in the West Riding of Yorkshire, England, 6 miles southeast of Halifax and 1 mile west of Heckmondsville. Its importance is due to its manufactures of iron, mill machinery, woolen, cotton, chemicals, and other goods. Pop., 1901, 13,980; 1911, 14,658.

LIVER SPOTS. See CHLOASMA.

LIV′ERWORT. The common name given to the representatives of one of the two great groups of Bryophytes (q.v.). See HEPATICÆ.

LIV′ERY (AF. *liverie*, *liveree*, OF. *liveree*, *livree*, Fr. *livrée*, from ML. *liberata*, delivery, from Lat. *liberare*, to deliver, set free, from *liber*, free). A word applied in its origin to the custom which prevailed under Carolingian kings of delivering habits to the members of their households on great festivals. In the days of chivalry the wearing of livery was not, as now, confined to the domestic servants. The duke's son as page to the prince wore the prince's livery, and the son of the esquire wore the livery of the knight. Cavaliers wore the livery of their mistresses. There was also a large class of armed retainers in livery attached to many of the more powerful nobles. In England this custom became such a menace to strong government that in 1390 the statute of Livery and Maintenance was passed, forbidding any one save the King to give a suit of livery. The law, however, was evaded, and the evil continued until the time of the Tudors. The livery colors of a family are taken from their armorial bearings, being generally the tincture of the field and that of the principal charge; or, where the field has two tinctures, both are taken. The royal family of England have sometimes adopted colors varying from the tinctures of the arms. The Plantagenets had scarlet and white; the house of York, murrey and blue; white and blue were adopted by the house of Lancaster; white and green by the Tudors; yellow and red by the Stuarts and by William III; and scarlet and blue by the house of Hanover. An indispensable part of the livery in former times was the badge (q.v.).

The freemen of the different trade guilds of London are called liverymen, entitled to wear the livery of their respective companies, and the companies pride themselves on the splendid appearance which their liveries make in the civic train.

LIVERY COMPANIES. See GUILD; LIVERY.

LIVERY OF SEISIN, sē′zĭn (delivery of possession). In English law, the method by which the feoffment, or ceremonial conveyance of land, was effected. It was anciently requisite in all conveyances of freehold estates, as these, being founded on an actual seisin, could not be transferred otherwise than by a transfer of the seisin. In its original and characteristic form it was an open and notorious transaction, occurring on the land, the seller, in the presence of witnesses, handing to the buyer a twig or a clod of earth, in token of the land to be conveyed. This was known as a "livery in deed." When it was not feasible to go upon the land, the same ceremony might be performed at a convenient place in view of the premises to be conveyed. Such livery, known as "livery in law," was equally valid as that performed on the land itself; but the feoffment or conveyance in that case was not complete unless the vendee entered upon the premises within the lifetime of the vendor. As livery was concerned with the transfer of the seisin, it had to do only with real property described as corporeal and not with incorporeal interests, such as easements, remainders, and the like, which could be created or transferred only by the form of deed known as a grant. The former were, accordingly, said to "lie in livery," the latter to "lie in grant." The supreme importance of seisin, as the root, if not the very substance, of title, gave a unique importance to a method of conveying lands which involved an actual transfer of the seisin. Accordingly livery of seisin had the extraordinary effect of vesting in the feoffee the estate which the feoffor purported to "create" by the transaction, even though his own possession was based upon an inferior title. Thus, a life tenant or even a leaseholder, if in possession, might, by this method of conveyance, vest in his feoffee an estate greater than his own, as a fee tail or fee simple, the conveyance operating to disseise the feoffor's landlord (reversioner) or remainderman. Because of its efficacy in thus creating an estate by wrong, livery of seisin was known as a tortious method of conveyance.

Livery of seisin no longer exists as a method of conveying real property, having everywhere been superseded by deeds of conveyance. See Conveyance; Deed; Delivery; Feoffment; Seisin.

LIVERY STABLE. An establishment where horses are kept for hire and where stabling is provided. The business of keeping a livery stable is not a public calling, like that of a farrier or innkeeper, and the keeper is not, therefore, required by law to accept the custom of any and every one who may offer his trade. On the other hand, he has at common law no lien on the horse in his custody for his charges, though in the United States such a lien has generally been accorded him by statute. Placing a horse in the custody of a livery-stable keeper constitutes an ordinary bailment, the keeper having an independent possession which he may vindicate by action of trespass against any one interfering therewith. He is liable to the owner only for negligence, i.e., for failure to exercise ordinary and reasonable care. See Bailment; Agistment; Lien.

In the United States the practice of livery-stable keepers of letting out horses of their own for hire has caused the term "livery stable" to be commonly applied to establishments carrying on this business, either in conjunction with the occupation of keeping the horses of others for hire or as an independent trade. In this case the situation of the parties is reversed—the liveryman being the bailor, and the hirer the bailee, with the right of possession and the liability for injuries resulting from negligence resting upon the latter. A person hiring a horse is held to the strict performance of his contract and is bound to use reasonable care and skill in managing and caring for him. For willful abuse of the animal or for an unauthorized use, he is liable in an action of trover as for a conversion. See Hiring; Conversion.

LIV′IA DRUSIL′LA (c.56 B.C.–29 A.D.). The wife of the Roman Emperor Augustus. She was the daughter of L. Livius Drusus Claudianus. She was married to Ti. Claudius Nero, by whom she had two sons, Tiberius (afterward Emperor) and Nero Drusus. (See Drusus, 3.) But before the birth of the latter Augustus fell in love with her, divorced his own wife, Scribonia, and compelled Livia's husband to divorce her, and married her in 38 B.C. She was in many ways a remarkable woman, and her influence over the Emperor was great. She possessed strength of character and consummate tact and strove to please the Emperor in every way. The only source of discord was the question of succession to the throne, for Livia was ambitious for her son Tiberius, and her intrigues in his behalf rendered the later years of Augustus unhappy. Scandal attached to her name, and the suspicion was roused that the death of the Emperor's grandsons, Gaius and Lucius, the logical heirs, was brought about by the contrivance of Livia. Augustus, left without male descendants, was forced to adopt Tiberius in his will. He died in 14 A.D., leaving the request that Livia be adopted into his *gens* and be called Julia Augusta. Tiberius now became Emperor, but Livia continued to act as his guardian even in state matters, being unwilling to lose the power and influence she had gained. This proved excessively distasteful to Tiberius, who conceived a growing dislike for her, and, when she died at an advanced age in 29 A.D., made no concealment of his satisfaction at her death. Consult "Livius, 10," in Friedrich Lübker, *Reallexikon des klassischen Altertums*, vol. ii (8th ed., Leipzig, 1914).

LIVII, lĭv′ĭ-ī. A Roman *gens* (q.v.), of plebeian rank but great influence and power. The earliest consul from the *gens Livia* was Marcus Livius Denter, consul in 302 B.C. The later history of the family is closely bound up with the history of the Empire. (See Livia Drusilla; Drusus.) The cognomina (see Cognomen) of the *gens* are Denter, Drusus, Libo, Macatus, and Salinator. The last of these was first given to Marcus Livius, who imposed a tax on salt in his censorship. As consul with Æmilius Paulus in 219 B.C., he shared in the triumph after the Illyrian War, but was condemned for having unfairly divided the spoils. But he was consul again in 207, and in that year commanded, jointly with the consul Gaius Claudius Nero, his political opponent, the army which defeated Hasdrubal at the Metaurus. (See Hasdrubal, 3.) In 205 he was proconsul in Etruria and penned up the Carthaginian Mago in Liguria; he was censor in the following year, with Nero, his old enemy and colleague, in the consulate, and the two quarreled bitterly.

A Livius Drusus in 54 B.C. was defended by Cicero from the charge of betraying a case he was to prosecute and was acquitted. He may possibly have been the Livius Drusus Claudianus, father of Livia Drusilla and originally of the Claudian Gens, who sided with the liberators (Brutus, Cassius, etc.) and committed suicide after Philippi (42 B.C.). See "Livius," in Friedrich Lübker, *Reallexikon des klassischen Altertums*, vol. ii (8th ed., Leipzig, 1914).

LIVING FISH. A name in China, translating "lang ya," for various walking fishes (see Walking Fish), so called because they are "carried about in tubs and sold in pieces cut from the fish when alive."

LIV′INGSTON. A seaport of Guatemala, situated at the mouth of the Dulce, on the Gulf of Amatique (Map: Central America, C 3). It is a port of transit for the town of Izabal (q.v.), situated at the head of Lake Izabal, of which the Dulce is the outlet, the river not being navigable for large vessels. The town exports coffee, cabinet woods, and tropical fruits, especially bananas, the trade being chiefly with the United States. It is the seat of a United States consular agent. Pop., 2000.

LIVINGSTON. A city and the county seat of Park Co., Mont., 123 miles southeast of Helena, on the Yellowstone River, and on the Northern Pacific Railroad and its National Park branch (Map: Montana, F 4). It is a railroad division headquarters, and, besides extensive machine shops, roundhouses, etc., has lumber mills and lime works, and an important trade in live stock, wool, gold, coal, and coke. The city is of note also as a centre for sportsmen, the adjacent region affording good hunting and fishing. Among the features of the place are the Northern Pacific Railroad depot, Carnegie library, fine Federal building, and county high school. Pop., 1900, 2778; 1910, 5359.

LIVINGSTON, BURTON EDWARD (1875–). An American plant physiologist, born at Grand Rapids, Mich. He was educated at the University of Michigan (B.S., 1898) and at the University of Chicago (Ph.D., 1902), where he was fellow and assistant between 1899 and 1905. In 1905–06 he served as soil expert for the United States Bureau of Soils and for the next three years was engaged in botanical research at the Carnegie Institution, Washington. He became professor of plant physiology in 1909 and director of the laboratory of plant physiology in 1913 at Johns Hopkins University. He published *Rôle of Diffusion and Osmotic Pressure in Plants* (1903) and contributed to the NEW INTERNATIONAL ENCYCLOPÆDIA.

LIVINGSTON, EDWARD (1764–1836). An American jurist and statesman, born May 26, 1764, at Clermont, Columbia Co., N. Y. He graduated in 1781 at Princeton, studied law at Albany and New York, was admitted to the bar in 1785, and rose rapidly to high rank in his profession. From 1795 to 1801 he was a member of Congress, where he supported the measures of the Republican party and attracted attention, particularly by speeches against the Alien and Sedition Laws, on the resolution calling for the correspondence relative to the Jay Treaty, and on the conduct of President John Adams in the case of Jonathan Robbins. In 1801 he was appointed United States Attorney for the district of New York, and during the same year was elected mayor of the city of New York. Through the dishonesty of a clerk in the district attorney's office, Livingston's affairs soon became seriously embarrassed, with the result that he was found to be considerably behind in his accounts. Upon discovering the conduct of his agent Livingston voluntarily confessed judgment for $100,000, resigned his office, and prepared to leave New York. The exact amount of the shortage was something over $43,000. It was not until 1826 that a final settlement with the United States was made. The amount of the shortage with the accrued interest had then reached $100,000, every dollar of which Livingston paid. His resolution to abandon the State was unshaken, and he could not be persuaded to reconsider his decision. In December, 1803, he sailed for New Orleans, and early in 1804 became a member of the bar there. Louisiana had just been acquired by the United States, chiefly through the diplomacy of his brother, Robert R. Livingston, and a great future seemed to await men of Livingston's talents in that country. The legal system of Louisiana was a strange mixture of Spanish and French law, having its foundation in the *Corpus Juris Civilis* of the Romans. In spite of this difficulty he soon had a lucrative practice, and, by accepting land for his fees, acquired the basis of a respectable fortune. During the second war with Great Britain he was active in rousing the population of New Orleans to resistance and served for a time as secretary and confidential adviser to General Jackson. In 1820 he was elected to the Lower House of the Louisiana Legislature, and with two other members was commissioned to prepare a civil code for the State. Their draft, largely the work of Livingston, was adopted, in large part, by the Legislature in 1825. In the year 1821 he was selected by joint ballot of the Legislature to revise the entire system of criminal law of the State. For this task he possessed preëminent qualifications, having studied with great care the legal systems of Rome, France, Spain, and Great Britain. After about three years of labor he had finished a complete system of penal law, divided into codes, books, chapters, sections, and articles. Unfortunately, just as the final draft of the code was completed, it accidentally caught fire and was completely destroyed. Undaunted by this misfortune, he again began the work, and within two years it was again completed. The code was marked by liberal and enlightened principles and contained provisions looking towards a more humane penal system. The work was styled *A System of Penal Law,* and was divided into a Code of Crimes and Punishments, a Code of Procedure, a Code of Evidence, and a Code of Reform and Prison Discipline, besides a Book of Definition. The system which Livingston prepared was never directly adopted as a whole by the State, but its publication gave him fame throughout America and Europe, and many of its principles were incorporated in the legal systems of other States of America, and even in those of certain European countries, while the Government of Guatemala adopted his Code of Reform and Prison Discipline without change. In connection with this code Sir Henry Maine characterized Livingston as "the first legal genius of modern times." In 1822, while still engaged in the revision of the Louisiana legal system, Livingston was elected to Congress. He was twice reëlected, serving until 1829, when he was transferred to the United States Senate, where he took high rank. In 1831 President Jackson appointed him Secretary of State. In this capacity he prepared a number of state papers for the President, the best known being the antinullification proclamation of Dec. 10, 1832. In 1833 the President sent him as Minister Plenipotentiary to France to demand the payment by the French government of an indemnity of a million sterling on account of depredations upon American commerce. He was entirely successful in this mission and returned to the United States in 1835, settling on his estate, Montgomery Place, on the Hudson, where he died the following year. His works on *Criminal Jurisprudence,* in two volumes, were published in New York in 1873. Consult C. H. Hunt, *Life of Edward Livingston* (New York, 1864), and Carleton Hunt, *Life and Services of Edward Livingston* (New Orleans, 1903).

LIVINGSTON, HENRY BROCKHOLST (1757–1823). An American soldier and jurist, son of William Livingston. He was born in New York City and graduated at Princeton in 1774. Upon the breaking out of the Revolutionary War he entered the Patriot army, served as an aid on Benedict Arnold's staff, with the rank of major, in the operations against Burgoyne, and later received the rank of lieutenant colonel. In 1779 he went to Spain as secretary to John Jay, his brother-in-law, and was taken prisoner on the return voyage in 1782 by the British, but was soon released. He then studied law under Peter Yates, was admitted to the bar in 1783, and quickly became prominent in his profession. In 1802 he was made a judge of the New York Supreme Court and in 1807 associate justice of the United States Supreme Court, which latter office he held until his death. He is generally known merely as Brockholst Livingston.

LIVINGSTON, LUTHER SAMUEL (1865–1914). An American bibliographer. He was born at Grand Rapids, Mich., and for a time was employed in a bookstore there. Later he was connected with the rare book department of Dodd, Mead, and Company, New York City. In 1910 he formed with Robert H. Dodd the firm of Dodd and Livingston, but retired from the partnership in 1913 on account of ill health. He died at Cambridge, Mass. In 1903 he edited reprints with prefatory notes of the original editions of Milton's *Comus*, Hariot's *Virginia*, and Brereton's *Virginia*. In 1912 he printed some hitherto unpublished poems of Robert Louis Stevenson, and in 1914 compiled *Franklin and his Press at Passy* (France). He also edited from 1895 until 1914 the annual *American Book Prices Current: A Record of Books, Manuscripts, and Autographs Sold at Auction*, and from 1905 *Auction Prices of Books;* and he prepared bibliographies of first editions of Tennyson (1901), Charles and Mary Lamb (1903), Longfellow (1908), Lowell (1914), Kipling, etc.

LIVINGSTON, Peter van Brugh (1710–92). An American merchant, born in Albany, N. Y., the son of Philip, second Lord of Livingston Manor. He graduated at Yale in 1731, settled in New York City, where he became a wealthy merchant in partnership with his brother-in-law, William Alexander (Lord Stirling), and built a large mansion on what is now Hanover Square. He was a leading Presbyterian and was one of the founders in 1746 of the College of New Jersey, at Elizabethtown, N. J., which afterward became Princeton College. For many years previous to the Revolution he was a member of the New York Provincial Council. During the larger part of the period between 1759 and 1774 he was active in the Revolutionary cause, quietly but effectively promoting resistance to the mother country. In 1759 he was a member of the Council of Ten, and he was also a member of the Committee of One Hundred. In 1760 he joined the Sons of Liberty, and he became one of the leading spirits of that organization. On April 22, 1774, he was one of a party who, disguised as Mohawks, like their Boston compatriots, threw overboard a cargo of tea brought by the *Nancy* into the harbor of New York. He was President of the First Provincial Congress of New York (1775) and a delegate to the Second (1775–76). He enjoyed the friendship of Washington, and on more than one occasion was consulted by him. It was at his country place at Dobbs Ferry that General Washington, Governor Clinton, and Sir Guy Carleton met to settle matters connected with the evacuation of New York City by the British forces. After the adoption of the new State Constitution in 1777 he was elected to the Legislature and was chosen President of the Lower House. From 1776 to 1778 he was Treasurer of the Continental Congress.

LIVINGSTON, Philip (1716–78). A signer of the Declaration of Independence and a brother of Peter van Brugh Livingston. He was born in Albany, N. Y., and, graduating at Yale in 1737, became a successful merchant in New York City. There he was a member of the City Council, served in the Colonial Assembly in 1759–69, and was Speaker in 1768. An ardent supporter of the Patriot cause, he was a delegate to the Stamp Act Congress (1765), represented New York in the Continental Congress in 1774–78, was a member of the New York State Senate in 1777–78, and signed the Declaration of Independence. Livingston helped to found the New York Chamber of Commerce and was a benefactor of Yale and of King's (later Columbia) College.

LIVINGSTON, Robert (1654–1725). An American colonist, the founder of the Livingston family in America. He was born at Ancrum, Scotland, the son of John Livingston, a Scottish Presbyterian clergyman, who was banished and settled in Rotterdam, Holland, in 1663. There Robert was educated by his father, after whose death he emigrated to Charlestown, Mass., about 1673. Beginning in 1686, he was awarded grants to Livingston Manor, including the major part of what are now Dutchess and Columbia counties, bordering on the Hudson River, in New York. The royal charter confirming these grants conveyed the privileges of court leet, court baron, and advowson. In 1675 he removed to Albany, N. Y., where he was appointed Secretary of the Board of Indian Commissioners. He also served as town clerk and as a member of the Colonial Assembly (1711–15, 1716–17) and its Speaker (1718–25). In 1701 he proposed a plan for grouping the English Colonies in America into "three distinct governments" for administrative purposes. Consult Livingston, *The Livingstons of Livingston Manor* (New York, 1910). See Livingston Manor.

LIVINGSTON, Robert R. (1746–1813). An American jurist and statesman, brother of Edward Livingston. He was born in the city of New York, Nov. 27, 1746, graduated at King's (now Columbia) College in 1765, studied law, was admitted to the bar in 1773, and for a time was associated in the practice of his profession with John Jay. In the same year in which he was admitted to the bar he was appointed by the crown to the position of recorder of the city of New York, a judicial office which he was compelled to relinquish two years later on account of his avowed sympathy with the Patriot party. In the following year he became a member of the Continental Congress and served on the committee appointed to draw up the Declaration of Independence, which document, however, he did not sign, owing to his withdrawal from Congress to attend the meeting of the Provincial Convention of New York. Later in the Revolution he served another term in the Congress (1779–81). He was a member of the committee which drafted the constitution of the State of New York in 1777, and upon its adoption became the First Chancellor of the State, an office which he filled with distinction until 1801. It was in this capacity that he administered the oath of office to Washington on the occasion of his first inauguration to the presidency, in New York City. While serving as Chancellor of New York, he was appointed Secretary of the new Department of Foreign Affairs, created by Congress in 1781—a position which he held until 1783, when he was succeeded by John Jay. He was President of the New York Convention of 1788, which was called to take action with regard to the Federal Constitution, and used his influence to secure the ratification of that instrument. In 1794 President Washington tendered him the post of Minister to France, which he declined; but in 1801, upon receiving a second tender of the same office, he accepted, and began the negotiations for the purchase of Louisiana, which, with the assistance of Monroe, were carried to a successful conclusion. He was associated with Fulton in the application of steam to navigation; gave much attention to the practice of scientific agriculture, publishing an *Essay on Agriculture* (1809) and an *Essay on Sheep* (1809); introduced the merino breed of sheep into western New York and was instrumental in introducing the use of gypsum as a fertilizer. He served on a commission to adjust the boundary of New York State and for a time was president of the American Academy of the Fine Arts, of which he was one of the principal founders. Consult Frederic De-Peyster, *Biographical Sketch of Robert R. Livingston* (New York, 1876), and J. L. Delafield, *Chancellor Robert R. Livingston of New York and his Family* (Albany, 1911).

LIVINGSTON, William (1723–90). An American lawyer and patriot, Governor of New Jersey from 1776 to 1790. He was born at Albany, N. Y., the son of Philip, the second Lord of Livingston Manor. He graduated at Yale in 1741 and studied law in New York City, where he was admitted to practice in 1748, and where in a few years he became one of the leading lawyers. In 1760 he purchased a large estate at Elizabethtown, N. J., where he built a mansion, which he named Liberty Hall. He was known as "the Presbyterian lawyer" and ardently opposed the institution of Episcopal dioceses in America in the *Independent Reflector,* a weekly paper which he established in 1752. He was president of the Moot, a famous law club in New York, and was a frequent contributor to the *American Whig* and the author of numerous able pamphlets defending the rights of the Colonies. In 1772 he gave up most of his law practice and retired to his New Jersey estate. With the exception of three terms in the New York Provincial Legislature as representative of his brother Philip's manor, he had no public office until his election to the Continental Congress in 1774. At first much opposed to the idea of separation from the mother country, he became convinced at last that that was the only possible course and championed it with enthusiasm. He was reëlected to the Second and Third Congresses, and in June, 1776, was made commander in chief of the New Jersey militia. In August, 1776, he was elected Governor of New Jersey, and, resigning his military command, remained in office until his death. Throughout the war his services were of the greatest value to Washington and the American cause, and he ranks as one of the most efficient of the "war governors" of the Revolution. He was a member of the convention which drew up the Constitution of 1787 and signed that document. With William Smith, Jr., he prepared a *Digest of the Laws of New York, 1691–1762.* Consult Theodore Sedgwick, Jr., *Life and Letters of William Livingston* (New York, 1833).

LIVINGSTONE, lĭv′ĭng-ston, David (1813–73). A famous missionary and explorer, born at Blantyre in Lanarkshire, Scotland, March 19, 1813. At the age of 10 he began work in a cotton factory and spent some 10 years as an operator, educating himself by private study and attending an evening school. In this manner he gained some knowledge of Latin and Greek and finally, after pursuing a course in medicine at Anderson College, Glasgow, and listening to the theological lectures of Dr. Wardlaw, professor of theology to the Scottish Independents, he offered his services to the London Missionary Society, by whom he was ordained as a medical missionary in 1840 and sent to South Africa, where he commenced his labors among the natives of Bechuanaland and the vast regions to the north. He secured the friendship and coöperation of the native chiefs, planted posts far beyond the civilized frontier, and systematically studied the languages and customs of the natives in order to establish a method of utilizing their efforts for their own civilization. In 1849 he pushed northward far beyond the Tropic of Capricorn and on August 1 discovered Lake Ngami. Continuing his explorations the following year, with his wife and children, he discovered the Zambezi River and reached Cape Town in April, 1852. After exploring the upper course of the Zambezi he struck out westward and in 1854 reached Loanda on the Atlantic Ocean. He then made his way back to the Zambezi and achieved the traverse of the continent by following that stream to its mouth in the Indian Ocean, which he reached in 1856. On this journey he discovered the Victoria Falls, the grandest cataract in the Old World. From Quilimane he sailed, in the beginning of 1856, for England, where he was overwhelmed with honors. In 1857 Livingstone published his *Missionary Travels and Researches in South Africa.* In the same year he severed his connection with the London Missionary Society and in 1858 was appointed British Consul at Quilimane for the East Coast of Africa and also commander of an expedition to explore East and Central Africa. He ascended the Shire, the lowermost of the large affluents of the Zambezi, and discovered Lake Shirwa and Lake Nyassa (Sept. 16, 1859). A narrative of the discoveries, *The Zambesi and its Tributaries,* was published during a visit paid to England in 1864–65. In the latter part of 1865 Livingstone returned to Africa to organize an expedition to discover the true source of the Nile and to labor for the suppression of African slavery. Early in 1866 he started for the interior by way of the Rovuma, and nothing was heard of him for two years. Livingstone's problem was, then, to determine whether the Zambezi joined the Nile or was a tributary of the Congo. At the beginning of 1867 he came to the Chambezi, a stream traversing in a southwesterly direction the region south of Lake Tanganyika, the end of which great body of water he reached in April, 1867. In his endeavors to penetrate farther into the continent he was continually thwarted by inundations, by the hostility of the slave dealers—both native and Arab—and by the want of supplies, which were constantly delayed and plundered. He nevertheless pressed on, discovered the Luapula (1867) and Lakes Mweru and Bangweolo. He arrived at Ujiji on Lake Tanganyika in 1869, where he remained for some time before setting out on an extended exploration of the region to the west of the northern part of that lake. In 1871 he stood on the shores of the Congo at Nyangwe, but his previous explorations had not covered the ground sufficiently to admit of his being assured that the stream before him must be the Congo. Returning to Ujiji amid great privations and sufferings, he was (Nov. 10, 1871) met by a relief party, under H. M. Stanley, sent out by James Gordon Bennett, of the New York *Herald.* Livingstone renewed his stock of medicines and supplies, and, after exploring the northern end of Lake Tanganyika with Stanley, he parted from him in March, 1872, and proceeded to continue his explorations in the Luapula-Lualaba basin, hoping to solve the Nile-Congo problem. The great explorer was exhausted by continued hardship and privation and died on May 1, 1873, at the village of Tshitambo, a friendly chief, on the shore of Lake Bangweolo. His native followers cut out his heart and buried it at the foot of the tree beneath whose branches he died, cutting a rough inscription on the trunk to mark the spot. In 1898 Mr. Sharpe, the British administrator for this district, visited the spot and observed that the tree was rapidly decaying. He raised a subscription in England and procured a substantial stone monument, which now marks the spot. The section of the tree containing the inscription was cut out and sent to the rooms of the Royal Geographical Society in London, where it is preserved. The body was taken to England, and on April 18, 1874, was buried in Westminster Abbey.

Livingstone's work in exploration is marked by rare precision and by a breadth of observation which will forever make it a monument to the name of one of the most intrepid travelers of the nineteenth century. His activity embraced the field of the geographer, naturalist, and benefactor of mankind, and it can justly be said that his labors were the first to lift the veil from the "Dark Continent."

Bibliography. Besides the works above mentioned by Livingstone, there was published, in 1874, *The Last Journals of David Livingstone, from 1865 to his Death*, edited by Horace Waller (London). For other accounts, consult: *Journal and Proceedings of the Royal Geographical Society*, vols. xx, xxii, xxiv–xxvii, xxxi, xxxiii, xxxiv, xxxvii, xxxviii (London, 1850–75); W. G. Stanley, *Autobiography*, edited by Dorothy Stanley (Boston, 1911); id., *How I Found Livingstone* (New York, 1913); A. Z. Fraser, *Livingstone and Newstead* (London, 1913); Alexander Galt, "Livingstone Centenary Exhibition at the Royal Scottish Museum," in *Scottish Geographical Magazine*, vol. xxix (Edinburgh, 1913); C. S. Horne, *David Livingstone* (New York, 1913); Harry Johnston, "David Livingstone: A Review of his Work as Explorer and Man of Science," in *Scottish Geographical Magazine*, vol. xxix (Edinburgh, 1913).

LIVINGSTONE RIVER. A name applied to the Congo River (q.v.).

LIVINGSTON MANOR. A tract of land in New York State, east of the Hudson River, and occupying the northern part of the present Dutchess County, acquired by Robert Livingston about 1674. The title was confirmed by patent by Governor Hunter in 1715, at which time the tract was computed to cover 160,240 acres. In 1752 the third proprietor, Robert Livingston, was disturbed by the encroachments of Massachusetts and complained to Governor Clinton, after which the settlement of the State boundaries secured the quiet possession of the manor until 1795. In that year efforts were made by the tenants to have the title declared invalid, and in 1844 the tenants petitioned the Legislature to set aside the grant. Both attempts were unsuccessful, but were accompanied by so much disturbance that the owners, to avoid annoyance, gradually permitted the greater part of the lands to be acquired by individual holders. Consult "Papers Relating to the Manor of Livingston" in the *Documentary History of the State of New York*, vol. iii (Albany, 1850).

LIV'IUS AN'DRONI'CUS. The pioneer in Roman dramatic and epic poetry. (See LATIN LITERATURE.) He was a Greek by birth, who was brought to Rome as a prisoner of war from Tarentum, after the close of the war waged by the Tarentines, aided by Pyrrhus, against Rome. He lived about 290–205 B.C. At Rome he became a slave of a Livius, who afterward freed him; from him Andronicus derived his name (*nomen*, q.v.) *Livius*. He learned Latin and became a teacher and author. He translated the *Odyssey* into Latin Saturnian verse and wrote tragedies, comedies, and hymns after Greek models. Mere fragments are extant, of which a collection may be found in Düntzer, *Livii Andronici Fragmenta Collecta et Illustrata* (Berlin, 1835); Baehrens, *Fragmenta Poetarum Romanorum* (Leipzig, 1886); Ribbeck, *Scœnicæ Romanorum Poesis Fragmenta* (ib., 3d ed., 1897–98); Wordsworth, *Fragments and Specimens of Early Latin* (Oxford, 1874); C. Zander, *Versus Italici Antiqui* (Lund, 1890). Though not in any sense a great writer, Livius deserves more credit than is usually accorded to him; it took no slight courage to attempt to reproduce Greek works in the crude Latin of his time. (See LATIN LANGUAGE.) Even such limited success as he achieved proves that his abilities were far from small. Consult: Martin Schanz, *Geschichte der römischen Litteratur*, vol. i (3d ed., Munich, 1907); J. W. Duff, *A Literary History of Rome* (New York, 1909); Friedrich Leo, *Geschichte der römischen Literatur*, vol. i (Leipzig, 1913).

LIVIUS DRUSUS, lĭv'ĭ-ŭs dro͞o'sŭs. See DRUSUS.

LIVNY, lyĕv'nĭ. The capital of a district of Livny, in the Government of Orel, Russia, situated on the Sosna, 95 miles southeast of Orel (Map: Russia, E 4). It has a Realgymnasium, two libraries, and a municipal bank. Its chief products are leather, tallow, soap, flour, and tobacco. Grain is the principal article of trade. Livny was founded in 1586. Pop., 1897, 20,600; 1912, 23,700.

LIVONIA, lĭ-vŏ'nĭ-ȧ (Ger. *Livland*). A government of western Russia, the middle one of the three "Baltic provinces" (q.v.), bounded by the Government of Esthonia on the north, St. Petersburg (between which and Livonia is Lake Peipus), Pskov, and Vitebsk on the east, Courland on the south, and the Gulf of Riga and the Baltic on the west (Map: Russia, C 3). Area, 17,574 square miles, of which the islands of Oesel, Mohn, Runö, etc., occupy 1096 square miles. The portion of Livonia west of the Virtz-yärvi (*yärvi*, lake) along the Gulf of Riga is flat and rather low. The eastern part of the province is mainly hilly and reaches in its highest point, Munna Mäggi (which also is the highest point of the Baltic provinces), an altitude of 1060 feet. This part of Livonia is noted for its picturesqueness. It abounds in lakes and is traversed by numerous rivers, the most prominent of which are the Aa, the Düna (which marks part of the southern boundary), the Pernau, and the Embach. There are more than 600 lakes in Livonia, of which Virtz-yärvi (106 square miles) is the largest; about one-tenth of the country consists of marsh and peat bog, and it is estimated that over one-fourth of the area is under forest. The climate is rather severe, raw, and foggy. Agriculture and stock raising are the leading industries, but the agricultural conditions in Livonia differ greatly from those prevailing in other parts of Russia. The feudal system introduced by the German conquerors practically came to an end in 1819 when the serfs of the province were emancipated by the Russian government but not endowed with land (as was subsequently the case in the rest of Russia), for the land was granted in perpetuity to its ex-feudal possessors. As a result of this arrangement, the larger part of the agricultural land of the province is in large estates owned by the nobility; the remainder is divided between the state, Church, and the smaller landholders. The large estates are worked by the most modern methods; excellent stock is raised on a large scale for both slaughtering and dairying; the dairy products are exported to a considerable extent. The principal crops are rye, barley, oats, flax, and potatoes. The manufactures are trimmed lumber, wagons, rubber articles, oil, paper, iron products, chemicals, tobacco products, etc. The centre of industrial activity is Riga (q.v.), the capital and chief port. The population, estimated at about 622,000 in 1816, was returned at 1,299,365 by the census of 1897. As calculated for the beginning of 1912 it had increased to 1,479,700. Of the inhabitants in 1897, 43.4 per cent were Letts, 39.9 per cent Esthonians, 7.6 per cent Germans, 5.4 per cent Russians, 2 per cent Jews, and 1.2 per cent Poles. Protestants (Lutheran) constituted 79.8 per cent, Orthodox 14.3 per cent, and Roman Catholics 2.3 per cent. The population of the cities is made up largely of Germans, with some Russians and Jews. Dorpat (Yuriev) is the seat of a famous university. Livonia was conquered by the Teutonic Knights and the Knights Swordbearers in the thirteenth century. When the power of the Knights Swordbearers was broken by the onslaughts of the Russians, their grand master ceded Livonia to Lithuania (q.v.). Early in the seventeenth century Gustavus Adolphus of Sweden overran and conquered the country, but it was not until 1660 that it was definitively relinquished by Poland in the Peace of Oliva. At the beginning of the eighteenth century Peter the Great of Russia wrested Livonia from Sweden, which formally renounced its possession in 1721. In recent times the Russian government has been pursuing a relentless course of Russification in Livonia. Consult: Eduard Winkelmann, *Bibliotheca Livoniæ Historica* (2d ed., Berlin, 1878), and Ernst Seraphim, *Geschichte von Livland* (Gotha, 1906).

LIVORNO, lē-vôr′nō. The Italian name for Leghorn (q.v.).

LI′VRE, *Fr. pron.* lē′vr′ (OF., pound). The name of an ancient French coin. There were livres of different values, the most important being the *livre tournois* (of Tours), which was considered the standard, and the *livre parisis* (of Paris), which was equal to a livre tournois and one-fourth. In 1795 the livre was superseded by the franc (80 francs = 81 livres tournois.—LIVRE was also the ancient unit of weight, the earliest recorded being the *livre esterlin* of Charlemagne and amounting to 5666¼ grains, or 367.128 grams. It was reputed to be based on an Arab standard, a yusdruma, sent to Charlemagne by the caliph Al Mamun. Later the *livre poids de marc* of 16 ounces was derived from this standard of Charlemagne by King John the Good. There was also a *livre de Troyes*, or troy pound. The ancient livre, equal to 489.50585 grams, persisted in France until the development of the metric system (q.v.), when the kilogram supplanted it.

LIVS, or **LIVO′NIANS**. A Finnish tribe, formerly living in Esthonia and north Livonia, now nearly extinct, holding only a narrow strip of forest land along the Baltic at the north point of Courland. They were supplanted by the Letts (q.v.). They are classed with the Baltic Finns and probably number less than 2000. Their language has nearly disappeared and the people speak a Lettish patois.

LIVY, lĭv′ĭ (59 B.C.–17 A.D.). The great Roman historian, Titus Livius, is without a history, for we have no ancient biography of him, and very little information about him is obtained either from his own writings or from allusions in other authors. He was born at Patavium (Padua), the chief city of Venetia, in 59 B.C. (a date given in St. Jerome's *Chronicle of Eusebius*), consequently at the beginning of the most important period of Roman history, for Cæsar had just obtained the government of Gaul. The place and period of his birth had great influence upon his career. Padua was a city of considerable importance, with a traditional history going back to Antenor, and Livy, a Paduan at heart, felt deep sympathy with the municipalities which preserved the old independent spirit of Italy; nevertheless he was in a larger sense a Roman and recognized the advantage of association with a people who had conquered the early enemies of his native town, and who were his fellow citizens, the Paduans having long possessed the Roman franchise. On the evidence of some inscriptions (*Corpus Inscriptionum Latinarum*, v, 2865, 2975) and of the general aristocratic spirit of his writings there is reason to believe that he belonged to a noble family; the fact that he was able to devote all his time at Rome to writing proves, further, that he had ample means. He undoubtedly received thorough training in philosophy, rhetoric, and literature, and was well versed in the Greek language and Greek literature.

When Cæsar was slain and Cicero gave voice to his Philippics, Livy was 15 years of age. He was familiar, then, with the great struggle for liberty, and with all the events of that stirring time, and in consequence was a republican. He came to Rome about 31 B.C., the year of the battle of Actium, and there he resided until shortly before his death. Although he formed a friendship with Augustus (whom, however, he mentions only twice, once to give a date and once to prove a fact), he admired Brutus and Cassius, nevertheless, and dared to say that it was a question whether or not Cæsar had been of service to his country. Augustus called him a Pompeian, perhaps in a spirit of pleasantry, as the purpose and aim of the historian must have been satisfactory to him; for while Livy idealized the Republic, he was entirely satisfied with the existing Imperial government.

Suetonius (*Claudius*, 41) remarks that Livy advised the future Emperor Claudius to write history, and that Caligula (*Caligula*, 34) called him a verbose and negligent historian. Caligula's accusation was undoubtedly due to Livy's evident ignorance of military detail and of Roman law, which resulted in errors in his description of wars and of constitutional changes. He, however, had a great reputation in his own day, of which he himself was cognizant; for he is said to have declared that he had obtained sufficient glory, but continued writing because he should miss the employment. Pliny the Younger, *Epistles*, ii, 3, tells a pleasing tale of a Spaniard who came all the way from Gades (Cadiz) to see Livy, and having seen him went home content. After the accession of Tiberius, Livy returned to Padua, where he died in 17 A.D. In the letters of Seneca (100, 9) there is a reference to dialogues, half philosophical and half rhetorical, by Livy, and Quintilian (x, 1, 39) and Seneca the Elder mention a letter addressed to his son, in which he urged him to study the speeches of Demosthenes and Cicero; but these have disappeared. His history of Rome was begun early in his life, for in book i, 19, we have a reference to the fact that the temple of Janus had been shut twice since the time of Numa—once after the First Punic War, and again after the battle of Actium; the third closing occurred in 25 B.C., so that the writing of the first book must fall between 29 and 25 B.C., and as Livy also uses here the title Augustus, which was conferred in January, 27 B.C., we may place the date about 26 B.C. In ix, 18, there is no reference to the recovery by Augustus of Crassus's standards in a passage where such reference would have been natural had Livy been writing the ninth book as late as 20 B.C. There is also evidence that the work did not appear as a whole, but in sections which contained a varying number of books. Certain passages are clearly prefaces to new parts of the history, e.g., at the beginning of books vi, xxi, and xxxi. It is noticeable that book v ends with the burning of Rome by the Gauls, so that book vi begins a new epoch; also book xvi begins the First Punic War, and book xxi the Second Punic War. These facts have led to a theory of a publication by decades or semi-decades, but it is doubtful if Livy held to this arrangement, for in the best manuscripts we find that books cix–cxvi are treated in one periocha, or summary, under the title *Bellum Civile*.

The division into decades is first mentioned about the close of the fifth century and is probably the work of copyists. The entire work consisted of 142 books, of which 35 are extant, the first (to 293 B.C.), third, fourth, and half of the fifth decade (218–217 B.C.). We have a few fragments obtained from such writers as Servius, Valerius Maximus, and St. Augustine, and a page or so from book xci, preserved in a Vatican palimpsest; this fragment was discovered in 1772. We have also from some unknown authors epitomes, *periochæ* or *argumenta*, of all the books except cxxxvi and cxxxvii. Some fragments of an epitome previously unknown were discovered by Grenfell and Hunt at Oxyrhynchus: for these, see *Oxyrhynchus Papyri*, iv (London, 1904); Kornemann, *Die neue-Livius-Epitome aus Oxyrhynchus* (Leipzig, 1904), an edition with commentary; C. H. Moore, "The Oxyrhynchus Epitome of Livy in Relation to Obsequens and Cassiodorus," in *American Journal of Philology*, vol. xxv (New York, 1904). The epitomes show that the last year recorded was 9 B.C., and this seems to indicate that Livy did not finish his history, as the event of that year, the death of Drusus, was not of sufficient importance to form the conclusion of a great work. The title of the work was probably *Ab Urbe Condita Libri*, as this is given in the best manuscripts and by the grammarians, but it is true that Livy began with Æneas, and also that he speaks loosely of his *Annales* (43, 13, 2). In his preface, however, he declares that he wrote from the beginning of the city, and Pliny, in his preface to the *Natural History*, repeats this statement. Again, the term *annales* is general in its application, and, if Livy had used it as a title, Servius, who discussed the word in its relation to *historiæ*, would have referred to the fact.

To appreciate Livy's greatness we must consider the character of the writings of his predecessors in this field, for, with the exception of Sallust, Roman historians before Livy were narrators of facts and recorders of events, mere annalists. (See ANNALS.) Livy, following the methods of his predecessors, built upon the foundation laid by them, and used with entire freedom, and evidently without a suspicion of plagiarism, the work of earlier historians. He relied largely upon the great Greek historian Polybius (q.v.); judging from the fragments of the latter's account of the Macedonian wars, we may say that Livy took his information directly, omitting Greek references and polemical notes, and supplementing what could not be readily understood by the Romans. In the account of the Second Punic War he probably used Polybius, although the Roman annalist Cælius Antipater was his leading authority for this period. Livy speaks very coldly of Polybius, and in fact not at all until book xxx, although he had used his work through the third decade. He relied upon Valerius Antias in the first decade, but later on condemned him for his exaggerations and unreliability. Livy also used many other writers, such as Quadrigarius, Calpurnius Piso, and Silenus, a Greek who wrote in a pro-Carthaginian spirit.

When Livy's authorities disagreed, he did not seek to sift their statements, as a contemporary modern historian would, but followed his own fancy or struck an average, or followed the most popular current account. Sometimes he stands for the view represented by the majority of the authorities, or for the earliest and most probable account, or, influenced by his sympathies, recognizes the pro-Roman or most picturesque or impressive views, aiming all the time at the effective story. That he had no desire to tell the truth, as Macaulay declared, is itself most untrue: see some sound remarks in Henry Nettleship, *Lectures and Essays: Second Series*, pp. 18–19 (Oxford, 1895), and M. H. Morgan, *Addresses and Essays*, pp. 13–18 (New York, 1910). Livy was by nature, beyond question, candid and truth-loving. His history is not of value as a critical work, falling below that of Polybius in this respect; but when we consider his patriotism and the charm of his style, we can understand Niebuhr's declaration that his history is a "colossal masterpiece." He was the national historian just as Vergil was the national poet. Livy accomplished the purpose of a great historian, although in not being an investigator he lacked a quality which Taine has declared to be requisite for an historian. In his celebrated preface he makes clear that he purposes to tell the story of the Roman people, and to tell it more effectively than it had been told before, with the aim of impressing his readers with the lessons to be drawn from the history of Rome in its progress to its culmination, and of drawing his own eyes away from the evils of his time. He declares that what happened before the foundation of the city he would neither indorse nor condemn. Thus, Livy may not have believed in Æneas or Romulus or Numa, but he did not think it his part to examine into the matter critically, for he intended to write not a critical but an ethical history of Rome. It is in his style that Livy stands preeminent. Although he is the great prose writer of the Augustan age, he does not follow the rhetorical style of Cicero, but, influenced by the diction of Vergil, he invented a new style, based on that of Cicero, but expanded and made mobile by the use of poetic words and phrases. He may be termed the first writer of Silver Latinity. It may be that this peculiarity in language and style brought upon him the charge of *Patavinitas*—from *Patavium* (Padua), Livy's birthplace—made by Asinius Pollio, and mentioned by Quintilian, 1, 5, 56, and 8, 1, 3, who, however, does not make clear what this charge implied. It may refer to his general style or to his use of provincialisms or to his free and enthusiastic way of speaking, at variance perhaps with the dignified restraint of Rome. Consult: Wiedmann, *De Patavinitate Livii* (Görlitz, 1848–54); Moritz Haupt, *Opuscula*, vol. ii (Leipzig, 1876); G. L. Hendrickson, "A Witticism of Asinius Pollio," in *American Journal of Philology*, vol. xxxvi (Baltimore, 1915). On Livy's style in general, consult the "Einleitung" to the edition by Weissenborn and Müller (Berlin, 1885); Henry Nettleship, *Lectures and Essays: Second Series*, pp. 108–110 (Oxford, 1895); Norden, *Die Antike Kunstprosa* (new ed., Leipzig, 1909).

In his early books he shows the influence of the subject matter upon his style, e.g., in his use of various archaisms, but when he reaches the account of the Second Punic War, and gives a description, e.g., of the visit of the Roman embassy to Carthage, and when he describes the Macedonian wars, he writes in a most brilliant and masterly way. His speeches are, perhaps, artistically the most perfect parts of his writings. They are given with no intention of reproducing the words of the speaker, but reflect the character of the individual, and describe his position and motives, as understood by Livy.

Bibliography. The *editio princeps* of Livy appeared at Rome in 1469, but books xxxiii and xl–xlv are omitted. The first critical edition is that of Gronovius (Leyden, 1645). Some of the great editions are by Drakenborch (7 vols., Amsterdam, 1738–46), by Bekker and Raschig (Berlin, 1829); by Madvig and Ussing (Copenhagen, 1861 et seq. and 1886 et seq.), a critical edition; by Luchs, a fine critical edition of books xxvi–xxx (Berlin, 1879) and of books xxi–xxv (ib., 1888). The most important modern edition, with notes, is that by Weissenborn and Müller (ib., 1858, et seq.). The various parts have been repeatedly reëdited. There are a number of good editions of separate portions: Book i by Seeley (Oxford, 1876); ii and iii by Stephenson (London, 1886); iv by Stephenson (ib., 1890); v by Whibley (ib., 1890) and by Prenderville (ib., 1890, first edition); v–vii by Cluer and Matheson (ib., 1881); vii and viii by Luterbacher (Leipzig, 1889–90); xxi–xxii by Capes (London, 1883) and by Lord (Boston, 1891); i, xxi, and xxii by Westcott (ib., 1891) and Lease (Boston, 1905, 1914); xxi–xxv by A. Harcourt (Paris, 1886); xxvi–xxx by Riemann (ib., 1889); i, xxi, xxii by Greenough and Peck (Boston, 1900). Selections from various books have been edited by Dennison (New York, 1908) and Egbert (ib., 1913). On the language and style consult, besides the works named in the body of this article, Riemann, *Etudes sur la langue et la grammaire de Tite Live* (Paris, 1884). A lexicon to Livy was begun by Fügner, but was discontinued when eight parts, carrying the work through *bustum*, had been published (Leipzig, 1889–97).

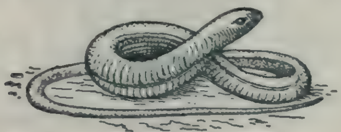
Translations.—The entire work is translated into Elizabethan English by Philemon Holland (London, 1600); books xxi–xxv are translated by Church and Brodribb (2d ed., London, 1890); the entire work is translated into German by Klaiber and Teuffel (2d ed., Stuttgart, 1854–56).

For further bibliographical aids, and for a general discussion of Livy, consult W. S. Teuffel, *Geschichte der römischen Literatur*, vol. ii (6th ed., Leipzig, 1910), and Martin Schanz, *Geschichte der römischen Litteratur*, vol. ii, part i (3d ed., Munich, 1911).

LIXIVIATION, lĭk-sĭv'ĭ-ā'shŭn (from Lat. *lixivium*, lye, from *lix*, ashes, lye). The extraction of the soluble ingredients of solid substances by allowing dissolving liquids to percolate through them. In metallurgy, lixiviation processes date from early times and were largely used on silver and copper ores. In lixiviating silver ores the silver is first transformed into a chloride and then leached or dissolved with a solution of hyposulphite of soda. With copper ores, such as those of the Rio Tinto Mines in Spain, the copper sulphide is transformed into a sulphate and dissolved by leaching with water. Recently extensive investigations have been conducted by many mining companies to discover a commercial method of lixiviating copper carbonate ores and copper ores containing other minerals. These investigations have been successful and a few large lixiviating plants were being installed in 1914. A well-known use of lixiviation is the separation of the carbonates of sodium and potassium from the ashes of wood.

LIZA, lē'sȧ. See MULLET.

LIZ'ARD (OF. *lezard, lisard*, Fr. *lézard*, Sp. Portug. *lagarto*, It. *lacerta*, lizard, from Lat. *lacertus, lacerta*, lizard). A reptile of the order Lacertilia or Autosauria, characterized structurally by the fact that the halves of the lower jaws are connected by symphysis, i.e., fused solidly together in front, while those of serpents are connected by an elastic band; and by the fact that the teeth are fixed. The vertebræ are procœlous (except in most of the geckos), and have intercentra, especially in the tail. The caudal vertebræ of most forms have a transverse septum of cartilage, forming a line of weakness—the point where the tail breaks off, as frequently happens. The ribs of the trunk articulate by their capitula only, the reduced tubercula being connected with the vertebræ by ligaments. In some groups the poststernal ribs meet in the median abdominal line, forming bony loops; in the flying dragons the ribs support winglike expansion. Most lizards are provided with fully developed limbs and five-toed feet; but the feet are modified in the chameleons (q.v.), and in some degraded forms, as the glass snake and especially the amphisbæna (q.v.), which burrow, not only have the limbs been lost externally, but in some cases the pelvic and pectoral girdles have completely disappeared, accompanied by an elongation of the body, so that these lizards are serpent-like in form and habits. The skull is modified principally in the composition of the temporal arches; the quadrate bone is movable except in the degraded families. The hyoid apparatus, extended into the tongue, is always present and well developed. In the Old World lizards the teeth are planted along the top of the ridge of the jaw (acrodont), while in the New World species they are fastened to the inner side of the ridge (pleurodont). In one American genus (*Teius*) the teeth of the young are pleurodont, but in the adult they become acrodont. The tongue is variously developed, but is always furnished with many tactile or with gustatory corpuscles. When the tongue is very long and narrow it is generally forked, and in such cases, e.g., in the monitors, it is used almost entirely as a sensory organ. In most lizards it assists in catching the food, and in some families is an elaborate instrument. Salivary glands are wholly labial, and in a single genus (*Heloderma*) become poison sacs. The digestive organs present little peculiarity, except in the cloaca, which is much modified in correlation with the strange copulatory apparatus, consisting of paired organs external to the cloaca, each a tube of erectile tissue, which can be everted like the finger of a glove. When at rest and withdrawn the organs form slight conical longitudinal swellings on either side of the root of the tail. Only one organ is inserted at a time. Most lizards lay eggs, in some cases having a hard shell, but more often a parchment-like covering. The embryos are usually much advanced before the extrusion of the egg, and some species, as the American horned toads, are practically viviparous. The embryos within the hard-shelled eggs have an egg tooth or hard point upon the end of the snout, to assist them in breaking out. Certain mysterious organs beneath the ventral skin, largely composed of fat, and hence called fat bodies (consult Butler, *Proceedings of the Zoölogical Society of London*, 1889), seem to be related to the sexual functions. Lizards (except degraded subterraneous forms) have good ears and eyes, the latter with movable eyelids (except in geckos) and a nictitating membrane; but desert-dwelling and other unusual forms have special adaptations elsewhere spoken of, e.g., under Chameleon. Binocular vision, of course, does not occur here, any more than in other animals whose eyes look sidewise.



GLASS-SNAKE LIZARD.

Externally, lizards assume a great variety of shapes, from the toadlike proportions of the moloch to the vermiform aspect of an amphisbæna; but usually the head is shapely, the neck apparent, and the tail long and distinct. The tail, indeed, is of much importance in many cases as a whiplike weapon, or as a means of safety by the ease with which it breaks off when seized, thereby giving the animal a chance to escape. By some species it is voluntarily thrown off in such an emergency, enabling the lizard to run to a refuge while the surprised foe is occupied with the cast-off and wriggling tail. Such lizards have the power of regenerating a tail, or rather a substitute for one, since the new tail contains in place of real vertebræ only a nonsegmented rod or tube of fibrocartilage. In most of the higher lizards the muscles, skins, and scales are reproduced, but among a variety of lower forms the scaling is abnormal, and is sometimes a reversion to an ancestral form. Consult Boulenger, *Proceedings of the Zoölogical Society of London*, 1888, page 351; and id., 1891, page 466. See Regeneration.

The skin of lizards, like that of snakes, is normally covered with scales, the thin, horny coating of which is shed periodically; but the amphisbænas have nearly lost all scales, and the glass snake (*Anguis*) sheds its skin in one piece. In many cases, however, the scales are not typical, but appear as little tubercles (osteoderms), such as are seen in the geckos and Gila monster, so that the whole skin looks granular or pebbled; or these dermal ossifications may be confined to the scales or shields of the head, as in the Lacertidæ. The skin is entirely devoid of glands, although certain minute excretory organs lie under the cutis of the thighs. Lizards vary greatly in color; the numerous desert-dwelling forms are, as a rule, of dull hue, and capable of little change, while forms dwelling in forests or grassy places are often highly colored, and have great power of metachrosis, as is familiar in chameleons. The chromatophores, according to Gadow, are embedded in the deeper layers of the cutis, and send out movable contractile processes, in which their pigmental protoplasm is conveyed towards or away from the surface. Black, red, yellow, and white, with their combinations of gray and brown, are the usual colors. The white pigment is made up of guanin salts. Blue and green are structural colors which are not traceable to pigment. (For the method of service of these voluntary color changes in adaptation to surroundings, see Metachrosis.) In addition to protective coloration some lizards are defended by horns and spines, which sometimes cover the entire body, as in the horned toads and the moloch (qq.v.), and sometimes grow only upon certain parts, most frequently the tail. Others have defensive or menacing appendages and corresponding habits, such as are manifested by the frilled lizards, the basilisk, the iguana, and others that make themselves look terrifying, when in fact, like all the rest (except *Heloderma*), they are harmless.

Lizards are found in all the warmer regions of the earth; their northern limit is about the annual isotherm of 50° F. (See Map under Distribution of Animals.) They are most numerous in tropical and warm countries; none occur in polar lands. In temperate regions they pass the winter in a state of torpidity, concealed under earth and débris or in hollow trees.

1. AFRICAN TYPES OF CHAMELEON.
2. FLYING DRAGON (Draco volans).
3. AUSTRALIAN MOLOCH (Moloch horridus).
4. FRILLED LIZARD, with frill expanded.
5. FRILLED LIZARD, with frill folded.
6. AUSTRALIAN SKINK (Trachysaurus rugosus).
7. EUROPEAN AGAMA (Agama stellio).
8. EGYPTIAN MONITOR (Varanus Niloticus).

Many are restricted to deserts, and have acquired interesting adaptations for resisting the blowing sand and otherwise withstanding the hardships of a hot and barren habitat. Other families are arboreal, or dwell among rocks. One species (of the Galapagos Islands) is marine, and several African and Oriental lizards are more or less completely aquatic. Most of these swift and agile reptiles are insectivorous, but some are carnivorous or even cannibalistic, and certain sluggish forms, as the iguanas, are herbivorous, and their flesh is palatable and nutritious for human use. The eating of noxious grubs and insects is a valuable service by lizards to man; and these little animals furnish food for a great variety of other reptiles, birds, and beasts of prey.

Classification. The lizards are regarded by recent authorities as one of two sections (the other being the snakes) of an order of reptiles usually called Squamata. Dr. Gadow in a review of the matter (1900) regards the lizards as an order (Autosauri, or Lacertilia), divisible into three sections:

1. *Geckones* (vertebræ amphicœlous) contains the family Geckonidæ, comprising the geckos proper (Geckoninæ), the Eublapharinæ, and the Uroplatinæ. See GECKO.
2. *Lacertæ* (vertebræ procœlous) contains the ordinary lizards—agamas, iguanas, African zonurids, glass snakes, heloderms, monitors, South American tejids, typical Old World lizards (Lacertidæ), skinks, and several small families including the degraded amphisbænas and snakelike aniellids of California and the pygopodes of Australia.
3. *Chamæleontes*—a single family with 50 or 60 species. See CHAMELEON.

Fossil Lizards. Fossil remains of lizards of the suborder Lacertilia are not well known. A few have been found in the Cretaceous and Tertiary rocks of Europe and North America, and the largest known lizard is a fossil species (*Varanus priscus*) from the Pleistocene beds of Queensland, Australia, which had a length from nose to tip of tail of about 30 feet. Many other fossil forms of lizard-like reptiles are not closely related to the Lacertilia of modern times. Such are the great sea serpents, Ichthyosaurus, Plesiosaurus, Mosasaurus, etc., of Mesozoic ages; the amphibious Rhynchocephalians of the Permian and Mesozoic, and some of the Mesozoic dinosaurs, all of which are described in separate articles. See DRAGON; HOLBROOKIA; and Plates of LIZARDS; IGUANAS AND OTHER AMERICAN LIZARDS.

LIZARD FISH. One of a family (Synodontidæ) of marine fishes of the order Iniomi (q.v.), which have elongated bodies, very wide mouths, small close scales, and usually photophores. Some inhabit deep waters, and others live near shore, mostly in the tropical regions. The name ordinarily refers in America to a mottled-olive (yellowish beneath) species (*Synodus fœtens*), common from South Carolina to Brazil on sandy shores, which is known also as lagarta, galliwasp, and soapfish. It reaches a length of 12 inches, and, like the other species, is voracious and active. A well-known larger species of southern Europe (*Synodus saurus*) is known among the Italians as lacerto and tarentola. See Plate of LANTERN FISHES.

LIZARD HEAD. The southernmost cape of England, in Cornwall, a bold headland amid picturesque cliff and rock scenery which attracts many tourists, 16 miles southwest of Falmouth (Map: England, A 6). It is surmounted by two fine lighthouses visible 21 miles. It is the *Promontorium Damnonium* of Ptolemy. The name Lizard is also applied to the peninsula of which the Head is the southern point.

LIZITA, lė-sē′tȧ. See MULLET.

LJUNGGREN, lyụng′grān, GUSTAF HÅKON JORDAN (1823–1905). A Swedish critic, born at Lund. He studied in his native town, was made docent of æsthetics at the university there in 1847, and in 1859 professor of æsthetics and literature. In 1847 he obtained the doctorate. From 1875 to 1885 he was rector of the university. His principal work is *Svenska vitterhetens häfder efter Gustaf III.'s död* (5 vols., 1873–95), and his other literary and critical studies include: *Svenska dramat intill slutet af sjuttonde århundradet* (1864); *Bellman och Fredmans epistlar* (1867); *Smärre skrifter* (3 vols., 1872–81); *Från en resa* (1871).

LLAMA, lä′mȧ (the native name). A South American quadruped of the camel family. It is no longer regarded as a distinct species, but as a domesticated variety of the guanaco (q.v.). It was in general use as a beast of burden on the Peruvian Andes, and the only beast of burden used by the natives of America, before the horse and ass were introduced by Europeans. It is still much used in this capacity on the Andes, the peculiar conformation of its feet enabling it to walk securely on slopes too rough and steep for any other animal. The burden carried by the llama should not exceed 125 pounds. When too heavily loaded, the animal lies down and refuses to move, nor will either coaxing or severity overcome its resolution. It is generally very patient and docile. Indeed it has almost no means of efficient offense, although it sometimes attempts to bite. A very disagreeable manner of expressing its feelings is by spitting. Its saliva is of an unpleasant odor, and it can eject this with considerable force and accuracy. Visitors to zoölogical gardens are often witness to this habit, and a riding llama will, when aggravated, occasionally turn its head and spit at its rider. Its rate of traveling is about 12 or 15 miles a day. The llama is about 3 feet in height at the shoulder, has a long neck, and carries its head elevated. The females are smaller and less strong than the males, which alone are used for carrying burdens. The color is various, generally brown with shades of yellow or black, frequently speckled, rarely quite white or black. The flesh is spongy, coarse, and not of agreeable flavor. The hair or wool is inferior to that of the alpaca, but is used for similar purposes: that of the female is finer than that of the male. The llama has been introduced with the alpaca into Australia, but it is only adapted for steep mountain regions and has never become generally useful. See LAMA; ALPACA. See Plate of CAMELS AND LLAMAS.

LLANDUDNO, lȧn-dụd′nȯ, *Welsh pron.* thlȧn-did′nȯ. A fashionable watering place in Carnarvonshire, North Wales, situated between the Great and Little Orme's heads, 40 miles west-southwest of Liverpool (Map: Wales, C 3). It has picturesque surroundings, a fine beach for bathing, pier, marine drive 5½ miles long, promenade, golf links, hydropathic establishments, and good hotels. At the top of the Great Orme stands the small and primitive church of St. Tudno, from which the town takes its name. Llandudno is noted for its exceedingly bracing climate, which attracts about 50,000 visitors each year, chiefly from Lancashire. The town owns its water, gas, electric-lighting, and power works in connection with a refuse destructor, and maintains abattoirs and markets. Pop., 1901, 9300; 1911, 10,469.

LLANELLY, thlȧ-nĕth′lĭ. A market town and seaport in Carmarthenshire, Wales, 10 miles west-northwest of Swansea (Map: England, B 5). It has large copper, iron, and tin-plate works, potteries, and neighboring coal mines. Its docks are commodious, and it carries on an important shipping trade in its industrial products. The town is progressive and owns its water works, markets, two market halls, abattoir, athenæum, two town halls, park, pleasure grounds, free library, and considerable remunerative real estate. The United States is represented by a consular agent. Pop., 1901, 25,600; 1911, 32.071.

LLANES, lyä′nȧs. A town on the north coast of Spain, in the Province of Oviedo, 44 miles west of Santander (Map: Spain, C 1). It has a Gothic church built in the fourteenth century, a well-equipped high school, a new municipal hospital, and many interesting old buildings, among which are the ruins of an old fortress and several ruined palaces and convents. The town manufactures butter, cheese, pottery, and leather. It was formerly of considerable commercial importance, but its small, shallow harbor is now used only by a few coasting vessels. Pop., 1900, 18,781; 1910, 21,779.

LLANGOLLEN, lăn-gŏth′len, *Welsh pron.* thlȧn-gŏth′len. A town in Denbighshire, Wales, picturesquely situated on the Dee in the hill district (Map: England, C 3). The town is a great tourist resort, famous for the beautiful Vale of Llangollen and its antiquities. Among its interesting features is the bridge built in 1346 and considered one of the *Tri Thlws Cymru* (three beauties of Wales). Near Llangollen is Valle Crucis Abbey, the ruins of an ancient Cistercian foundation, the most important monastic ruin in Wales. The abbey church, dating from 1250, contains a fine rose window still in good preservation, and there are considerable remains of the original monastic buildings. Plas Newydd, the residence of the celebrated "Ladies of Llangollen," lies just outside the town. These ladies, Lady Eleanor Butler and the Hon. Sarah Ponsonby, swore eternal friendship, and, leaving their homes in 1776, lived here together till the death of the former in 1829, the survivor living two years more. The house was bought for them with the savings of their faithful servant, Mary Carryl, who died in 1809. Pop., 1901, 3300; 1911, 3249. Consult Robert Simpson, *History of Llangollen* (3d ed., Llangollen, 1852).

LLANO ESTACADO, lä′nȯ, *or* lyä′nȯ, ȧ′stȧ-kä′ᴅȯ. An extensive level plateau in northwest Texas and southeast New Mexico (Map: New Mexico, F 4). It forms a part of the Great Plains along the east slope of the Rocky Mountains, from which it is separated by the valley of the Pecos River. It is about 400 miles north and south, by about 150 miles east and west. It reaches its maximum altitude, 5500 feet, on its west border, whence it slopes southeastward, its east and south borders having an altitude of about 2000 feet. It is bounded on all sides by steep escarpments or palisades, whence its Spanish name, which means 'palisaded plain.' These are highest on the east side, where they are eroded into very irregular lines by the headwaters of the numerous Texas rivers flowing into the Mississippi and the Gulf of Mexico. The top of the plateau is an arid waste almost destitute of surface water. Considerable quantities of water, however, collect during the wet season on the impervious bedrock which underlies the porous sandstone and can be obtained by boring. During the wet season, also, the plateau produces grass enough to support cattle, but agriculture cannot be carried on without irrigation.

LLANOS, lä′nōz, *Sp. pron.* lyä′nȯs (Sp., plains). A common term in Spanish America for treeless plains, or prairies. In a restricted geographical sense it is applied to the great level tract in Venezuela and Colombia between the Orinoco on the east and the first foothills of the Andean Cordillera on the west, and stretching from the northern coastal regions of Venezuela to the forested regions of the Amazon basin. This region, measuring about 150,000 square miles, is elevated only a few hundred feet above the sea and for great distances presents an unbroken expanse of flatland. The lower portions (*llanos bajos*) lying along the rivers are subject to inundation during the wet season from June to October; they support a heavy growth of grass, which generally remains green throughout the year. The highest stretches (*llanos altos*) are more or less diversified by undulating or flat-topped hills; they present a changing appearance, being grass-covered during the wet season and almost barren in the dry months. Grazing is the chief industry of the inhabitants (*llaneros*), who are a mixed race of Spanish and Indian blood. The climate is hot, generally moist, and in some regions malarial. See VENEZUELA; COLOMBIA.

LLANQUIHUE, lyȧn-kē′wȧ. A province in south Chile, bounded by the Province of Valdivia on the north, Argentina on the east, the Province of Chiloe on the south, and the Pacific Ocean on the west (Map: Chile, E 6). Its area is 35,396 square miles. The surface is mountainous in the east and west, while in the centre is a valley occupied by Lake Llanquihue (q.v.), the largest in Chile. The province is well watered and to a great extent covered with forests. The climate is humid but healthful. The chief occupations are agriculture, stock raising and forestry, and considerable quantities of agricultural and animal products and timber are exported to parts of Chile as well as to Germany. The inhabitants numbered 105,043 in 1907 and were estimated at 116,094 in 1911. The capital, Puerto Montt, on the south coast of the province, has a good harbor and an estimated population of 6000.

LLANQUIHUE. The largest lake in Chile.

It is situated in the province of the same name and at the base of the volcano of Osorno (Map: Chile, E 6). It is 30 miles long and of the same width and is of great depth. The lake receives hardly a single tributary, being fed by water filtered through the porous volcanic rock of the region. Its outlet to the sea is through the Maullin River. It was discovered by Pedro Valdivia in 1552.

LLEREN, lyā′rĕn. A name given to *Calathea allouya*, a plant of the family Marantaceæ. It has long been cultivated in Porto Rico for its small, crisp, nutlike tubers, which are formed in great abundance and which are highly prized for food.

LLEWELLYN AP GRIFFITH, lōō-ĕl′ĭn ȧp grĭf′ĭth, or Llywelyn ab Gruffydd (?–1282). A native prince of Wales. He and his brother succeeded their uncle, David ap Griffith, in 1246; in 1254 they quarreled, and Llewellyn, conquering his brother, became sole ruler. He revolted from his allegiance to the English in 1256 and joined with the party of Montfort, but made peace with Henry III in 1267. On the accession of Edward I he refused to do homage. His fiancée, Eleanor de Montfort, was captured by the English in 1275, and war followed in 1276. The English invaded his territory, and in 1277 he surrendered part of his domains and went to London, while Eleanor was given back to him. He soon returned to Wales and renewed the war with the English by a sudden revolt on Palm Sunday, 1282; he was slain December 11 of the same year. Consult: Charles Bémont, *Simon de Montfort* (Paris, 1884); J. E. Morris, *Welsh Wars of Edward I* (Oxford, 1901); T. F. Tout, *Political History of England* (London, 1905).

LLORENTE, lyô-rân′tâ, Juan Antonio (1756–1823). A Spanish historian, born at Rincon del Soto, near Calahorra, in Aragon. He took holy orders in 1779, but turned to the study of canon law, became advocate of the Council of Castile in 1781, vicar-general of Calahorra in 1782, and general secretary of the Inquisition in 1789. A Liberal of the party of Jovellanos (q.v.), he lost his employment when Jovellanos fell in 1801. In 1805 he won the favor of Godoy by an attack on the liberties of the Basque Provinces, published in the form of an historical essay. When the French invaded Spain, Llorente attached himself to King Joseph, under whose order he investigated the archives of the Inquisition for two years after its abolition in 1809. Later he directed the abolition of the convents and the administration of their property. He had to flee to France on Napoleon's downfall in 1814. There he lived till 1822, when the publication of *Portraits politiques des papes* caused his banishment at the instigation of the clergy. Llorente's most important work is the *Histoire critique de l'inquisition d'Espagne* (1817–18). He also wrote the *Memorias para la historia de la revolución española* (1811–16) and an autobiography (1818). Consult A. J. Méhul, *Notice biographique sur Don J. A. Llorente* (Paris, 1824).

LLOYD, loid, Francis Ernest (1868–). An American botanist, born in Manchester, England, and educated at Princeton University (A.B., 1891; A.M., 1895), Munich, and Bonn. Between 1891 and 1912 he was a member of the faculties of Williams College, Pacific University, Teachers College (Columbia), Harvard Summer School, and Alabama Polytechnic Institute (professor of botany, 1908–12). After 1912 he held the chair of botany at McGill University, Montreal, Canada. He served as an investigator in the Desert Botanical Laboratory of the Carnegie Institution in 1906 and as cytologist of the Arizona Experiment Station in 1907, and in 1907–08 directed investigations for the Continental-Mexican Rubber Company. He edited *The Plant World* in 1905–08; was coauthor of *The Teaching of Biology in the Secondary Schools* (1904; 2d ed., 1914) and author of *The Comparative Embryology of the Rubiaceæ* (1902), *The Physiology of Stomata* (1908), and *Guayule* (1911); and contributed to the New International Encyclopædia.

LLOYD, Henry Demarest (1847–1903). An American writer on economic subjects, born in New York City. He was educated at Columbia University, was for a time lecturer on political economy in New York schools, later studied law, and was admitted to the bar in 1869. From 1872 to 1885 he was with the *Tribune* of Chicago, latterly in an editorial capacity. He also held the secretaryship of the American Free Trade League. The first of his publications, *A Strike of Millionaires against Miners* (1890), told the story of the troubles at the Spring Valley (Ill.), coal mines in 1889. Later writings, many of which appeared posthumously, include: *Wealth against Commonwealth* (1894); *Labor Co-Partnership in Great Britain and Ireland* (1898); *The Country without Strikes: New Zealand* (1900); *Newest England: New Zealand and Australia* (1900); *Man, the Social Creator* (1906); *A Sovereign People: A Study of Swiss Democracy* (1907); *Men, the Workers* (1909); *Lords of Industry* (1910); *Mazzini and Other Essays* (1910).

LLOYD, William (1627–1717). Bishop of Worcester, England. He was born at Tilehurst, Berkshire; was educated at Oriel College, Oxford; was ordained priest in 1656 and appointed chaplain to Charles II; became Dean of Bangor in 1672; and was made Bishop of St. Asaph in 1680, Bishop of Lichfield and Coventry in 1692, and Bishop of Worcester in 1700. He took an active part in the religious controversies of his time and was one of the seven bishops imprisoned in the Tower for their protest against the declaration of indulgences to Catholics and Dissenters by King James II. He supported the revolution of 1688 and was appointed almoner to William and Mary and to Queen Anne. He furnished valuable materials to Bishop Burnet's *History of my Own Time* and, besides pamphlets on the Roman Catholic controversy, tracts, and sermons, published: *A Chronological Account of the Life of Pythagoras and of his Famous Contemporaries* (1699); *A Dissertation on Daniel's Seventy Weeks* (1690); *A System of Chronology* (1690).

LLOYD, William Watkiss (1813–93). An English classical and Shakespearean scholar, born at Homerton, Middlesex. Without university training and despite 36 years given mostly to an uncongenial business, he made for himself a recognized place as a learned and acute critic and as a connoisseur. Trustworthy from the standpoint of scholarship, his work is weak in concision, in artistic arrangement, and in the literary graces. On the classical side it is well represented by *Xanthian Marbles* (1845), *The History of Sicily* (1872), and *The Age of Pericles* (1875). As a Shakespearean critic, he may be advantageously known by his essays scattered through the Singer edition (1856, 1875) of the dramatist, by his prefatory essay to his edition of *Much Ado about Nothing* (1884), and by contributions to periodicals and the transactions of learned societies. For further biographic and bibliographic information, consult the memoir, by Sophia Beale, prefixed to Lloyd's posthumously published *Elijah Fenton: His Poetry and Friends* (London, 1894).

LLOYD-GEORGE, David (1863–). A British statesman and reformer. He was born in Manchester, of Welsh parentage. His father, a poor and invalid schoolmaster, died in early manhood, and Lloyd-George was brought up under humble circumstances in Wales by an uncle, a Baptist shoemaker. The boy pushed his way upward through school, studied for the law, and thrust himself, while yet in his teens, into the first ranks of those Welshmen who contended most vigorously for complete freedom from the dominance of the Church of England. As winner of a great lawsuit that involved the right of burial in parochial burying grounds, he became well known, and in 1890 he was elected to Parliament, a member of which he remained thereafter without interruption. The first 10 years of his parliamentary career were in no wise remarkable. The little lawyer, without influence, without money, without even the advantages of university training or environmental culture, bade fair to be known simply as a fiery and intransigent Welshman. But the Boer War changed all this. Throughout that struggle Lloyd-George fought the government tooth and nail. The Liberal party, completely torn asunder by the conflict, offered but a feeble opposition towards the war; not so Lloyd-George. The Boer cause was his cause, and for the enemy of Great Britain he contended warmly, even to the imminent danger of his life; for during these trying years, hated, abused, and even mobbed, he was the most unpopular man in Great Britain. But during the period of reaction that followed close on the heels of war the reputation of Lloyd-George rose rapidly. His stalwart independence, brilliant debating, and sheer ability made his inclusion in the Liberal ministry of 1906 almost inevitable, and there were few who thought his inclusion even in the cabinet itself, as President of the Board of Trade, an undeserved appointment. In this office, indeed, he won high opinions from all sides; his masterful treatment of the Port of London imbroglio and of controversies arising from foreign patents won approval even in the highest financial circles of the conservative city.

In 1908 Lloyd-George was made Chancellor of the Exchequer, and as such found himself sponsor for an old-age pension bill, already in its main outlines drawn up by his predecessor. It met with sharp and caustic criticism, but was defended with such marked ability that on its passage Lloyd-George's reputation was greatly heightened. (See Old-Age Pensions.) Next came his great accomplishment, the famous Lloyd-George budget. To pay for old-age pensions and other social legislation of the new government, such as increased grants for elementary education, town planning, labor exchanges, etc., without diminishing the cost of naval preparations, required increased taxation. The Unionists proposed that it should come from tariff imposts; but Lloyd-George had another plan, and this he outlined in his budget speech on April 19, 1909. His proposals in brief were these: first, increased indirect taxation, by heavier taxes on tobacco, spirits, and a new tax on petrol used for motor cars; second, increases in the income tax, particularly on unearned incomes, and an additional supertax on incomes over £500; third (and this is the most revolutionary feature of his budget), a land tax which would confiscate for the state no less than 20 per cent of all increase in land valuation, with due exception for improvements. Financial London stood aghast at the scheme; the great banking houses, such as Rothschilds, united to oppose it; even Lord Rosebery, ex-Premier of Great Britain, came forth from his retirement to denounce it; and Lloyd-George soon found himself the centre of a fiery battle in which his vehemence and passion found full play. Adored by his supporters, hated by his enemies, Lloyd-George infused into his speeches such a daring wealth of invective and satire as even British politics had never called forth. The budget was rejected by the House of Lords by a vote of 350 to 75, despite the well-recognized principles that over money bills it had no customary jurisdiction, and on Dec. 3, 1909, Parliament was prorogued, and a new election ordered. The Liberals were returned to office with a majority of only two over the Unionists—a situation which necessitated their coalition with the Irish Nationalists and the Labor party. But the successful passage of the budget was secured eventually. See Tax.

During the ensuing year Lloyd-George actively defended the Parliament Bill, which aimed to cripple the veto power of the House of Lords; but the main brunt of the defense of that measure fell upon the Premier, Asquith (q.v.). In 1911, however, Lloyd-George became again the foremost figure in British politics by the presentation of the second of his great reforms, the National Insurance Bill. (See Workingmen's Insurance.) The year 1912 made no especial claim upon the services of the Chancellor of the Exchequer. And even in the matter of the disestablishment of the Anglican church in Wales, a measure dear to Lloyd-George's heart, the bill for its provision was officially in the hands of the Home Secretary, Reginald McKenna. When Irish Home Rule became the most pressing problem in British politics, it was Asquith who played the foremost Liberal rôle. In 1913 a government commission investigated a financial transaction, indiscreet though not dishonorable, in which Asquith, Lloyd-George, and other ministers had become involved. This was the purchase of shares in the American Marconi Wireless Company—a concern which had been subsidiary to, and which at the date of purchase was popularly believed closely allied with, the British company of the same name—and the latter at that time was negotiating for important government contracts.

In the same year Lloyd-George embarked upon a great and comprehensive reform campaign—one to free the land by breaking up the great estates, restoring the land to the people, and repopulating the half-deserted farm land of Great Britain. The instrument for accomplishing this end would seem to be ultimately land nationalization; the immediate weapon, a minimum-wage law for farm laborers, a law to safeguard tenant expenditures for improvements, extremely rigid inspection and building laws in the cities. (See SINGLE-TAX AND LAND NATIONALIZATION.) Beginning in the summer of 1914, the European War dwarfed all domestic interests. It devolved upon the Chancellor to arrange for war loans greater than had ever been required before. The financial situation, which was at first strained and uncertain, soon became normal again. (See WAR IN EUROPE.) In Asquith's coalition cabinet, formed May, 1915, R. McKenna succeeded Lloyd-George, who took the new post of Minister of Munitions.

Lloyd-George, unlike most British statesmen, gained distinction both in parliamentary debate and on the hustings. Without impressive figure or particularly powerful voice, not widely read nor trained in English history, nor even careful to ascertain the full truth of his many accusations, this leader, by his ability to coin words, expressions, phrases, that would catch like wildfire with the masses, by his vehemence, and his passion for the public weal, combined with a long and intimate acquaintance with the English Bible, made himself the most influential orator in Great Britain. Lloyd-George published: *Better Times* (1910), speeches; *The Call of Liberalism* (1912); *People's Insurance* (3d ed., containing text of the National Insurance Act of 1911, with explanations of the insurance commissioners, 1912). Consult, for a flattering review of his early life, J. H. Edwards, *From Village Green to Downing Street* (London, 1908); for a hostile account, G. E. Raine, *The Real Lloyd-George* (ib., 1913); for a detailed biography, Edwards and Duparc, *Life of David Lloyd-George* (4 vols., ib., 1913); and for the Lloyd-George policies, H. A. Walter, *Die neuere englische Sozialpolitik; mit einem Geleitwort des englischen Schatzkanzlers, David Lloyd-George* (Munich, 1914).

LLOYDS, loids. An incorporated association of underwriters, merchants, shipowners, ship brokers, and insurance brokers. The home office of the association is in London, where it occupies a suite of rooms in the Royal Exchange. The objects for which the association was formed are, according to the act of incorporation: (*a*) carrying on the business of marine insurance; (*b*) the protection of the interests of the members of the association; and (*c*) the collection, publication, and diffusion of intelligence and information with respect to shipping. The association is composed of members and subscribers, and no others are allowed to avail themselves of the privileges of the rooms. The members are of two classes, underwriting members who pay an entrance fee of £100 and are required to deposit securities to the value of £5000 to £10,000 as a guarantee of their engagements, and nonunderwriting members who pay a fee of 12 guineas. Subscribers pay an annual subscription of five guineas, but no entrance fee, and have no voice in the management of the affairs of the association. The management of the association and its operations is delegated to the "committee for managing the affairs of Lloyds," selected by the members from among themselves. Routine work is carried on by a secretary and assistants and a large clerical staff. The method of effecting insurance is for a broker to write upon a slip of paper the name of a ship and of her master, the character of the cargo, the amount at which it is valued, nature of the voyage, etc. If the risk is accepted, each underwriter subscribes his name and the amount of it which he will underwrite, the insurance being effected as soon as the total amount is made up. As the premium rate largely depends upon correct information upon all points connected with the risk in question, one of the first requisites of the association has been an efficient maritime intelligence department, and in the development of this the greatest success has been achieved.

The association of Lloyds had its origin over 225 years ago in the meeting of merchants for business and gossip in the coffeehouse kept by Edward Lloyd in Tower Street, London. The earliest mention of these meetings appears in the London *Gazette* of Feb. 18, 1688, but the character of the notice implies that they were then no new thing. Their growing importance led Mr. Lloyd to remove to Lombard Street in 1692, and soon afterward he began the issue of *Lloyd's News*, devoted to mercantile and maritime information, eventually succeeded by *Lloyd's List* (published daily), the second oldest newspaper in London. The merchants and underwriters continued to meet in the same manner during the greater part of the eighteenth century without any apparent organization or rules; but, as the business increased in volume, the merchants, underwriters, and associates moved first to a building in Pope's Head Alley and finally, in 1774, to the Royal Exchange. The association adopted in 1779 a printed form of policy differing but little from that in use to-day.

In 1811 the society was reorganized and in 1871 incorporated. Its agents are to be found in every maritime port in the world frequented by deep-sea ships. *Lloyd's Register of British and Foreign Shipping* is a volume published annually, containing information respecting vessels, their age, material, repairs, owners, captains, etc.; also details of docks and other maritime information. The office of the *Register* is distinct from Lloyd's of the Exchange.

The classification of ships, as regards their construction and seaworthiness, made by Lloyds surveyors and contained in the registers, dates from the middle of the eighteenth century, and in the earliest copy extant of *Lloyd's Register of Shipping*, dated 1764–65–66, vessels are classified in groups, designated by the letters A, E, I, O, U; A standing for a first-class ship. With these letters were used G, M, and B, referring to the equipment, and indicating whether it was good, middling, or bad. In the *Register* of 1768–69 the numbers 1, 2, 3, 4 are employed to denote the condition of the equipment, and the letters A, E, I, O, U are printed small. In the *Register* 1775–76 the hull is again described by Roman capital letters and the equipment by the figures 1 and 2. As iron ships began to be used, it was found necessary to classify them into grades, and in 1869, on the adoption of new rules for shipbuilding, numbers were used for iron ships, and a system of classification followed which in the main is still used. This classification of ships was determined by rules adopted to govern shipbuilders and was universally recognized by merchants and others, as it enabled them to determine the seaworthiness of a vessel by consulting the register. See articles A1 and SHIPS, CLASSIFICATION OF, FOR MARINE INSURANCE, for modern systems of classifying wooden and iron ships; LOAD-LINE MARKS OF VESSELS. Consult the occasional publications of Lloyds; Lloyd's *Rules for the Building and Classification of Ships;* and *Annals of Lloyd's*

Register of British and Foreign Shipping (London, 1884).

LLOYDS, Austrian. An association for general commercial and industrial purposes, founded in Triest by Baron Bruck in 1833, to supply the want, experienced by the maritime insurance companies of that port, of a central administration to attend to their common interests. This association, like its London prototype, has agents in all the principal foreign ports, whose duty it is to collect all information of a nature to affect the commerce and navigation of Triest and to keep a list of all entrances and clearances of ships at their respective ports. This information is published in the *Giornale del Lloyd Austriaco.* This company has established regular communication between Triest and all the important seaports in the Adriatic and Levant, by means of a large fleet of steamers, which also carry the Austrian mails. The society of Austrian Lloyds includes three sections: the first is composed of insurance companies, the second of steamboat companies, while the third or scientific department (established in 1849) has a printing establishment, an engraving room, and an artistic establishment for the perfecting of engraving on copper and steel. This last section has issued a great number of literary and scientific journals.

LLOYD'S BOND. The name of a security much employed in England during the period of railway construction, between 1850 and 1870, when railway companies were hampered by parliamentary restrictions upon their borrowing power. A Lloyd's bond, so called because introduced by Mr. John Horatio Lloyd, an English barrister, is a sealed acknowledgment of indebtedness and can be issued by companies in return for materials or services rendered, but cannot be sold for money. They have been held by the courts to be a valid claim upon the property of a company and to give the holder preference over ordinary creditors, although they possess no priority over debenture or mortgage bonds issued in accordance with the provisions of a company's charter. They constitute a preferred part of a company's floating indebtedness. English railways now have abundant borrowing power under the statutes and are no longer issuing Lloyd's bonds.

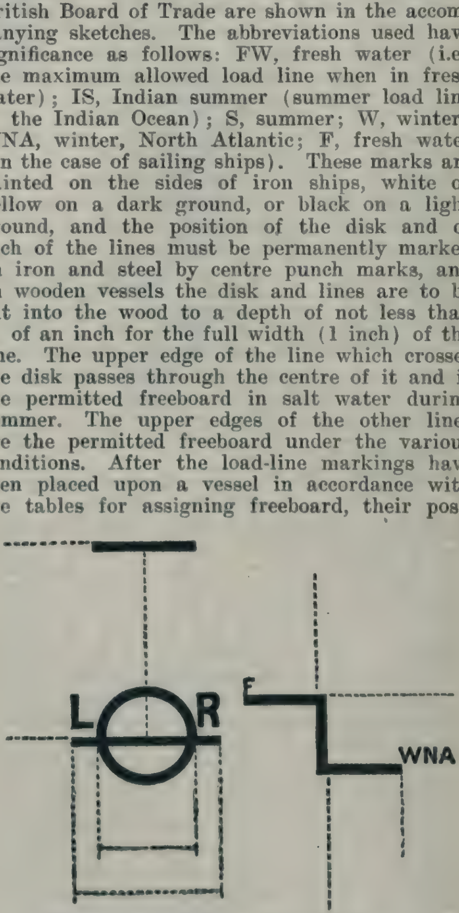
LLYWELYN AB GRUFFYDD. See Llewellyn.

LOACH, lōch, or Groundling (Fr. *loche,* Sp. *locha, loja,* loach). A fish of the family Cobitidæ, closely related to the carp family, which has an elongated body, covered with small scales, and a small head with 4 to 10 barbules around the mouth. The common species (*Nemacheilus barbatulus*) of the rivers and brooks of Great Britain seldom exceeds 4 inches in length and is highly esteemed by anglers and for food. The lake loach (*Misgurnus fossilis*) of the Continent is sometimes a foot long and inhabits the mud of stagnant waters, which gives its flesh a bad flavor. See Plate of Carp and their European Allies.

LOADING, Density of. See Ballistics.

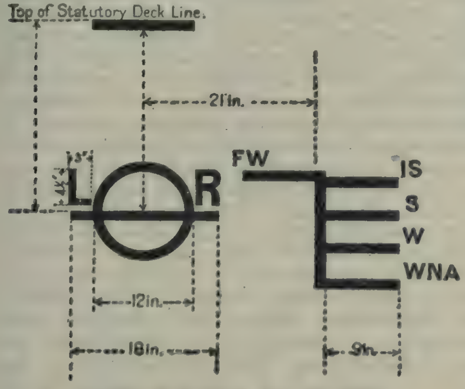
LOADING TRAY. A contrivance designed to facilitate the placing of projectiles in the bore of a heavy breech-loading gun without injuring the threads in the screw box or seat of the breech plug. It consists of soft metal or of wood with a lining of thin metal on its upper surface and covers the threads at the bottom of the screw box. The ordinary loading tray must be placed in the breech after it is opened and removed before it is closed. This takes several seconds, and, to avoid the loss of time thus entailed, some recent designs of breech mechanism provide a loading tray which is automatically placed in position.

LOAD-LINE MARKS OF VESSELS. The load line or load water line of vessels is the line in which the plane of the water surface cuts the hull of a ship when the latter is loaded. Many vessels are lost from overloading, and this fact led Samuel Plimsoll (q.v.), a member of the British Parliament, to prepare his Merchant Shipping Act, which became a law in 1876. This act was amended by the Merchant Shipping Acts of 1890, 1894, and 1906 and the marks provided for in those acts and the rules of the British Board of Trade are shown in the accompanying sketches. The abbreviations used have significance as follows: FW, fresh water (i.e., the maximum allowed load line when in fresh water); IS, Indian summer (summer load line in the Indian Ocean); S, summer; W, winter; WNA, winter, North Atlantic; F, fresh water (in the case of sailing ships). These marks are painted on the sides of iron ships, white or yellow on a dark ground, or black on a light ground, and the position of the disk and of each of the lines must be permanently marked on iron and steel by centre punch marks, and on wooden vessels the disk and lines are to be cut into the wood to a depth of not less than ¼ of an inch for the full width (1 inch) of the line. The upper edge of the line which crosses the disk passes through the centre of it and is the permitted freeboard in salt water during summer. The upper edges of the other lines are the permitted freeboard under the various conditions. After the load-line markings have been placed upon a vessel in accordance with the tables for assigning freeboard, their positions must be verified and approved by the Board of Trade, which issues a certificate of approval. This certificate may cease to be in effect after a survey which reduces the vessel in classification; in this case a new certificate must be issued (with possibly a new placing of the marks).



FREEBOARD MARKING FOR SAILING VESSELS.
Dimensions same as for steamers.

When the markings are duly placed, newly or originally, their positions and accuracy are verified by *Lloyd's Register* surveyors, and upon this being reported to the committee, a freeboard certificate is forthwith issued. Without a freeboard certificate issued by Lloyds or by some other authoritative source, no vessel (British or foreign) can clear (the British expression is "enter outwards") from any port in Great Britain. The Committee of *Lloyd's Register* assigns freeboard for foreign vessels in accordance with the tables, if the owners make application for the assignment, and it issues, with the concurrence of the Board of Trade, certificates similar to those given British vessels.



FREEBOARD MARKING FOR STEAMERS.

The position of the "statutory deck line," from which the load lines are measured, is defined in the Merchant Shipping Act of 1876 as follows:

"Every British ship (except ships under 80 tons' register employed solely in the coasting trade, ships employed solely in fishing, and pleasure yachts) shall be permanently and conspicuously marked with lines of not less than 12 inches in length and 1 inch in breadth, painted longitudinally on each side amidships, or as near thereto as practicable, and indicating the position of each deck which is above water.

"The upper edge of each of these lines shall be level with the upper side of the deck plank next the waterway at the place of marking.

"The lines shall be white or yellow on a dark ground, or black on a light ground."

The line abreast the uppermost deck which extends the full length of the ship is the "statutory deckline."

Under the British Merchant Shipping Act of 1894, the Committee of *Lloyd's Register* is empowered to assign freeboards to British vessels as required by the act. The form of marking adopted by Lloyd's is shown in the sketches, the letters L and R on each side of the disk indicating that the freeboards were assigned by the committee. If the freeboard is assigned by the Board of Trade surveyors, the letters B and T replace the L and R in the foregoing plans. In 1906 the British Shipping Laws were amended so that all foreign vessels loading at British ports are required to be provided with a freeboard mark assigned under the British rules and in accordance with the British tables, or under rules and tables of a foreign country which had been certified by the British Board of Trade as being equally effective with the British rules and tables. In the same year the British freeboard tables were revised, and important modifications made. In 1907 Germany adopted tables very similar to the British, while France, Holland, Denmark, Sweden, and Spain have adopted the British rules. All other nations are likely soon to follow their lead or prepare tables of their own. Consult: *Lloyd's Seaman's Almanac* (London, 1893); *Lloyd's Rules and Regulations for the Construction and Classification of Steel Vessels* (ib., new editions from time to time); *Instructions to Measuring Surveyors* (ib., new editions from time to time). Also see Lloyds; Ships, Classification of, for Marine Insurance; Registry of Vessels; Measurement of Ships.

LOAD′STONE. See Magnetite.

LOAISA CARVAJAL, lō-ī′sȧ kär′vȧ-häl′, Jerónimo (?1489–1575). A Spanish missionary to South America, born at Trujillo. He entered the Dominican Order at Córdoba, taught at Valladolid, was prior of Carboneras, became Bishop of Cartagena de Indias in 1537, built a cathedral, and established a school. He was transferred to the see of Lima, arriving in 1543, and was later (1548) made the first Archbishop. He acted as peacemaker in several rebellions, but after the death of the Viceroy, Mendoza, took the field against Girón. His chief work was the establishment of the Hospital of St. Anne, which is still in existence.

LOAM (AS. *lām*, OHG. *leimo*, Ger. *Leim*, *Lehm;* connected with AS. *līm*, Eng. *lime*, Lat. *limus*, mud, and ultimately with AS. *slīm*, Ger. *Schleim*, Eng. *slime*). A term widely though loosely employed by agriculturists and others to designate a soil consisting of a mixture of clay, sand, and decomposing organic matter (humus). Correctly used, loams are soils having a texture intermediate between sand and clay and contain a mixture of gravel, sand, silt, and clay in such proportions that the properties of no one of these textural groups predominate. They therefore lack the excessive porosity of sandy soils and the compactness of clay. Loams have a desirable structure, but are usually somewhat sticky when wet. They may be calcareous. A number of types of loamy soils can be recognized, depending upon the predominance of certain textural soil particles. We thus have sandy loams, silt loams, clay loams, gravelly loams, and stony loams. Although loam is of importance as a soil type, it may also be used for making bricks if clayey enough, and the more sandy varieties are often used for foundry sand. Consult L. L. Van Slyke, *Fertilizers and Crops* (New York, 1912). See Soil; Clay; Marl; Sand.

LOAN (AS. *lān*, *læn*, OHG. *lēhan*, Ger. *Lehen*, *Lehn*, loan; connected with Goth. *leihwan*, AS. *lēon*, OHG. *līhan*, Ger. *leihen*, to lend, OIr. *leicim*, I leave, Lith. *likti*, Lat. *linquere*, Gk. λείπειν, *leipein*, Skt. *rich*, to leave). In law, either the delivery of money or any article of personal property by one person to another for which an equivalent return in kind is to be made, or the bailment of a personal chattel to be specifically returned to the person making the loan. An important distinction to be noted between the two classes of loans is that in the first kind title to the property lent passes to the borrower and the person making the loan has in the case of a chattel only a contract right to recover damages if the borrower fails to keep his agreement, and in the case of money to recover the amount loaned in an action of debt. Whereas in the second class the borrower acquires possession only as bailee and not the title to the property borrowed, and the lender may compel a return of the property lent by an action in replevin or may recover damages for its conversion (see Trover) if the borrower fails to return it.

The second class of loans may belong either to the class of bailments for the mutual benefit of the bailor and bailee, in which case the bailee is bound to exercise due care for the safety of the property lent—i.e., such care as a prudent man would take of his own property—or they may belong to the class of gratuitous bailments, the delivery of an article to the bailee, for his use, without compensation, and on condition of its return to the bailor. As this kind of bailment is entirely to the advantage of the bailee, he is bound to use extraordinary care and is responsible for slight negligence in the use of the bailment. He is not responsible for the natural deterioration by ordinary wear and tear of the article delivered, but with that exception must return the article to the bailor in as good condition as when it was received. The diligence to which the bailee is held in the care of the property depends upon its character and value and the dangers to which it is exposed. Consult the authorities referred to under Contract. See Bailment.

LOAN ASSOCIATIONS. See Building and Loan Associations.

LOANDA, lō-än′dȧ, Saint Paul de. A seaport of Africa. See Saint Paul de Loanda.

LOANGO, lō-äṉ′gō. A coast district of West Africa, extending about 200 miles northward from the mouth of the Congo to the vicinity of Mayumba (Map: Africa, F 5). The coast is partly low and marshy, partly steep and rocky, and the interior rises in terraced plateaus. The chief products are palm oil and rubber. The northern half of the district lies within French Equatorial Africa; the extreme southern part belongs to Belgian Congo, while the middle portion, called Cabinda (q.v.), belongs to Portugal. The Loango district was originally a part of the native Congo Empire. It was then for a time an independent native kingdom until the arrival of the Portuguese, the Dutch, and the French, in the seventeenth and eighteenth centuries. It was for a long time the centre of the West African slave trade. The chief settlement is Loango.

LOANGO. The chief settlement on the French Loango (q.v.) coast, West Africa, and the principal commercial port of French Equatorial Africa, situated 100 miles north of the mouth of the Congo River (Map: Congo, B 3). During the independence of the native Loango State it had a population of over 15,000, but is now little more than a collection of European trading factories. It has a well-sheltered roadstead, but so shallow that ships lie 3 miles off the shore and discharge into lighters. It is connected with Brazzaville, the capital of the French Middle Congo, by telegraph and with Europe by the submarine cable.

LOBACHEVSKY, lō′bȧ-chĕf′skē, Nikolai Ivanovitch (1793–1856). A Russian mathematician, born at Nizhni Novgorod, the son of a peasant. He studied at Kazan, where he became adjunct professor of mathematics in 1814 and professor in 1816. He held this position for 40 years, and for 19 years he was rector of the university. In 1829–30 he published the first geometry which was not based upon the Euclidean postulate of parallel lines (see Geometry) and thus became the founder of the non-Euclidean geometry. (See also Bolyai.) His works are as follows: *Principles of Geometry* (original in Russian, 1829–30); *Imaginary Geometry* (original in Russian, 1835); *New Principles of Geometry, with a Complete Theory of Parallels* (original in Russian, 1835–38); *Geometrische Untersuchungen zur Theorie der Parallellinien* (original in German, 1840; new Ger. ed., 1887; Eng. trans., 1891); *Pangéométrie ou précis fondé sur une théorie générale et rigoureuse des parallèles* (original in French, 1855). His complete works were edited by Janischevsky (1870) and have been translated by Hoüel, Battaglini, and Halsted. A collection of his geometrical writings appeared in Kazan. The first volume of this collection, published in 1883, contains Lobachevsky's Russian articles only and bears a Russian title; the second and last volume, published in 1886, contains his French and German articles, and, besides the Russian title, bears also the following title in French: *Collection complète des œuvres géométriques de N. I. Lobatcheffsky.* Consult: Jules Hoüel, in the *Bulletin des sciences mathématiques* (Paris, 1879); V. P. Vassilieff, *Eloge historique de Nicolas Lobatchevsky* (Eng. trans., Austin, Tex., 1894); Engel, *N. I. Lobatchewsky* (Leipzig, 1899). For his geometry, consult *New Principles of Geometry, with Complete Theory of Parallels,* translated from the Russian by Halsted (Austin, Tex., 1897).

LOBANOV-ROSTOVSKI, lō-bä′nŏf-rō-stŏf′skē, Prince Alexei Borisovitch (1825–96). A Russian statesman. He entered one of the departments of the Ministry of Foreign Affairs in 1844, became attaché of the Russian Embassy at Berlin in 1850, and at the close of the Crimean War became counsel to the Legation at Constantinople, where he was afterward Minister Plenipotentiary from 1859 to 1863. A scandal interrupted his diplomatic career for several years, after which he reëntered public service in the Department of the Interior as Governor of Orel in 1866 and was Assistant Secretary of War in 1867–68. He represented his government at Constantinople, 1878–79; London, 1879–82; and Vienna, 1882–95. In January, 1895, he was appointed Minister Plenipotentiary to Germany, but never started for Berlin, as on the death of M. de Giers he became Minister of Foreign Affairs on February 26 (March 10) of the same year. His policy was vigorous. He died suddenly while traveling to Kiev, Aug. 30, 1896.

LOBAU, lō′bou. An island about 5 miles below Vienna, in the Danube, noted for its connection with the battle of Aspern and Essling, between Napoleon I and the Austrians under Archduke Charles (May 21–22, 1809). From Lobau Napoleon threw bridges across both arms of the Danube, and crossed to the left bank on the 21st. On the night of the 22d the defeated French regained the island and held it until July 4, when the river was again crossed, and the battle of Wagram was won on July 6. For his brilliant work in retaking this island, Gen. Georges Mouton was created Count de Lobau (q.v.) by Napoleon.

LOBAU, lō′bō′, Georges Mouton, Count de (1770–1838). A marshal of France. He was born Feb. 21, 1770, of an obscure family at Pfalzburg in Lorraine. In 1792 he entered the army as a volunteer and served with distinction in the armies of the North and of Italy, becoming in 1799 aid-de-camp to Joubert. In 1800 he became a colonel. Later he attracted the attention of Napoleon, who made him in 1805 his own aid-de-camp, and in this capacity he served during Napoleon's campaigns in Germany. In 1807 he became a general of division and in 1808 he commanded a division in the campaign in Spain. In 1809 he returned to Germany and distinguished himself especially at Landshut and in the battle of Aspern (q.v.), where his brilliant assault on the village of Essling enabled the French to recross the Danube in safety to the island of Lobau, for which service Napoleon created him Count de Lobau and adjutant general. He was taken prisoner by the allied forces after the battle of Leipzig (1813) and returned to France only after the First Restoration. Having supported Napoleon after his escape from Elba and fought at Ligny and Waterloo, he was not allowed to return to France until 1818. After the revolution of 1830 he became commander in chief of the National Guard and was made marshal and peer of France in 1831.

LOB′BY (ML. *lobia*, *lobium*, *laubia*, from OHG. *loubā*, Ger. *Laube*, arbor, from OHG. *loub*, Ger. *Laub*, leaf). That part of the assembly hall of a legislative body where private persons are permitted to enter for the purpose of consulting with members. In the political vocabulary of the United States the term refers also to the persons who frequent this place for the purpose of influencing the votes of legislators. They are called "lobbyists" and their business "lobbying." One of the leading causes of the lobby in the United States is the method of legislation by committees, bills being first discussed by small committees and frequently approved by the legislature after little or no public debate. It may thus happen that a measure of importance to an individual or corporation may be carried through the legislature without arousing the consideration which its real nature demands. This method enables powerful interests to bring pressure to bear upon the legislative committee to induce a favorable report which could not be exerted effectively upon the legislative body as a whole. Corporate interests habitually maintain experienced and influential lobbyists at American legislatures. Several States, notably California and Georgia, have made the business of lobbying a felony. The constitutions of North Dakota and Wyoming declare that the practice of logrolling, which is really a form of lobbying, shall be treated as bribery, while the constitution of South Dakota requires of every member of the Legislature an oath that he has not accepted a free pass on a railroad for any vote which he may cast or influence which he may exercise in the enactment of any law. The New York law of 1906 requiring agents and attorneys representing the interests of corporations before the Legislature to file application with the Secretary of State, setting forth in detail the services they expect to perform, and to make public a sworn statement of all expenses incurred in the performance of such services, is designed to check illegitimate lobbying by corporation agents and all others who thus seek to influence legislation. The courts have repeatedly held that contracts which may have for their object the influencing of legislation in any other than the recognized and legitimate mode must be held void.

Tanner, *The Lobby and Public Men* (Albany, 1888); P. S. Reinsch, *American Legislatures and Legislative Methods* (New York, 1907); Bryce, *The American Commonwealth* (App., 2 vols., ib., 1910); McLaughlin and Hart (eds.), *Cyclopedia of American Government*, vol. ii (ib., 1914); also *First Report of the Interstate Commerce Commission* (Washington, 1887).

LOBE, lō′be, JOHANN CHRISTIAN (1797–1881). A German musician, composer, and writer on musical topics, born at Weimar. He studied the flute and violin, as a pupil of August Riemann and later of A. E. Müller, appeared in 1811 as a solo flutist at the Leipzig Gewandhaus, and became flutist and subsequently viola player in the Weimar grand-ducal orchestra. In 1841–45 he conducted at Weimar an institute for theoretical instruction in music and in 1846 established an institute of music at Leipzig, where he also edited the *Allgemeine Musikalische Zeitung* until it ceased publication in 1848. From 1853 to 1857 he published and edited the *Fliegende Blätter für Musik* and later was musical editor of the *Illustrirte Zeitung* of Leipzig. He also became well known as a writer of sarcastic and witty feuilletons. His compositions, including six operas, two symphonies, quartets for pianoforte and strings, and a number of flute solos, are technically skillful and finished, but rather commonplace in their material. His *Katechismus der Musik* (1851, revised in 1913 by H. Leichtentritt, also in English translation by F. R. Ritter, 1894) is still a valuable book. His most ambitious work, *Lehrbuch der musikalischen Komposition*, in four volumes (1850–67), frequently revised and translated into many languages, enjoyed enormous popularity.

LÖBE, lẽ′be, WILLIAM (1815–91). A German agricultural writer, born at Treben, Saxe-Altenburg. For many years he was a farmer, but in 1840 he removed to Leipzig and began to write on agricultural subjects. Among his numerous works are: *Encyklopädie der gesamten Landwirtschaft* (6 vols., 1850–52; Supp., 1860); *Handbuch der rationellen Landwirtschaft* (7th ed., 1887); *Die Milchwirtschaft* (2d ed., 1889); *Die Geflügelzucht* (4th ed., 1903).

LOBECK, lō′bĕk, CHRISTIAN AUGUST (1781–1860). A German classical scholar. He was born at Naumburg-an-der-Saale, and, after studying at Jena and Leipzig, was professor extraordinarius at Wittenberg from 1810 to 1814, when he became librarian and professor ordinarius of ancient literature and eloquence at Königsberg. He retained the latter post until 1858. He is remembered chiefly for his contributions to the study of Greek grammar and Greek mythology and religion. Among his works were the *Paralipomena Grammaticæ Græcæ* (2 vols., 1837); *Pathologiæ Sermonis Græci Prolegomena* (1843); and the *Aglaophamus, seu de Theologiæ Mysticæ Græcorum Causis* (2 vols., 1829), which is particularly valued for its accurate and exhaustive discussion of the Orphic sect and literature; in opposition to the views of Creuzer (q.v.), in his *Symbolik*, Lobeck in the *Aglaophamus* set forth the actual facts known concerning the mysteries. He also edited some Greek texts, including the *Ajax* (*Aἴας*) of Sophocles, with a commentary (1810; 3d ed., 1866). He made valuable additions to the Greek grammar by Buttmann (q.v.). His selected academic speeches were published by Lehnerdt (1865). Consult: Ludwig Friedländer, *Mitteilungen aus Lobecks Briefwechsel* (Leipzig, 1861); Ludwig, *Ausgewählte Briefe von und an Chr. Aug. Lobeck und K. Lehrs* (Leipzig, 1894); J. E. Sandys, *A History of Classical Scholarship*, vol. iii (Cambridge, 1908).

LOBEIRA, lō-bā′ē-rȧ, VASCO DE (?–?1403). A Portuguese knight who won his spurs in the reign of John I (1385–1433) or in that of Ferdinand II. Fernão Lopes, the chronicler who recorded this, contradicts himself. Lobeira's greatest title to fame is probably undeserved, for more recent investigation tends to deny him the authorship of the romance of *Amadis of Gaul*, which may rather have been written by his father, João Lobeira.

M. de Vasconcellos, "Portugiesische Litteratur," in Gustav Gröber, *Grundriss der romanischen Philologie*, vol ii (Strassburg, 1897); C. M. de Vasconcellos, *Cancioneiro de Ayuda* (Halle, 1904); A. Thomaz Pires, *Vasco de Lobeira* (Elvas, 1905); M. Menéndez y Pelayo, *Orígenes de la novela*, vol. i (Madrid, 1905); G. S. Williams, "The Amadis Question," in *Revue Hispanique*, vol. xxi (New York, 1909).

LOBEL, lō-bĕl′, DE LOBEL, or LOBELIUS, MATTHIAS (1538–1616). A Flemish botanist. He was born at Lille and was educated as a physician. He traveled through Europe and afterward was appointed botanist and physician to James I of England. The genus of plants called *Lobelia* was named after him. He was author of *Stirpium Adversaria Nova* (1570), *Plantarum seu Stirpium Historia* (1576), and *Icones Stirpium* (1581).

LOBELIA (Neo-Lat., named in honor of Matthias von Lobel). A genus of about 250 species, widely distributed, about 30 species occurring in the United States. Some of them are aquatic, but the large majority are terrestrial plants of wet or dry soil. The conspicuous representatives of the genus throughout the eastern United States are *Lobelia cardinalis* (cardinal flower), with very showy scarlet flowers; *Lobelia syphilitica* (great lobelia), with large clusters of conspicuous blue flowers; and *Lobelia inflata* (Indian tobacco), which occurs in fields and thickets, usually in dry soil, and has been used as a medicine from time immemorial by the aborigines of North America and was introduced into Europe in 1829 by Dr. Reece. The chemical constituents of *Lobelia* are an alkaloid, lobelin, a peculiar acid, to which the term "lobelic acid" has been applied, inflatin, lobelacrin, etc. Several species are cultivated for ornament.

LOBELIA INFLATA, INDIAN TOBACCO.

LOBENGULA, lō′bĕn-gōō′lȧ (c.1833–94). A king of the Matabele. He succeeded his father, Mosilikatse, in 1870, made Buluwayo his capital, and boldly opposed European civilization, threatening with death any of his people who accepted Christianity. He had about 10 conquered tribes under him. After the discovery of gold in his territory (1872), Portugal, the Transvaal, and Great Britain strove to win supreme control over Lobengula's kingdom. In 1888 he signed a treaty with England admitting her suzerainty. Two years afterward the British South Africa Company obtained permission to settle in Mashonaland, and for three years it paid the King a yearly rent. But in 1893, provoked by the insolence of the company, Lobengula attacked the English. He was terribly beaten; his capital was taken; and in his flight, after ambuscading and annihilating a small force under Major Wilson, he was himself killed. Consult Wills and Collingridge, *The Downfall of Lobengula* (London, 1894). See RHODESIA.

LOBETANZ, lō′be-tänts′. An opera by Thuille (q.v.), first produced in Karlsruhe, Feb. 6, 1898; in the United States, Nov. 18, 1911 (New York).

LO′BITO BAY. A seaport and railroad terminus in Angola, Portuguese West Africa. The town has a good harbor, with deep water to within a few feet of the shore, and a wharf alongside of which ocean-going vessels are able to lie. Its chief importance is as the terminus of the Lobito Bay-Katanga Railroad, which links up with the Cape to Cairo Railroad at Katanga and taps a very rich mining centre in Central Africa. Of the 1200 miles of this system, 224 have been completed and are open to traffic. When completed, this route will shorten the distance from England to Central Africa and Northern Rhodesia by over 3000 miles and this will compel a considerable volume of passenger and goods traffic to flow through the port.

LOB′LOLLY BAY. A North American tree. See GORDONIA.

LOBLOLLY PINE. See PINE (Illustration).

LOB-NOR, lŏb′-nōr′. A lake in Central Asia, situated in the eastern part of East Turkestan, at the northern base of the Altyn Tagh Mountains, and surrounded by the great Central Asian desert (Map: China, F 4). It is the sink of the Tarim, the principal river traversing the desert of East Turkestan. Przhevalski believed that Karakoshun was the shrunken remnant of an expanded Lob-Nor of ancient times; Hedin believed that no change had taken place in either lake during historic times; in 1905 Huntington visited the lake and supported largely the views of Przhevalski. Old Chinese records seem to indicate that a large lake once covered the area. The basins nearest the river contain fresh water, while the farthest sinks are salt, and all are surrounded by marshy, reedy tracts.

LO′BO, FRANCISCO RODRIGUES (?1575–?1627). A Portuguese pastoral writer, of whose life we know practically nothing, except that he was born of noble and wealthy parents at Leiria, where he lived comfortably, and that, after studying the humanities and philosophy at Coimbra, he received his degree of licentiate about 1600. His first book, a small volume of ballads (1596), and his last, a welcome in verse to Philip III (1623), are written in Spanish. Despite the vogue of Spanish during the 60 years of the Spanish rule of Portugal (1580–1640), he wrote all the rest of his works in Portuguese, and thereby exerted a powerful influence upon Portuguese literature. His novel *A Primavera* appeared in 1601 and was continued by a second and a third part known respectively as *O Pastor Peregrino* (1608) and *O Desenganado* (1614). These are considered his best prose works, and they contain some delightful *serranillas* that are among the best poems that he ever wrote. His eclogues in imitation of Camões are weak, whereas his *redondillas* prove that he was at his best when he relied upon native and traditional inspiration. In 1619 he produced an interesting dialogue, *Côrte na Aldêa*, but his epic, *El Condestable de Portugal* (1610), in honor of Nuno Alvares Pereira, the hero of the fourteenth-century struggle of Portugal for independence from Spain, is tame. Consult his collected works (1 vol., Lisbon, 1723; less complete ed., 4 vols., ib., 1774); J. M. da Costa e Silva, *Ensaio biographico critico*, vol. v, pp. 5–112 (ib., 1855), for examination of the works; Friedrich Bouterwek, *History of Portuguese Literature* (London, 1823); I. F. da Silva, *Diccionario bibliographico portuguez*, vols. iii, ix (Lisbon, 1859, 1870), for other biobibliographical information.

LOBO, Jeronimo (1593–1678). A Portuguese missionary to Abyssinia. He was born at Lisbon, joined the Jesuits in 1609, and became professor at the College of Coimbra, where he was teaching, in 1621, when he was sent by his superiors as a missionary to India. He arrived at Goa late in 1622 and in 1624 made a first attempt to get into Abyssinia. Again he set out for Abyssinia in 1625 and carried on successful mission work there for many years. Expelled from the country on the death of the Christian King, he returned to Europe and sought to stir up Spain and the Pope against the Abyssinians. Failing, he went again (1640) to India, where he became rector Jesuit provincial of Goa. In 1656 he was back at Lisbon, where he spent the rest of his life engaged in literary pursuits. He wrote in Portuguese an account of his journeyings that seems never to have been published. In manuscript form, however, it served as the basis for Balthazar Telles's *Historia geral da Ethiopia a Alta* (Coimbra, 1660); and from the manuscript copy the Abbé Joachim Le Grand made his French translation in 1728, under the title of *Voyage historique d'Abissinie*. An English abridgment of LeGrand's edition was made by Dr. Johnson in 1735 and reprinted in 1789.

LOBOC, lō-bŏk′. A town of the island of Bohol, Philippines, situated on the Rio Soca, 4 miles from the south coast and 12 miles east of Tagbilaran. Pop., 1903, 10,756.

LOBOS (lō′bōs) **ISLANDS,** or Seal Islands. Two small groups of rocky islands off the coast of Peru, famous for the great quantity of guano which they contain. The largest island of the northern group, Lobos de Tierra, lies in lat. 6° 29′ S., 12 miles from the mainland, and is about 5 miles long and 2 miles broad; the southern group, Lobos de Afuerra, lies about 25 miles farther south. More than 8,000,000 tons of guano have been exported.

LOBSTEIN, lŏp′stīn, Paul (1850–). A German Protestant theologian, born at Epinal (Vosges). He studied theology at Strassburg, Tübingen, and Göttingen, was appointed a lecturer in the theological faculty at Strassburg in 1876, received a professorship there in 1877, and from 1884 held the chair of dogmatics. His theological views became those of the school of Albrecht Ritschl (q.v.). His publications include: *Die Ethik Calvins* (1877); *Petrus Ramus als Theolog* (1878); *La doctrine de la Sainte Cène* (1889); *Etudes christologiques* (1890–94); *Die Lehre von der übernatürlich Geburt Christi* (1896; Eng. trans., *The Virgin Birth of Christ*, New York, 1903); *Einleitung in die evangelischen Dogmatik* (1896; Eng. trans., *Introduction to Protestant Dogmatics*, Chicago, 1910); *Voltaire et la christianisme* (1901); *Wahrheit und Dichtung in unsere religion* (1904); *Etudes sur la notion chrétienne de Dieu* (1907); *Calvin und Montaigne* (1909); *Quelques enseignements du modernisme* (1911). He also contributed to the *Revue Chrétienne* and to Lichtenberger's *Encyclopédie des sciences religieuses*.

LOB′STER. The largest of crustaceans (*Homarus americanus*), standing at the head of the macrouran decapods. (See Crustacea.) Its allies are the shrimps, prawns, and especially the crayfish. In all of these the head and thorax are united into one region, the cephalothorax, covered by the shield or carapace. The body of the lobster consists of 19 segments, of which the 6 in the abdomen are distinct, while the 13 others, forming the thorax and head, are more or less fused together. There are two pairs of antennæ, a pair of mandibles, two pairs of maxillæ or foot jaws, and three pairs of accessory foot jaws or maxillipeds. The first pair of legs (chelipeds) end in the large chelate or nipper-like claws. The smaller of the large claws (fish claw or quick claw) is slender, toothed, and incurved at the tips, so that lobsters seize fish and shells and grapple with one another. The other claw is thick and heavy, adapted for crushing heavy objects, and is called the club, knobbed, or numb claw. Variations occur in the position of these claws, being either on the right or left side. Lobsters have been observed to transport small stones in their claws while engaged in burrowing. The abdominal legs are, with the exception of the first pair, two-branched and called the swimming legs, or swimmerets. Of these the first pair are slender and not divided in the female, while in the male they are much larger, thicker, and modified to serve as pairing organs, forming when placed together a funnel-like apparatus through which the spermatophores pass into the openings of the oviducts. The last pair of appendages are very broad and are attached to the sixth segment. With the telson or terminal joint (which is not a true segment) they form a swimming organ.

The eyes are large, compound, situated at the end of thick, movable stalks, supposed by some to be homologous with appendages. As to the visual powers of the lobster we know very little. Judging by experiments made on insects with similar faceted eyes, they are probably near-sighted and depend more on perceiving the movements of other animals than clearly distinguishing their definite outlines. The statocyst is a membranous sac indicated by a clear oval space on the upper side of the basal joint of the first antenna, containing a series of delicate feathery hairs arising from a ridge and provided each with a nerve. The wall of the sac is penetrated by a slit through which pass water and minute grains of sand. This was formerly regarded as an ear, but there is experimental evidence that it is an organ of equilibrium.

Little is known with certainty of the senses of taste and smell. Herrick states that the entire body is sensitive, the organs being the soft setæ and the "tegumental glands," these latter being especially numerous on the upper lip. The greatest sensitiveness is in the antennules. Lobsters are sensitive to light and are much more active at night than by day, seeking food or their mates in the darkness.

Habits. The food of the lobster is living as well as dead fish, the usual bait for lobster traps being fresh dead fish. The food is comminuted by the "gastric mill," an arrangement of hard teeth on the wall of the stomach. By a system of "strainers" part is sent into the intestine and part into the liver, digestion taking place in both organs. The intestine opens externally on the underside of the telson. Lobsters are known to live on snails, breaking off the shell of large ones piece by piece and picking out the soft parts, or swallowing small ones whole.

It is known that lobsters are very active and may, if transported several miles from their original habitat, find their way back. Several lots of lobsters marked with a tag were liberated at Woods Hole, Mass., after they were stripped of their eggs. They all moved towards the southwest. One made the journey from Woods Hole to Cuttyhunk, a distance of 12 miles, in three days. One traveled 16 miles in 27 days. Whether this migration is due to the so-called homing instinct, or that they are impelled to seek cooler water, remains to be seen; none moved northward up Buzzards Bay into the warmer waters. As is well known, the lobster can shoot backward to a considerable distance by suddenly flexing the abdomen under the cephalothorax, going, according to Herrick, "25 feet in less than a second."

The geographical range of the lobster is from Henley Harbor, Labrador, at the eastern mouth of the Strait of Belle Isle, southward to Delaware Bay, though stragglers have been found off Cape Hatteras in 30 fathoms and at Beaufort, N. C. They have been captured on the fishing banks of the bays of Maine and Nova Scotia, and have been taken from the stomachs of cod caught on George's Bank. They are usually, however, found near rocky shores below low-water mark to a depth of 10 to 20 fathoms; towards winter they migrate into water from 35 to 40 fathoms deep. They are bottom feeders, never rising more than a few feet above the bottom.

In walking they rest on the tips of the slender legs, extending the large claws forward in front of the head; while the swimming feet aid in progression. They are said to catch the sculpin and sea robin, and are supposed not infrequently to catch other fish.

Reproduction and Breeding Habits. The ovaries (coral) and corresponding male glands are voluminous organs, the testes being white, the ovaries, when the lobster is about to spawn, being dark green, and the ovarian eggs quite distinct. The eggs pass out of an opening on the basal joint of the next to the last pair of walking legs; the seminal ducts in the male open on the basal joint of each of the last or fifth pair of legs. Pairing has never been observed, but it is known to take place in spring and summer. The breeding season is in July and August, though the eggs may be laid in the spring or autumn, and even in winter. The eggs are extruded and carried on the underside of the abdomen, attached by a cement in bunches to the hairs of the swimming legs, the process taking place most probably in the night or early morning. The number of eggs laid is estimated to vary from 5000 to 80,000, and in some cases even to 100,000. The average number of eggs laid by a lobster 8 inches long, when sexually mature and "in berry" or carrying eggs, is 5000; a 10-inch lobster bears about twice as many eggs, and one of 12 inches carries double the number borne by one which measures 10 inches. When the 14 to 16 inch limit is reached there is a decline in sexual vigor. Female lobsters become sexually mature when from 8 to 12 inches in length. The variation in the number of eggs borne by lobsters of the same length is often very great.

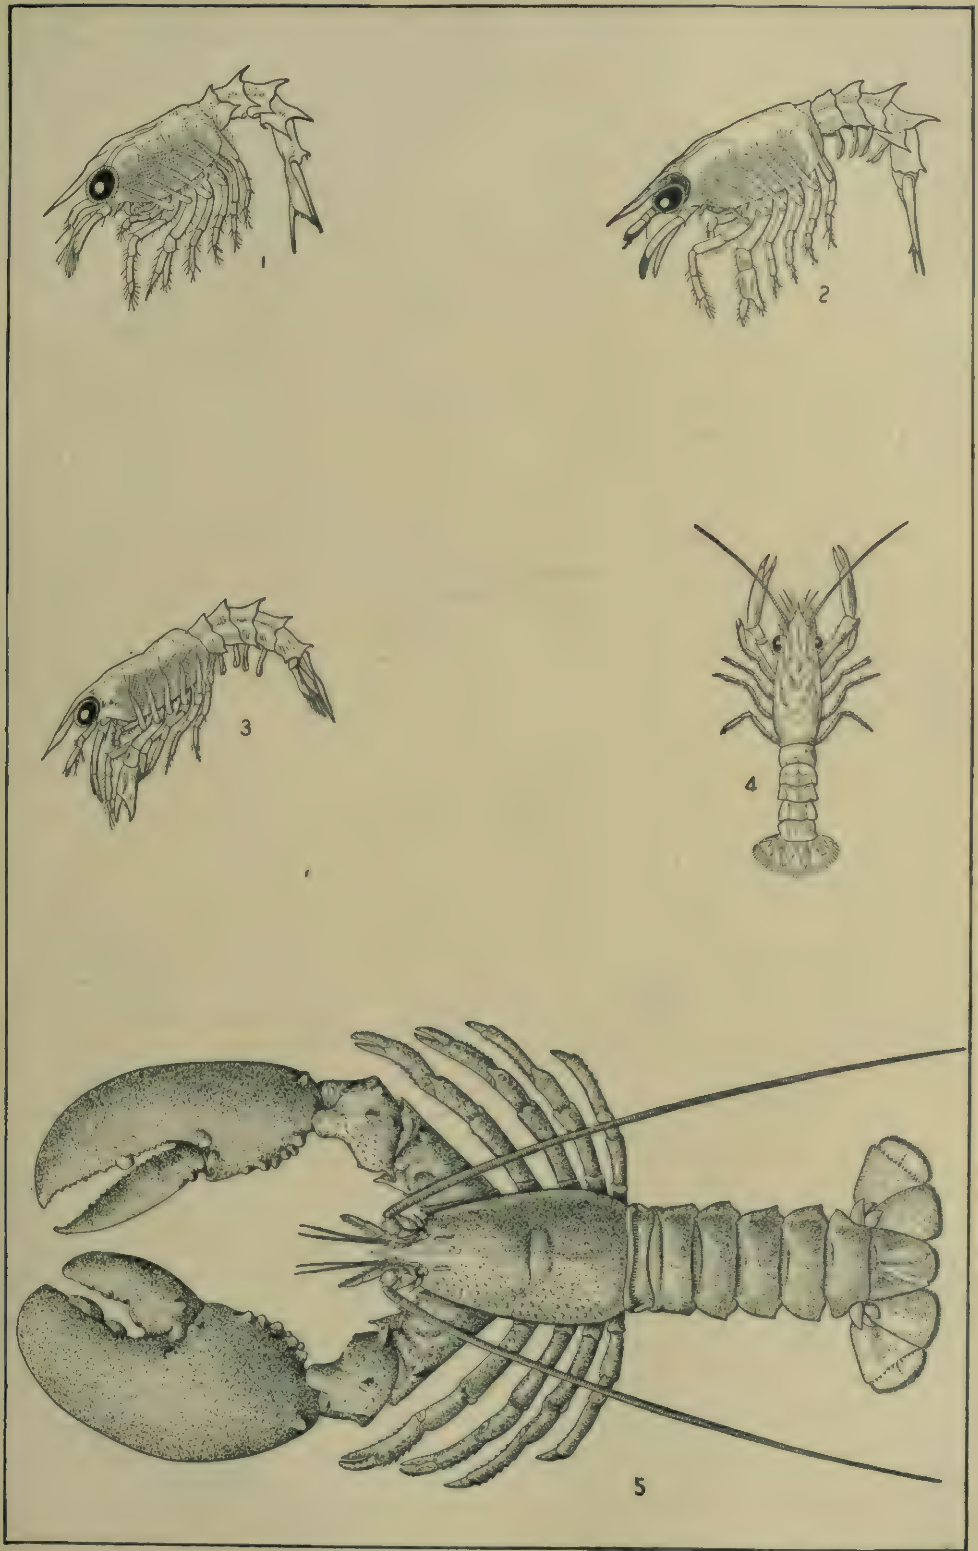
Embryology and Metamorphosis. The lobster has a much shorter larval life than most decapod crustacea, and its development is in fact direct, its metamorphosis being incomplete. The period of incubation at Woods Hole is about 10 months, from the middle of July or August to the middle of the following May or June. In one case the eggs were carried 335 days, from July 1, 1890, to June 1, 1891. The yolk segments in about 24 hours after oviposition, and the embryo passes through the nauplius condition in 10 days, and when from 26 to 28 days old the eye pigment can be seen at the surface. The process of hatching for all the eggs borne by one female requires about a week.

The young on hatching are driven away by the fanning motion of the parent, and in May, June, and July they swim at the surface. During this time and until the fourth stage is reached immense numbers are devoured by surface-swimming fish and other animals. Herrick states that a survival of two in every 10,000 larvæ hatched would maintain the species at an equilibrium, and the destruction of the young under the present conditions of the fishery is probably even greater than this implies. In the first stage (Fig. 1), which lasts from one to four or five days, the length of the body being a little over one-third of an inch (7.84 millimeters), there are no abdominal appendages, and the two pairs of antennæ are short and thick. It now differs, however, from the larva (zoëa) of most shrimps and crabs in having the full complement of thoracic legs. In the second stage, which lasts from two to five days, the length being 9.2 millimeters, four pairs of swimmerets have appeared, and in the third stage the last pair of abdominal legs (uropods) arise. This stage lasts from two to eight days, its body being 11.1 millimeters in length.

In Narragansett Bay (Wickford) the average period for hatching and reaching the fourth stage was a little over 12 days. The length of the fourth stage varies from 10 to 19 days; and during this period the larva is about one-half of an inch (12.5 millimeters) in length.

After the third molt the young lobster or lobsterling (Fig. 4) assumes the shape and habits of the adult. Its body becomes heavier, the chelæ of the first pair of feet are held straight out, and after living at the surface from six to eight weeks it sinks to the bottom, over which it crawls, and now the habits change. The young lobster, previously without

LOBSTER



METAMORPHOSIS OF THE LOBSTER

1, 2, 3, Successive stages in larval development. 4. Young lobster in fully developed form. 5. An old adult.

fear and moving aimlessly about at the surface, now appears timid and retreats from danger, as does the adult; after reaching the bottom it travels towards the shore, burrows in the sand at the bottom under stones, and takes every precaution to avoid its enemies. Its natural food consists of minute crustaceans (copepods), and when food is scarce its own brethren, as it is atrociously cannibalistic.

Molting. The periodical shedding of the skin begins when the lobsterlings are two or three days old and continues throughout life, the intervals between the successive castings of the shell growing longer with age. It molts from 14 to 17 times during the first year of its life. After sexual maturity ecdysis may not occur more than once a year; a 10½-inch lobster has molted from 25 to 26 times.

In the first molts, as in those succeeding, the process is the same, the old skin being split across the back, between the hinder edge of the shield or carapace and the abdomen; the carapace is raised up behind, the body being gradually drawn out through the gaping opening. In adult lobsters the withdrawal of the contents of the big claws is facilitated by the partial absorption of the lime in the shell of the narrow part of the base of the leg, so that the integument can be distended. The muscles at this time are greatly stretched, while their action is probably aided by the removal of water from the blood (Vitzou). During the process the stomach with the solid teeth, as well as the chitinous lining of the œsophagus and intestine, are cast off with the entire integument, including the finest hairs fringing the appendages. "Shedders" are those with shells hard and dull previous to shedding or casting their shell, while soft-shelled lobsters are those which have recently exuviated. The process occupies but a few minutes, unless through weakness it is delayed. The period of shedding is, as in insects and other animals, a precarious one, and sometimes the animal dies during the process; both in the larval and adult stages growth or increase in size takes place while the new shell is being formed, and not immediately after ecdysis (Herrick). The increase in length of a lobster 5½ inches long is 1 inch; in one 11¼ inches long 1¼ inches. The appearance of sudden growth is due to the absorption of water, not cellular growth. After molting it is several weeks before the new shell is as hard as the old one.

Rate of Growth. Our knowledge of the rate of growth of lobsters is not definite, but it is known that this rate varies enormously in different individuals reared in confinement in the same car under apparently the same conditions. Lobsterlings of the same age will measure from 2¾ to 5 inches. It is probable that the length of 9 inches is not usually attained before the fourth year. The variations in growth are so great that "it will never be possible to tell the age of a larger lobster from its length." A 10½-inch lobster is about five years old. The largest recorded lobsters weighed 31 and 34 pounds respectively and were caught off the New Jersey coast in 1897.

Economic Importance. Of the annual yield of lobsters on the Atlantic coast of the United States, 70 per cent is from the waters of Maine. In 1880 the total yield of the United States was over 20,000,000 pounds, and in 1889 this had risen to over 30,000,000, but that was the high-water mark of lobster production. In 1898 it was 14,661,808 pounds; in 1905, 11,898,136; in 1908, 15,279,900; and in 1913 only 12,267,017. But while there has been this immense decrease in amount, the ever-increasing demand has steadily raised the price, so that the value of the catch in 1898 was more than $1,276,000; in 1905, $1,364,721; in 1908, $1,931,100; in 1913, $2,394,822; while in 1889 it was about $860,000. In 1880 the Massachusetts catch was over 4,300,000 pounds, worth about $158,000, or about 3.6 cents per pound; in 1898 it had fallen to less than 1,700,000 pounds, worth less than $148,000, or about 8.7 cents per pound; in 1905 it was 1,283,071 pounds, with a value of $176,234, or about 14 cents a pound; and in 1913 it amounted to 1,524,389 pounds, with a value of $290,423, or 19 cents a pound.

Efforts to maintain the lobster fisheries in an economically valuable condition have been made along two lines: legislation specifying the size that may be legally taken and artificial propagation. A short lobster is one measuring (the usage varying in different States) either less than 9 or less than 10½ inches from the spine on the head to the end of the telson. If caught in traps they must be returned to the water, and it is illegal to have them in possession. The law is difficult of enforcement and probably has little effect on the fisheries. In Massachusetts a recent law allows the taking of short lobsters and provides that female lobsters with eggs attached may be taken, but only on condition that they be sold to the State for purposes of propagation.

Artificial propagation consists in taking the eggs from the female and hatching them in specially devised aquaria, as is done with fish, the larvæ being turned loose in the water. Most of this work has been done by the United States Bureau of Fisheries, who reported that, in 1914, 179,990,000 larvæ were liberated. If the larva is liberated earlier than the fourth stage, it swims at the surface and is very probably eaten by fish; but if liberated in the fourth or later stage, it goes to the bottom and hides under stones or in weeds. Since no satisfactory method was known for keeping the larvæ to the fourth stage, the bureau has been obliged to free them earlier, and it is probable that much of this work has been of no value. Important experiments on rearing the young lobster have, however, been conducted by the Rhode Island Fisheries Commission and have demonstrated the possibility of carrying them to the fourth stage in sufficient numbers to be commercially practicable. It seems probable that application of these methods will result in a permanent improvement in the fisheries. Lobsters are caught chiefly by means of traps made of laths and stout cord, into which they are beguiled by a piece of meat or fish. These traps are usually 3 or 4 feet long and capable of containing a number of lobsters. They are set in water ranging from 5 to 6 up to 30 fathoms or even more, and are visited every two or three days, if the weather permits. From the traps the lobsters are taken to floating cages, called cars, where they are kept until enough are gathered to warrant a shipment.

Bibliography. H. C. Bumpus, "The Embryology of the American Lobster," in *Journal of Morphology*, vol. v (Chicago, 1891); F. H. Herrick, *The American Lobster: A Study of its Habits and Development* (Washington, 1895); A. D. Mead, *Method of Lobster Culture* (ib.,

1910); F. H. Herrick, *Natural History of the American Lobster* (ib., 1911); E. W. Barnes, *Methods of Protecting and Propagating the Lobster, with a Brief Outline of its Natural History* (rev. ed., Providence, 1911).

LOB′WORM′ (from *lob*, probably from Welsh *llob*, dolt + *worm*), or Lugworm. A chætopod worm (*Arenicola piscatorium*), used by British anglers as a bait. It lives in deep burrows hollowed out of the sand on the seashore, eating its way and passing the sand through the alimentary canal to extract whatever nutriment it may contain. It has a large head without eyes or jaws, a short proboscis, and 13 pairs of gills, placed on each side of the middle of the body. It reaches a length of nearly a foot. Another species (*Arenicola cristata*) is found on the coast of eastern North America, and others on the Pacific coast.

LOCAL ACT or **STATUTE.** A legislative enactment which is made applicable only to a subordinate area or division of a state, as a given county, city, or town. An act or statute applying to the whole state is known as a *general* act. See Act; Statute; Legislature.

LOCAL ACTION. See Voltaic Cell or Battery.

LOCAL′ITY, Perception of. All perceptions are more or less definitely localized. Our visual perceptions occupy positions in space; when we are touched upon the skin we perceive a pressure localized on the surface stimulated; we are able to describe the position of our limbs while they are concealed from our view; taste and thirst are localized in the mouth; even odors and sounds are localized in space, though with less immediacy and definiteness than other perceptual stimuli. Furthermore, we are able to say, not only that a stimulus occupies such and such a position in the field (absolute localization), but also, and especially in the case of visual and cutaneous perceptions, that the stimulus occupies a position relative to other stimuli in that field (relative localization).

Our various modes of perception differ greatly as regards these two kinds of localization. In visual perception we habitually localize stimuli with reference to other stimuli in the field, and relative localization is highly developed. The ability to discriminate the difference between points in space is measured in terms of the visual angle or the distance between the two retinal images; and experiments show that we can distinguish such a difference in the transverse plane when the two retinal images are about .004 millimeter apart (visual angle about 1′). Discrimination in the median plane, relative discrimination of depth, is possible when there is a difference of 5″ in the position of the retinal images of the two eyes. If, however, a single point is set against a uniform background it is localized as distant, but with considerable error. When we turn to the cutaneous perceptions we find the matter reversed. The absolute localization of a pressure on the skin, although it varies with the part stimulated, is fairly accurate; e.g., on the wrist the average error of localization is from 5 to 10 millimeters. But if we stimulate the skin with two points, commencing with a separation of 1 millimeter, and gradually increasing it by small steps, we find that the two points are at first perceived as one; then, with greater separation of the stimuli, as a circle; then as a thickish line; then as two circles connected by a line; and finally as two discrete points. The two points are now perceived as different; yet their relative position, in the longitudinal or transverse direction, is not perceived until the difference between the two stimuli is still further increased. It is apparent, therefore, that the relative localization of two points is not so highly organized in cutaneous perception as is the case in visual perception. The two-point limen (see Extension; Limen) for pressure varies at different regions of the cutaneous surface; it is smaller than that for cold or warmth. If we isolate pressure spots, and determine the distance at which they are perceived as two with simultaneous stimulation, it is found that the separations are smaller than the usual two-point limens: the value for pressure spots on the back of the hand has been found to be 0.3 millimeter, upon the forehead 0.5 millimeter, upon the chest 0.8 millimeter, and upon the back 4 millimeters. The values for cold spots in the same cutaneous areas were 2, 0.8, 2, and 1.5 millimeters; for warmth, 3, 4, 4, and 4 millimeters. The movement limen, or the least noticeable difference in the position of a limb, depends upon the joint in which the movement takes place. The larger joints have, as a rule, the smaller limens; the hip is noticeably more sensitive than the ankle (0.5° and 1° respectively). Recent experiments on the localization of sensations within the body show that mechanical and electrical stimulations of the œsophagus are in general referred either to the region below the sternum or to the throat, and that pressures in the stomach are localized within the trunk but at points below the actual position of the stomach.

In all these instances the perception is effected by way of secondary criteria—visual imagery, movements towards the part stimulated, the touching off of a verbal response, etc. The question now arises: How can we account for this unequivocal relation? How does it happen that a touch upon the back of the hand, when the eyes are closed, arouses just the visual idea of this part of the skin and no other, just the particular name of this cutaneous area, or just the one special movement? Historically, the most noteworthy answer to this question is Lotze's *theory of local signs*. It is supposed that every cutaneous sensation has, in addition to its specific quality (pressure, warmth, etc.), a peculiar qualitative coloring which is the sign of its locality. It is pointed out that the skin differs in structure at different parts of the body—"now covered by a thick and now by a delicate epidermis; now spread over a cushion of fat, now passing over bone or muscle." These differences, however, are of a sort to condition differences in the intensity, rather than in the quality, of the impression. Moreover, if we take two symmetrical areas, e.g., the backs of the right and the left hands, where the anatomical conditions are very similar, a unilateral stimulation is immediately localized as right or left; whereas, on the basis of the theory, localization should be difficult. Lastly, observation reveals no qualitative difference of impressions that could serve as basis for local signature. Hence we must probably regard the secondary criteria themselves as local signs, and must believe that they are the product of long development in the history both of the individual and of the race. Visual, cutaneous, and articular sensations appear to possess the attribute of extent (q.v.), and this gives us a starting point. Our vision is, further, (1) binocular, and the fusion of the two monocular fields gives us the indefinite perception of depth; (2) the eyes are constantly moving, so that associations are set up between visual sensations and the sensations from the muscles of convergence and accommodation; (3) and finally, such secondary criteria as the distribution of light and shade, linear perspective, aërial perspective, etc., furnish cues to nervous habits which are immediately realized in the perception of locality. A similar process obtains in the case of cutaneous sensation: we are moving organisms, and the transition from bidimensional to tridimensional space is doubtless facilitated by the organism's ability to move and fold the skin upon itself—by the crossing of arms and legs, the exploration by the hand of an object held to the breast, etc. Definite associative tendencies are thus set up between pressures, warmths, colds, and muscular sensations, and again between these and visual sensations.

There remains to mention the secondary spatial localization of odors and sounds. That of odors is vague and uncertain; we turn the head in the direction which affords the most intensive perception, and we refer the position of the stimulus to that direction. The localization of sounds is more accurate; the most important clew is the inequality of the intensity of the sound as heard by the two ears, so that the greatest errors of localization occur when the source of the sound lies in the median (sagittal) plane. Two other factors, of less importance, are the absolute intensity of the sound and its complexity: the tones of musical instruments, noises, etc., are localized with greater accuracy than are pure tones.

For a more detailed account of the perception of locality in the third dimension, see DISTANCE or DEPTH. Consult: R. H. Lotze, *Medizinische Psychologie* (Leipzig, 1852); Oswald Kuelpe, *Outlines of Psychology* (New York, 1909); E. B. Titchener, *Text-Book of Psychology* (ib., 1910); W. Wundt, *Physiologische Psychologie* (Leipzig, 1910–11); G. T. Ladd and R. S. Woodworth, *Elements of Physiological Psychology* (New York, 1911).

LOCAL OPTION. A system of local control of the liquor traffic. See TEMPERANCE.

LOCAL RANK. A temporary rank or grade bestowed in the British army, during war, which permits an officer of junior absolute rank to perform duties of a much higher or relative rank. The rank is temporary and holds good only in that army, commanded at the time by the commander in chief who grants it, but must be confirmed by the Secretary of State for War.

LOCARNO, lô-kär'nô (Ger. *Luggarus*). A town in the Canton of Ticino, Switzerland, on the north shore of Lake Maggiore (q.v.) at the mouth of the Maggia (Map: Switzerland, C 2). It is connected by a branch railway with the main line of the St. Gotthard system and by regular steamboat service in summer with Arona (q.v.). The pilgrimage church of Madonna del Sasso contains paintings by Bramantino and Ciseri, and on September 8 occurs the great festival of the Nativity of the Virgin. It has manufactures of brushes and candles. Locarno, mentioned in history as early as 789, came into the possession of Milan in 1340 and was ceded to the Swiss in 1512. Its development was arrested by the expulsion of the Protestants in 1553. Pop., 1910, 5638 (mostly Catholic Italians).

LOCATELLI, lō'kȧ-tĕl'lē, PIETRO (1693–1764). An Italian violinist and composer, born at Bergamo. All that is known of his life is that he studied in Rome under Corelli (q.v.) traveled considerably, and finally settled in Amsterdam, where he established regular concerts. He is important not only in the history of the sonata, but also in the development of the violin technic towards real virtuosity. His works consist of numerous concertos and sonatas.

LOCH, lŏk, HENRY BROUGHAM, first BARON (1827–1900). A British colonial official, born at Drylaw, Midlothian. He entered the navy in 1840, but in 1842 was gazetted in the 3d Bengal Cavalry, and he served throughout the Crimean War. He joined Lord Elgin on a special embassy to China in 1857, to Japan in 1858, and again to China in 1860. On the last occasion a terrible imprisonment which he suffered at the hands of the Chinese nearly cost him his life. He served as Governor of the Isle of Man in 1863–82, as Governor of Victoria in 1884–89, and as Governor of Cape Colony and High Commissioner of South Africa in 1889–95. In South Africa he supported Cecil Rhodes's policies; annexed Mashonaland and Matabeleland; and opposed President Kruger of the Transvaal in many disputes. But he did not favor strong measures against the Boers, and this led to his return to England, where he was made a peer.

LOCHABER (lŏk-ä'bẽr) **NO MORE.** A song by Allan Ramsay, first published in his *Tea Table Miscellany*, a collection of English and Scottish songs. The air, for which a Scottish origin has been claimed, is probably Irish and appears as "The Irish Inne" in Thomas Duffet's *New Poems, Songs, Prologues, and Epilogues* (London, 1676). It was also known as "King James's March to Dublin." The melody is attributed in Bunting's *Ancient Music of Ireland* to Myles Reilly of Killincarra, about 1635. Consult *Our Familiar Songs* (New York, 1901).

LOCH EARN. See EARN.

LOCHES, lôsh. An ancient town in the Department of Indre-et-Loire, France, situated on the left bank of the Indre, 29 miles southeast of Tours (Map: France, N., F 5). Its chief point of interest centres in the old castle built by Charles VII and now used for administrative purposes. One of the towers still contains the iron cages which held many famous prisoners during the reign of Louis XI. The castle also contains the tomb of Agnes Sorel, the mistress of Charles VII. Here James V of Scotland was married to Madeleine of France in 1536. The town hall, a Renaissance building of the sixteenth century, and the collegiate church of Saint Ours (tenth to twelfth century) are also noteworthy. Loches produces textiles, liquors, and leather, and trades in agricultural products and horses. It is supposed to occupy the site of a Roman settlement. Pop., 1901, 5161; 1911, 3946.

LOCH GOIL. See GOIL, LOCH.

LOCHIEL, lŏk-ēl'. A Highland chief of Scotland. See CAMERON, DONALD.

LOCHIEL'S WARNING. A poem by Thomas Campbell, the subject of which is Donald, son of Sir Evan Cameron of Lochiel.

LOCHINVAR, lŏk'ĭn-vär'. A well-known ballad, and the name of its hero, in Scott's *Marmion*.

LOCH KATRINE, kăt'rĭn. See KATRINE, LOCH.

LOCHLEVEN. See LEVEN, LOCH.

LOCHLEVEN CASTLE. See Leven, Loch.

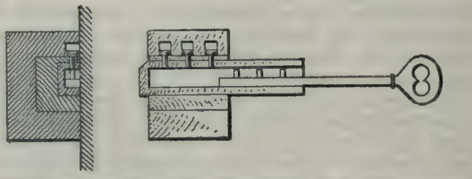
LOCH LOMOND, lŏ′mond. See Lomond, Loch.

LOCHNER, lôG′nẽr, Stephan (?–1451). A German painter, the chief master of the Cologne school. He was born at Meersburg, on Lake Constance. Nothing is known of his training, and little of his life. He came to Cologne about 1426, youthful but already trained, and soon gained great influence over the local school. He is first mentioned in the city records in 1422 and was chosen councilor of the Guild of Painters in 1447 and again in 1450. His earliest-known commission was the fine triptych of the Last Judgment, the central panel of which is in the Cologne Museum, the wings in the Frankfort and Munich galleries. But his masterpiece—and that of the Cologne school—is the triptych known as the Kölner Dombild in Cologne Cathedral. It was not only the greatest work of its day, but one of the finest, if not the finest, of its kind ever painted in Germany. The central panel represents the "Adoration of the Kings," the right wing "St. Ursula with her Maidens," the left, "St. Gereon with the Theban Legion." It was originally painted for the chapel of the Town Hall, where it was seen by Dürer, who mentions it in his diary. Other extant paintings by him are two tablets, each representing three saints, in London and Cologne respectively; "The Madonna with the Violets" (Archiepiscopal Museum, Cologne); the "Madonna in the Rose-Arbor," in the Wallraf-Richartz Museum, Cologne; "Christ and Six Saints," in the Germanic Museum of Nuremberg; and "The Presentation in the Temple" (Darmstadt). The spirit of Lochner's radiant and serene art is essentially Gothic, inspired by a profound religious sentiment. His color is wonderfully brilliant yet soft, his figures dignified and charming, his grouping excellent; but his draftsmanship, especially in the rendering of arms and hands, is often defective. Consult Carl Aldenhoven, *Geschichte der kölner Malerschule* (Lübeck, 1902), and Mela Escherich, *Die Schule von Köln* (Strassburg, 1907).

LOCH TAY. See Tay, Loch.

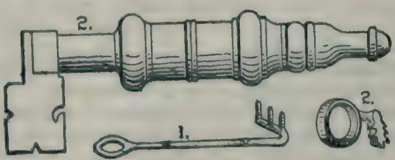
LOCK (AS. *lōc*, from *lūcan*, OHG. *lūkhan*, Goth. *ga-lūkan*, to close; ultimately connected with Lith. *lúzti*, Skt. *ruj*, to break). A contrivance for securely fastening a door, drawer, lid, or other moving part, by means of an inclosed bolt which is shot back and forth by a key or other device to engage with some form of staple, plate, or box. The bolt is usually guarded by an obstacle which must be overcome by the action of the key. Key locks may be divided into two general classes according to the character of the obstacle. 1. *Warded locks* are those in which the obstacle consists of fixed wards or ridges within the lock which prevent the turning of the key unless its grooves or perforations coincide with the wards of the lock. 2. *Tumbler* or *lever locks* are those in which the obstacles are movable levers or pins which must be moved to a certain position before the bolt can slide. In this class of locks the bolt can be actuated only by a properly shaped key, whose indentations, or "bittings," will raise the levers or pins exactly to the proper height. Modern locks include also combination or dial locks, chronometer or time locks, and various kinds of small "keyless" locks. None of these have keys.

Historical Development. Early in the history of civilization wooden bars or bolts were the first means employed to protect crude doors, and from them was developed the primitive lock, which with some means or other for controlling it—or, in other words, a key—we find referred to frequently in ancient literature such as the Odyssey and the Old Testament. Such a device as used in Nineveh actually has been found in one of the palaces of Khorsabad, with a key resembling those still employed in the East. In an ancient Egyptian lock, which figures in the illustration, one may find the fundamental idea of the modern pin-tumbler lock. Here the wooden bar or bolt of the lock was held in closed position by movable pins, which fell from the case into corresponding holes in the bolt, and the latter could not be moved until a key with pegs corresponding to the holes was inserted, and the pins raised up in their housing so as to remove them from the holes in the bolt and permit the sliding movement of the latter. Such a pin lock was common with many nations of antiquity, as were also locks which employed a curious hooked-shaped key, and they are described or illustrated in various ancient records.



SECTIONS SHOWING THE PRINCIPLE OF THE EARLY EGYPTIAN LOCK.

Early Greek and Roman doors were held together by devices partaking of the nature of simple fastenings rather than locks, but at a later period these mechanical contrivances had become essentially locks with keys. Sometimes these keys were supplied with wards, but no Roman or other earlier lock appropriate for such keys ever has been brought to light. In Great Britain old keys have been found, indicating locks of more or less elaboration, but none of the locks until the Middle Ages has survived.

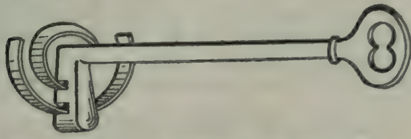


(1) EARLY EGYPTIAN AND (2) POMPEIAN KEYS.

At a period that cannot be accurately determined, there was devised or, at any rate, constructed on a practical basis, the warded lock, where a fixed obstacle was introduced in the case to stop and prevent the movement of a key, unless the latter was correspondingly cut away.

Almost contemporaneous with the early warded lock was the so-called puzzle or letter lock, often employed in the form of a large lock without a key, where various arrangements of dials were made so that once closed the same arrangement of its elements had to be observed to open it. This principle was not peculiar to any one nation or continent, as puzzle locks are to be found not only in Europe but among Russians, Chinese, and Hindus.

Warded Locks. The use of wards was devised in order to prevent any key of the same size opening a lock and to render difficult the use of false keys. In warded locks a special shape of keyhole was employed, and ridges of iron were placed in circles or parts of circles in the casing, so that the only key that could be turned in the lock, once it had entered the case, would be one having proper grooves or clefts cut in the end of the bit or projection at the extremity, so as to pass over or by these ridges. The origin of the use of wards goes far back in the art of lock making, and mediæval locksmiths evolved complicated structures which, however, could not resist master keys, picks, or skeleton keys in the hands of a skillful workman, especially where an impression was made on wax or tallow on the bit, or lock end, of the key, as in this way the presence and nature of the wards could be indicated, and keys that would fit readily could be made.



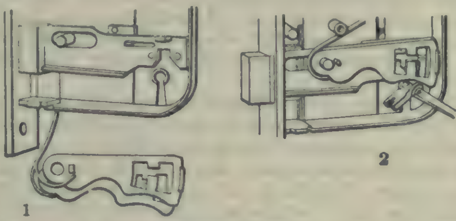
EARLY FORM OF WARDS FROM WARD LOCK.

In the exquisite work of mediæval locksmiths many keys were made where the perforations had no relation to the working of the lock, and with the latter were often combined secret escutcheons and more or less complex and artistic devices. Although increasing the number of wards rendered picking more difficult, and multiple locks were placed on the old strong boxes, making them truly complex, yet indeed they were most simple to open from the standpoint of the modern lock expert.

Up to the end of the eighteenth century, however, warded locks were considered safe, and for ordinary uses they were the only type generally employed up to the beginning of the nineteenth century, even for important purposes, and they still are in use in the cheapest form of locks, as found in ordinary furniture.

In any warded lock the essential element is a bolt made with a notch or hollow, known as a talon with which the key engages, with a back spring attached to hold the bolt in the place to which it is moved by the key. A back spring is found in most warded locks, so that the feeling to the manipulator is much the same as in a lever lock, but it gives little increase in security. The bolt is moved forward or backward by the revolution of the key, turning on a pivot if a barrel key, or with the end of it resting and revolving in a hole if of solid design. The action of the key is regulated by the length of the bit or projection at its extremity which engages the bolt, and the depth of the notch cut in the lower side of the bolt. As the wards permit only a key with corresponding openings to revolve, it is only by such a key that the bolt may be moved, and no other key of the same size will avail. The bolt has at the end opposite to that which enters the staple or face plate a small slit open to form a spring, and below are two notches divided by the grooved curve in the bolt. When the key enters and is turned around, it draws the bolt forward or backward in locking or unlocking, and the spring causes the bolt to drop into one of the notches or rise up along the groove according to the distance by which it is moved.

Tumbler or Lever Locks. The tumbler or lever lock was an advance upon the warded lock just described, as in this form one or more metal pieces, known as tumblers, levers, or latches, intercept the bolt and prevent it from being shot until they are raised or released by the action of an appropriate key. In its simplest form the tumbler or lever lock consists of the bolt, and one or more levers or tumblers which are pivoted so that they may be raised to a height depending on the clefts in the bit of the key, the end portion of which serves to move the bolt as in the warded locks. In any tumbler or lever lock the appropriate part of the bit of the key therefore must reach and raise each tumbler or lever as well as move the bolt, so that there are two elements to enforce safety, disregarding a combination with wards which is always possible. There are two typical forms of tumbler or lever locks—one where a post or stump on the bolt moves through a gating or passage between two notches in the lever, as in the illustration, and the other where the post is on the tumbler and must be raised from one to the other of two notches on the bolt. The form with the gating in the lever is now more usual and is found on many ordinary door locks, so that a description will serve to illustrate the principle of locks of this class as well as simpler locks found in ordinary uses.

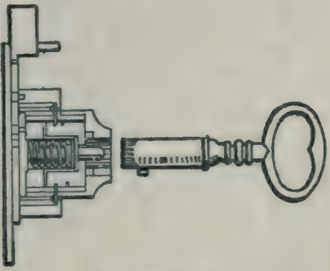


TUMBLER LOCK.

1, bolt in place, tumbler removed, and shown below; 2, tumbler in place with key being turned to lift it.

The bolt which secures the door has on its underside the talon or notch with which the key engages, while it also carries a post which, when the lever or levers are raised, can pass through the opening or gating between the two notches of the lever, which are exactly as far apart as the distance moved by the bolt. The lever or levers, which vary from one to five or six in number and are behind the bolt, are a series of small plates mounted on a pivot and usually fitted with a spring so arranged to move with regard to the post on the bolt that the latter cannot be moved until the tumblers are lifted enough to cause a clear passage through of the gating for the post as it is moved from one notch to the other. The levers are cut of different height, so that the key, by means of its various clefts, must lift all the gatings to the same height and furnish a clear path for the post. The particular cleft or notch of the key on which each lever rests accordingly raises its appropriate lever, so that when a number of levers are used the gatings of all will coincide. It is obvious that, by increasing the number of tumblers or levers as well as employing variations of the arrangement of a given set, the lock can be complicated to an almost endless extent and the security correspondingly increased.

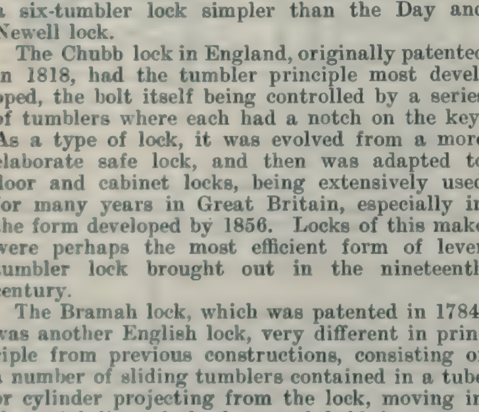
This type was considerably improved during the first half of the nineteenth century, and naturally these locks were elaborated and made with care and skill for various purposes, such as for bank vaults and fireproof safes, and with exquisite workmanship there were combined ingenious modifications, though the results in the way of new principles have survived in modern practice in but few instances. Among the devices employed at this time were detector locks, where once a key was inserted in a lock it was retained, or some device indicated that the lock had been tampered with. In the United States Andrews made a lock with a series of tumblers and a detector and also a disk or snail-wheel lock, while Newell of Day and Newell made a lock with a double set of tumblers, one to receive motion from the other. Hobbs introduced a six-tumbler lock simpler than the Day and Newell lock.



BRAMAH LOCK.

The Chubb lock in England, originally patented in 1818, had the tumbler principle most developed, the bolt itself being controlled by a series of tumblers where each had a notch on the key. As a type of lock, it was evolved from a more elaborate safe lock, and then was adapted to door and cabinet locks, being extensively used for many years in Great Britain, especially in the form developed by 1856. Locks of this make were perhaps the most efficient form of lever tumbler lock brought out in the nineteenth century.

The Bramah lock, which was patented in 1784, was another English lock, very different in principle from previous constructions, consisting of a number of sliding tumblers contained in a tube or cylinder projecting from the lock, moving in the axial line of the key, and held in contact with the latter by the pressure of a spiral spring. For ordinary purposes this lock was very secure, and as it was developed and improved it marked a more scientific advance in the art of lock making than any other lock made up to its time. Simpler methods and less expensive methods of manufacture were found to serve equally well, and for this reason the Bramah lock did not gain a permanent place.



YALE PIN-TUMBLER LOCK.

1, without key; 2, key inserted, pins brought into line, and bolt being turned.

In the United States numerous inventions were made, among which was the Parautoptic lock of Day and Newell. It was an ingenious and complicated piece of mechanism, which was widely used for some time after its introduction and up to 1850 considered absolutely safe. All of these types of locks could be picked in one way or another, and it was soon realized, as has since proved true, that any lock with an open keyhole, no matter what its interior construction, could be opened, given a workman of requisite skill, the necessary tools, and the available time.

Pin-Tumbler or Cylinder Locks. As an improvement on the lever or tumbler lock, came the pin-tumbler or cylinder lock, first brought out about 1860. It was invented by Linus Yale, Jr. (q.v.), and United States patents covering the invention were issued on Jan. 29, 1861, and June 27, 1865. It was essentially a development of the old Egyptian pin lock and was the first to employ a small flat key in place of the heavier and massive keys previously used. Soon, however, the flat key was found to be available for lever locks also, so that eventually many locks employing such a key came into use, some of which were frequently, but erroneously, referred to as Yale locks, a name which only properly applies to a lock made by the Yale and Towne Manufacturing Company.

The pin-tumbler lock consists essentially of a cylindrical shell or case containing a barrel or plug placed eccentrically, which being rotated acts to move the bolt of the lock through the agency of a cam at its inner or rear end. Unless the appropriate key is inserted in a slot or keyway extending longitudinally through the plug, the latter is prevented from being turned by five divided pin tumblers which are free to move up and down in little round holes or cylindrical chambers extending through both the lower part of the case or cylinder and down into the plug, as shown in the illustration. The upper parts of these pin tumblers or drivers are forced by springs down on the lower and corresponding parts or tumblers proper in each set of holes, when both sets of holes are in line, so that when the key is not inserted in its slot in the lock, the case and plug are held fast together and the latter prevented from being revolved with respect to the inclosing cylinder. Now, when the proper key is inserted, the lower pins, which normally rest at the lower part of the respective pin chambers and intersect the keyway, though not extending to its bottom, are forced up in their chambers, and where they are of such height with respect to the notches of the key that, when resting on the appropriate notches, their upper extremities terminate at the joint between the plug and the cylinder, the former can be rotated. As the lower extremities of the drivers must also terminate at this surface, the plug is free to rotate, since none of the pins then engage both it and the casing. Of course the revolution of the plug through the cam at its rear acts to slide the bolt, and this can occur only when the proper key is inserted, because otherwise some of the pins would be raised too high and others too low, so that the plug would still be locked, either by the upper pins falling below the boundary surface or the lower pins rising above it, and would not revolve. A variation of as much as $\frac{1}{50}$ of an inch from the true height or position in any one of the five pin tumblers usually found in a cylinder lock is sufficient to prevent the rotation of the plug in the cylinder.

The thin flat key first introduced by Linus Yale, Jr., was soon extensively applied to other types of locks, and later other forms of keys and of keyways in the plug of the pin-tumbler lock were developed, especially those known as the corrugated, the ribbed, and the paracentric. While the pin-tumbler construction offered great security by reason of the great number of permutations it permitted, neither it nor even its improved forms were absolutely secure against picking at the hands of an expert with proper tools. Greatly increased safety was secured by forming the sides of the keyway in the plug with opposing corrugations, interlocking with those of the key, thus rendering picking much more difficult, in addition to putting on the market an entirely new series of locks and keys. This device also prevented the tilting of the key in the plug and rendered its manipulation more convenient.

In the corrugated form the corrugations did not extend beyond the axial line of the keyway, so that picking the lock, while difficult, yet was possible. Accordingly this key in turn gave place to the paracentric key, where the keyway was constructed with continuous longitudinal barriers in planes parallel to the motion of the key, projecting from opposite sides of the keyway past its centre or axial line, which made an interlocking so intricate as practically to preclude the use of picking instruments to operate vertically on the tumblers. Such a key can be constructed only with special reference to the class of lock it is designed for. This type of lock represents the greatest security achieved in any form of lock having a keyhole, and has found application in locks for all purposes.

Master-Keyed Locks. Such locks are an important consideration in hotels, in office buildings, in locker rooms, and even in private houses, as it is possible to arrange a system of keys whereby a master key will control all the locks of the house with the appropriate subpass keys of more limited action down to the single keys for an individual lock. In modern lock construction different sizes and styles of locks can be brought under the control of a single master key. One arrangement of masterkeyed lock is to have two settings or changes, one uniform and the other different. A pin-tumbler lock may be master-keyed by cutting each pin in two places or by providing a second annular plug, while a duplex lock may have two sets of pin chambers, either one of which will operate the bolt.

Dial or Combination Locks. A dial or combination lock, as used on American fireproof and burglar-proof safes, is one which requires no key and consists of a bolting mechanism employed to check the heavy bolt work of a safe door, thus making it impossible to move the bolts except when duly released by the appropriate combination. In this type there is a set of changeable tumblers or wheels actuated by a spindle, passing through the door of the safe, and having a graduated dial on its outer end. By means of this the spindle can be rotated so that the tumblers can be set and the bolting mechanism released to act. Dial locks are made in two essential grades, the first for burglar-proof safes, in which the construction is heavy, elaborate, and designed to resist violence, such as the action of high explosives, while locks of the second grade, which are smaller, are intended merely for fireproof doors and are not designed to resist great violence. The dial locks used on bank vaults and burglar-proof safes may be capable of as many as 100,000,000 changes of combination. They are practically unpickable.

Dial locks of small size, commonly called "keyless" locks, are found useful in various places to obviate the use of a key, as in gymnasium and armory lockers, bathhouses, and for similar purposes where such locks are convenient, because obviating the necessity of the person exercising or bathing being troubled with a key.

Time Locks. The combination lock in its application to safes and vaults did not remove the danger of the human element, for a person acquainted with the combination and having access to the vault at unauthorized hours might open its doors or could be compelled by threats or force to reveal the combination to a burglar. Accordingly the time lock was added to the combination lock for the protection of bank and safe-deposit vaults. Clockwork in connection with a lock had been patented in Great Britain in 1831 by Rutherford, and in 1836 an alarm lock was patented by Meighan; but the use of clock mechanism to release the levers did not find practical use until about 1875, and even to-day such use is confined almost exclusively to the United States and Canada, although a few American time locks are found in the various foreign countries, especially in England.

In the time lock the locking mechanism acts by clockwork, which usually is in the form of two or more chronometer movements of the finest construction, three or four being employed in the largest and most elaborate constructions. These movements are in multiple, so that the failure of one will not prevent the unlocking of the safe door during predetermined hours for which the clockwork is set, with a special attachment for Sundays and holidays. The time lock serves merely to release the bolt-operating mechanism, which usually is quite heavy and is also guarded by one or more combination locks. The bolt work may be operated by hand through the agency of a spindle or by an automatic bolt motor. This last device, used in connection with a time lock, is a mechanism attached to the inside of a safe door and containing heavy springs, which are set or compressed while the door is open, and which when released by the action of the time lock are capable of automatically retracting the heavy bolt work of the door, whose outer surface is absolutely unbroken and therefore as strong as any other part of the safe, and there is no communication between the interior and exterior. A further protection sometimes employed consists in an electromagnetic device which guards the automatic mechanism until released by closing the proper circuits at a keyboard.

The importance of the lock on a safe-deposit or bank-vault door can be estimated by considering it in connection with such a door as that of the vault of the J. P. Morgan & Co. building built in 1914 in New York City. This door is 9 feet in diameter, with a thickness of 45½ inches, in the form of massive armor plate, and weighing with its vestibule 120 tons. The door is held by a series of 5-inch bolts, which are controlled by two combination locks, and these in turn by time locks with four clock movements, any one of which will permit the opening of the combination locks and thus release the door.

Safe-Deposit Locks. Within the safe-deposit vault itself the individual safes and boxes of the customers require a special form of lock in order to secure the greatest safety. The usual type is a key lock provided with a guard lock, the key of the latter being kept by the custodian of the vault and common to all of the safes in the vault. Each lock has an individual or change key unlike any other in the vault, but which will not open its lock until the guard key has been inserted and turned, thus making the presence of the custodian absolutely essential to the opening of a box. Various types of improved lever-tumbler or pin-tumbler mechanisms are provided for these boxes, and if the box is very large a dial lock may be used. See SAFES AND SAFE-DEPOSIT VAULTS.

Keys. In olden times keys were ponderous affairs, which were borne on the shoulder instead of being tucked away in the pocket. The modern key, which has been developed to a point where it is as small as possible for its function and for necessary strength, consists of three parts—the bow, or upper end; the bit, or lock end; and the connecting shank. When the cuts or notches of the bit are on the side or edge, they indicate a tumbler or lever lock; when the cuts are on the top or bottom, the key belongs to a warded lock. When the shank is tubular, or, in other words, belongs to a barrel key, it indicates a lock which can be operated from one side only, such as are used for cupboards, drawers, and chests, while door-lock keys have solid shanks and will operate the lock from either side, this form being usually known as round keys. Such keys may be made of cast iron, of malleable iron, or of bronze or brass, and also may be built up of several pieces. A solid steel key, however, is the best of this class.

Cylinder locks at first had flat keys. This form of key, with or without a wing or bit, was soon found available for lever-tumbler and warded locks. Subsequently to render more difficult the introduction of picks into the pin-tumbler lock, the key and its plug, as we have seen, were corrugated, and finally modern Yale locks, i.e., those made by the Yale and Towne Manufacturing Company, have what is known as a "paracentric" instead of a flat key.

Classification of Locks. Locks in a general way may be classified according to the uses for which they are intended. Those used in the construction of buildings are classified as *Builders' Locks* and include numerous types, in many of which with the dead-bolt or night-latch mechanism there is combined a latch bolt operated by an ordinary door knob. Mortise locks are those intended to be mortised into the door, while rim locks are designed for attachment to its surface.

Cabinet Locks.—Cabinet locks, such as are found in furniture and cabinetwork generally, differ from builders' locks and often constitute a separate industry, affording scope for interesting artistic designs for their escutcheons, plates, and knobs, rather than complex mechanical construction. Under this head may be classed drawer or till locks, wardrobe locks, chest and box locks, desk locks, and literally hundreds of types designed for specific purposes. Just as for doors, so for cabinetwork the pin-tumbler type is the best, and various forms of keys may be used.

Other classes of locks, whose uses are explained by their titles and which show in each class many types, are trunk locks, prison locks, asylum locks, and padlocks. These are described in the catalogues of the leading manufacturers.

Lock Controversies. In 1851, at the time of the World's Fair in London, there began in England a so-called "lock controversy," which at the time and for some years afterward attracted great interest and attention and occupies a prominent place in the various histories of the lock industry. (See BIBLIOGRAPHY.) A firm of British locksmiths, the Messrs. Bramah, making locks of recognized security, offered a reward to any expert locksmith who could succeed in picking one of their best bank locks. An American named A. C. Hobbs was successful in picking this lock in the presence of an authorized committee, and made for himself a reputation which resulted in his name and genius being availed of by a British firm of manufacturers under the style of Hobbs, Hart & Co., who put the Hobbs lock on the market and have since continued the manufacture of a standard lever-tumbler type of locks of excellent workmanship. As an additional element in this lock controversy, Linus Yale, Jr., discovered how to pick the then celebrated Day and Newell Parautoptic Bank Lock, which was of American origin, but was then known in England as the Hobbs lock. Yale also discovered that he could pick the best bank lock, the "double treasury," which he had himself designed, and finally demonstrated that any lock having a keyhole could be opened by an expert with the necessary skill and time at his disposal. Accordingly Mr. Yale proceeded to develop the combination or dial lock, which in crude forms, as we have already seen, was known for centuries, so that before he died it had displaced nearly all other locks for the protection of bank vaults. The keyhole was done away with, and the external dial took its place. The general use of this lock led to a similar controversy in the United States about 1870, and the Yale bank lock was picked by James Sargent of the firm of Sargent and Greenleaf, of Rochester, New York, a lock inventor and a leading maker of bank locks; but the Sargent lock in turn was picked by an expert of the Yale and Towne Manufacturing Company. This led to improvements which overcame the defects in both locks, and principles were devised and adopted for combination locks such that to-day these locks, even in their cheaper forms, are considered absolutely unpickable by any known process.

Lock Industry. The early lock industry in America followed mainly European and especially British models. The chief point of difference established was the extensive use of cast iron for locks and lock cases, as against wrought iron in Europe. In the first half of the nineteenth century cast iron became highly developed in the United States and found many applications, so that it was but natural that it should enter into hardware and particularly into locks. With improved processes for working sheet metal, especially steel, there was developed in the United States, towards the end of the nineteenth century, a type of lock made of cold rolled and pressed steel, which, made by automatic machinery where the individual parts were punched, stamped, or drop-forged, and developed to a high point of workmanship, soon acquired reputation and a field of usefulness. Constructed by modern processes, where hand labor was superseded by dies and drop forgings, these locks could be made so as to be generally available on the score of expense. Constant improvements in locks as well as in methods of manufacture have been a feature of the industry rather than the evolution of new principles. In the United States the lock industry is centred chiefly in Connecticut, but there are also manufacturers in eastern Pennsylvania and Illinois.

Bibliography. For the development of early locks, consult John Chubb, "On the Construction of Locks and Keys," in *Proceedings of the Institution of Civil Engineers* (London, 1850); also a paper by Harry W. Chubb, entitled "Locks and Safes," in the *Journal of the Society of Arts* (ib., 1893). Consult also: Charles Tomlinson, *Rudimentary Treatise on the Construction of Locks* (ib., 1853); Geo. Price, *Treatise on Locks* (ib., 1856, out of print); chapter on "Locks," in Clarence Blackall, *Builders' Hardware* (New York, 1899); chapter on "Locks," in Kidder, *Building Construction and Superintendence* (3d ed., New York, 1913); H. R. Towne, *Locks and Builders' Hardware* (New York, 1904); and catalogues of leading manufacturers which contain much descriptive material. See SAFES AND SAFE DEPOSIT VAULTS.

LOCK, IN ENGINEERING. See CANAL; DAMS AND RESERVOIRS; FOUNDATION.

LOCK, or **LOCKE,** MATTHEW (c.1630–77). An English composer. He was born in Exeter and received instruction in the rudiments of music from Wake, organist of Exeter Cathedral. When Charles II made his entry into London after the Restoration, Lock was employed to write the music for the occasion and was afterward appointed composer to the King. He was the first musician of England to compose for the stage and wrote some rather famous instrumental music for *The Tempest* and *Macbeth,* as well as excellent sacred music.

LOCK, WALTER (1846–). An English theologian. He was educated at Marlborough and at Corpus Christi, Oxford, became a fellow of Magdalen College in 1869 and tutor (1870), subwarden (1880), and warden (1897) of Keble College. His connection with this college led to his publishing a biography of John Keble (1892) and annotated editions of *The Christian Year* (1895) and *Lyra Innocentium* (1899). He was general editor of the Westminster commentaries on the Revised Version and of the Oxford commentaries, and author of *St. Paul the Master Builder* (1899) and *The Bible and Christian Life* (1905).

LOCKE, DAVID ROSS (1833–88). An American humorist, born in New York, known by his assumed name of Petroleum V. Nasby. Locke first attracted attention by letters published in the Findlay *Jeffersonian* in 1860 with the signature Rev. Petroleum Vesuvius Nasby. They purported to emanate from a poor and ignorant Democrat with a yearning for the postmastership and whisky and an admiration for the institution of slavery. The character was dramatically developed in a series of amusing incidents. The letters were soon transferred to the Toledo *Blade,* of which Locke became editor and in part proprietor. They were of great assistance to the war administration of Lincoln by meeting the criticism of the Peace Democrats of the North. Later, their sting was directed against President Johnson and his "swinging 'round the circle." Locke became a popular lecturer and in 1871 moved to New York and finally returned to Toledo. He published in book form: *Divers Views, Opinions, and Prophecies of Yours Truly* (1865); *Swingin' 'round the Cirkle* (1866); *Ekkoes from Kentucky* (1867); *The Struggles—Social, Financial, and Political—of P. V. Nasby* (1872), in which the best of his humorous work was gathered; *A Paper City* (1878), a novel; *Nasby in Exile* (1882).

LOCKE, JOHN (1632–1704). An English philosopher, born at Wrington, near Bristol, on Aug. 29, 1632. His father was an attorney and also served as captain in the Parliamentary army during the Civil War. Locke was sent for his education to Westminster School, where he continued till 1652, when he became a student of Christ Church, Oxford. After his graduation he took pupils, and from 1661 to 1664 he lectured in Oxford on Greek, rhetoric, and moral philosophy. In 1665 he went to Cleves as secretary to the British Envoy, but soon returned to his studies at Oxford, where he devoted himself to medicine for a while. In 1666 he made the acquaintance of Lord Ashley, afterward Earl of Shaftesbury, and on his invitation went to live at his London house and became his family physician. It was in Lord Ashley's house that he had his attention directed to the importance of undertaking an investigation of the limits of human understanding. This investigation resulted many years after in the publication of his famous *Essay.* In 1672, when Shaftesbury became Lord Chancellor, Locke was appointed Secretary of Presentations, a post which he afterward exchanged for that of Secretary to the Council of Trade. He was employed to draw up a constitution for the American Province of Carolina, but the constitution was never adopted. After Shaftesbury's fall in 1675 Locke took up his residence at Montpellier for the benefit of his health. Here he formed the acquaintance of the Earl of Pembroke, to whom his *Essay* is dedicated. In 1679 he rejoined the Earl of Shaftesbury in England; but in 1682 the Earl fled to Holland, to avoid a prosecution for high treason. Although there is no evidence to warrant the belief that Locke was implicated in any treasonable practice, he was under surveillance and in the following year followed the Earl to Holland and so far shared with him the hostility of the government of Charles as to have his name erased, by royal mandate, from the list of students of Christ Church. Even in Holland he was demanded of the States-General by the English Envoy; but he contrived to conceal himself under the assumed name of Dr. Van der Linden, till the English court ceased to trouble itself on his account. In 1687 his *Essay Concerning Humane Understanding,* begun 17 years before, was finished; and an abridgment of it was published in French (1688) by his friend Le Clerc, in his *Bibliothèque Universelle,* in which Locke had published two years before his *New Method of Making Commonplace Books.* In 1689 he came back to England in the fleet that conveyed the Princess of Orange. He soon obtained from the new government the situation of Commissioner of Appeals, worth £200 a year. He took a lively interest in the cause of toleration and in maintaining the principles of the Revolution. In 1689 there appeared anonymously his first letter on "Toleration," the second letter in 1690, the third in 1692, and the fourth in 1706 (after his death). In 1690 his *Essay Concerning Humane Understanding* was published and met with a rapid and extensive celebrity, although Locke himself received only £30 for the copyright of the first edition. In the same year there appeared his well-known *Treatises on Government*. In 1691 he was engaged upon the momentous question of the restoration of the coinage and published a tract on the subject, followed by other financial papers in 1695. In 1693 was published *Some Thoughts of Education*. In 1696 King William appointed him member of a new council of trade at a salary of £1000. *The Reasonableness of Christianity*, anonymously published in 1695, had been written to promote William's favorite scheme of a comprehension of all the Christian sects in one national Church. In this work he argued the necessity of identifying Christianity, not with a belief in mysteries such as the incarnation and the atonement, but with the gospel of love. He maintained a controversy in defense of this book; he had another controversy in defense of the *Essay*, against Stillingfleet, Bishop of Worcester. His feeble health compelled him to resign his office in June, 1700, and he spent the remainder of his life at Oates in Essex, at the seat of Sir Francis Masham, who had taken Locke into his home in 1691. His last years were very much occupied with the study of the Scriptures, on which he wrote several dissertations, which, with his little work entitled *On the Conduct of the Understanding*, were published after his death. He died Oct. 28, 1704, leaving quite a number of unpublished writings.

Great as were Locke's services to his country and to the cause of civil and religious liberty, his fame rests on the *Essay Concerning Humane Understanding*, which marks an epoch in the history of philosophy. His purpose was to inquire into the powers of the human understanding, with a view to finding out what things it was fitted to grapple with, and where it must fail, so as to make the mind of man "more cautious in meddling with things exceeding its comprehension, and disposed to stop when it is at the utmost extent of its tether." He institutes a preliminary inquiry in the first book as to the existence of innate ideas, theoretical and practical, on which the philosophical world has been much divided. (See COMMON SENSE, PHILOSOPHY OF.) Locke urges against the existence of these supposed innate conceptions or intuitions of the mind the fact that there is no truth universally accepted by mankind. Having thus repudiated the intuitive sources of our knowledge or ideas, he is bound to show how we come by them in the course of our experience. Our experience being twofold, external and internal, we have two classes of ideas—those of sensation and those of reflection. He has therefore to trace the recognized conceptions of the mind to one or other of these sources. Many of our notions are obviously derived from experience, as colors, sounds, etc.; but some have been disputed, more especially ideas of space, time, infinity, power, substance, cause, moral good and evil; and Locke discusses these at length, by way of tracing them to the same origin. This is the subject of book ii, entitled "Of Ideas." Book iii is on language considered as an instrument of truth and contains much valuable material. Book iv is on the nature, limits, and reality of our knowledge, including the nature of demonstrative truth, the existence of God, the provinces of faith and reason, and the nature of error. This work was epoch-making in the history of British philosophy, giving rise to English Empiricism (q.v.), and calling forth as reply Leibnitz's *Nouveaux essais sur l'entendement humain*, in which he canvasses Locke's work chapter by chapter.

In his views on government Locke was a disciple of Hobbes, but he was not slavish in his discipleship. He believed with Hobbes that government is the result of an original contract, but the state of nature preceding the establishment of government he did not believe to be a state of war. Right existed before the foundation of society. Society is a means to the better enjoyment of natural rights. Locke distinguishes in government the three functions of legislation, execution, and adjudication. Of these the legislative function is supreme, but even over this stands the sovereign will of the people. When the people enforce their will against the government, there is no rebellion. They are acting within their rights. In ethics he was a hedonist. Good and bad are equivalent to pleasure and pain or their causes. Moral good is accordance with the law imposed by an authority which rewards us with pleasure for obedience and punishes us with pain for disobedience. The law-imposing authority may be divine or human.

Bibliography. Locke's collected works have been published from 1714 on. A convenient edition of his philosophical works is St. John's (London, 1854), followed by many subsequent issues. The best edition of the *Essay* is A. C. Fraser's (2 vols., Oxford, 1894), with notes; Miss Calkins published a volume of *Selections from the Essay* (Chicago, 1905). For biography, see King, *The Life of John Locke* (London, 1829); Forster, *Original Letters of Locke* (ib., 1830); H. R. Fox-Bourne, *The Life of John Locke* (2 vols., ib., 1876); T. Fowler, *John Locke* (ib., 1880); A. C. Fraser, *Locke* (Edinburgh, 1890)—the last two works give also popular accounts of his philosophy; Charles Bastide, *John Locke: Ses théories politiques et leur influence en Angleterre* (Paris, 1907); H. Ollicon, *La philosophie générale de John Locke* (ib., 1909); Ernst Crous, *Die religionsphilosophische Lehren Lockes und ihre Stellung zu dem Deismus seiner Zeit* (Halle, 1909); and standard histories of modern philosophy. For a fuller bibliography, see Ueberweg-Heinze, *Grundriss der Geschichte der Philosophie* (8th ed., Berlin, 1896). A convenient compendium of Locke's philosophical views may be found in G. E. Russell, *The Philosophy of Locke* (New York, 1891).

LOCKE, JOHN (1792–1852). An American physicist and inventor, born at Freiburg, Me. He was educated at Bethel Academy and at Yale, graduating in 1819, and then entered the navy as a surgeon. Later he settled in the Middle West and became well known as a geologist, botanist, and inventor of scientific instruments. For many years after 1836 he was professor of chemistry in the Medical College of Ohio. He published, among other papers, *Observations on the Terrestrial Magnetism of Several Parts of the United States* (1846).

LOCKE, M. See LOCK, M.

LOCKE, WILLIAM JOHN (1863–). An English novelist, born in Barbados and educated at the Queen's Royal College, Trinidad, and at

St. John's, Cambridge, where he graduated in 1884. By profession an architect, he was secretary from 1897 to 1907 of the Royal Institute of British Architects. He devoted himself also to novel writing, but made no great mark with either critics or the larger public until his *The Morals of Marcus Ordeyne* appeared, in 1905, to be followed by his best book, *The Belovéd Vagabond*, a year later. The first-named story was dramatized and presented (1906) as a play with great success in England and in America. *The Belovéd Vagabond* was also successfully presented (1908) as a play. These two novels are fairly representative of Locke. In them one meets the whimsical, quixotic, eccentric, irresponsible Bohemians for whom he manifests a special affection; and they are characterized by the tolerant humor, the irony, the tenderness, and the chivalrous spirit that belong to this author's personality. The Bohemianism of his novels would perhaps have been something other than it is, had not Murger preceded him with the *Vie de Bohème*, and what his work would have been without the influence of Anatole France, which has left its marks everywhere in it, it is difficult to imagine. To be sure, France's deadly home thrusts and the reckless and fearsome audacities of his irony are not attained, nor indeed attempted, by Locke's amiable, and perhaps a trifle sentimental, talent. Among this author's novels, in addition to the two named above, are: *At the Gate of Samaria* (1895); *Derelicts* (1897); *Idols* (1898); *Where Love Is* (1903); *Septimus* (1909); *Simon the Jester* (1910); *The Glory of Clementina Wing* (1911); *The Joyous Adventures of Aristide Pujol* (1912); *Stella Maris* (1913); *The Fortunate Youth* (1914). Locke's plays, besides those already mentioned, include: *The Palace of Puck* (1907); *Butterflies* (1908); *The Man from the Sea* (1910); *An Adventure of Aristide Pujol* (1912); *Jaffery* (1915).

LOCK'ER-LAMP'SON, FREDERICK (1821–95). An English writer, born May 29, 1821, in Greenwich Hospital, of which institution his father was civil commissioner. For many years he was a précis writer in the Admiralty, Whitehall, but after middle life he devoted himself to travel, society, and literature, and became well known in 1857 by a collection of graceful society verse, entitled *London Lyrics*. He subsequently published an anthology, *Lyra Elegantiarum* (1867; new ed., 1891), and a volume of miscellanies, *Patchwork* (1879), which, made up as it was of selections from various writers, in his opinion brought together "some of the best specimens of *vers de société* and *vers d'occasion* in the English language." Locker married in 1850 Lady Charlotte Bruce, a daughter to Lord Elgin, and after her death the only daughter of Sir Curtis Lampson (1874), from whom he took the name Lampson. He died at Rowfant, May 30, 1895. Ill health precluded his taking any vigorous share in stirring events. He is, however, unexcelled in English as a writer of light verse that is always neat and witty, and never descends to farce or cynicism. Remarkably gifted socially, his wide circle of friends included many of the most distinguished of English men of affairs and men of letters. As a connoisseur, he made collections in various fields, but most important was his large and valuable library, catalogued in the bibliographically useful *Rowfant Library* (1886; with appendix, 1900). His posthumous memoirs, *My Confidences* (1896; ed. by his son-in-law, Augustine Birrell), acquaints the reader with an attractive personality and gives none too high an estimate of his poetry.

LOCKHART, lŏk'härt. A town and the county seat of Caldwell Co., Tex., 30 miles (direct) south of Austin, on the San Antonio and Aransas Pass, and the Missouri, Kansas, and Texas railroads (Map: Texas, D 5). It ships large quantities of planting cottonseed and controls also the trade of a cotton, grain, and livestock region, and has cotton gins and a compress, a cottonseed-oil mill, lumber yards, wagon works, a soap factory, etc. Pop., 1900, 2306; 1910, 2945.

LOCKHART, GEORGE (1673–1731). A Scottish Jacobite. He was a member of Parliament from 1702 to 1715, and in 1706 he was one of the commissioners for the union with England. For plotting with the Jacobites he was twice imprisoned in Edinburgh Castle; and after his second release he was confidential agent of James Stuart from 1718 to 1727, when the discovery of correspondence forced him to go into hiding and subsequently to flee the country. The Duke of Argyll obtained permission for his return in 1728, and thereafter he lived in retirement until he was killed in a duel. His *Memoirs Concerning the Affairs of Scotland* (1714; 3d ed., 1714), together with certain correspondence and papers, were published as *The Lockhart Papers* (2 vols., 1817), a valuable source for Jacobite history.

LOCKHART, JOHN GIBSON (1794–1854). The son-in-law and biographer of Walter Scott. He was the son of Rev. John Lockhart and was born in the manse of Cambusnethan, Scotland, July 14, 1794. Two years later his father became minister of the College Kirk in Glasgow. From the high school and the University of Glasgow young Lockhart proceeded to Balliol College, Oxford, where he graduated in 1813. He afterward studied law at Edinburgh and became an advocate at the Scottish bar (1816). Already interested in literature, he made a German tour in 1817, visiting Goethe at Weimar. In April of the same year *Blackwood's Magazine* was founded, and Lockhart soon became one of its chief contributors. In the October number he assailed Coleridge and Leigh Hunt, the leader of "the Cockney school" of poets; and he had a hand in the buffoonery of "The Chaldee Manuscript." In 1822 he edited Motteux's translation of *Don Quixote*, and in 1823 appeared in book form his good translations of Spanish ballads. In 1819 he published *Peter's Letters to his Kinsfolk*, a satirical description of Edinburgh society. In 1818 he had made the acquaintance of Sir Walter Scott, whose daughter Sophia he married in 1820. Four novels now followed: *Valerius* (1821), a Roman tale, placed in the time of Trajan; *Adam Blair* (1822); *Reginald Dalton* (1823); *Matthew Wald* (1824). *Adam Blair* is a powerful story on the theme to be treated later by Hawthorne in *The Scarlet Letter*. In 1825 Lockhart became editor of the *Quarterly Review*, a position he held for a decade, and in 1843 auditor of the Duchy of Lancaster. In the interval he wrote: *Life of Burns* (1828); *History of Napoleon* (1832); and the work by which he is best known, the *Life of Scott* (1836–38). After Boswell's *Johnson*, this is the most admirable biography in the English language. Lockhart's last years were saddened by domestic troubles.

He retired from the *Quarterly* (1853), resigned the auditorship of Lancaster (1854), and died at Abbotsford, Nov. 25, 1854. Consult Leslie Stephen, in *Dictionary of National Biography*, vol. xxxiv (London, 1893); Andrew Lang, *Life and Letters of Lockhart* (2 vols., New York, 1897).

LOCK HAVEN. A city and the county seat of Clinton Co., Pa., 24 miles by rail west-southwest of Williamsport, on the west branch of the Susquehanna River, and on the Pennsylvania and the New York Central and Hudson River railroads (Map: Pennsylvania, F 4). It is the seat of the Central State Normal School and has a public library and a hospital. The city is surrounded by an agricultural and lumbering country, and its industries include several planing mills, a tannery, extensive paper mills and fire-brick works, a large silk mill, and manufactures of furniture, cigars, beer, woven wire, etc. There are municipal water works. Lock Haven was settled in 1769 and was incorporated as a town in 1833, as a borough in 1844, and as a city in 1870. It has adopted the commission form of government. Pop., 1900, 7210; 1910, 7772.

LOCKJAW. An infectious bacterial disease. See TETANUS.

LOCKLAND. A village in Hamilton Co., Ohio, 12 miles north of Cincinnati, on the Cincinnati, Hamilton, and Dayton, the Cincinnati Northern, and the Cleveland, Cincinnati, Chicago, and St. Louis railroads. There are paper mills, a cotton factory, and a roofing plant. Pop., 1900, 2695; 1910, 3439.

LOCKOUT. The withdrawal of employment from a body of men who refuse to accede to the employer's conditions. The lockout is usually distinguished from the strike on the ground that in the lockout it is the employer who directly causes the stoppage of operations, while in the strike the initiative lies with the men. The distinction is wholly superficial, since the workers, by demands that seem to the employer unreasonable, may really be responsible for the lockout, just as the employer, by the imposition of onerous conditions, may force a strike. For this reason most students of the labor problem are convinced that no purpose is served by the distinction which is usually drawn between the two phenomena.

Bibliography. United States Commissioner of Labor, *Twenty-first Annual Report* (Washington, 1900); *Report of the Industrial Commission*, vol. xvii (ib., 1901); C. D. Wright, *Battles for Labor* (Philadelphia, 1906); Harris Weinstock, *Report on the Labor Laws and Labor Conditions of Foreign Countries in Relation to Strikes and Lockouts* (Sacramento, 1910); W. A. Martin, *Treatise on the Law of Labor Unions* (Washington, 1910); Commercial, Labour, and Statistical Department of Great Britain, *Strikes and Lock-outs* (London, 1912); McLaughlin and Hart (eds.), *Cyclopedia of American Government*, vol. ii (New York, 1914). See STRIKES AND LOCKOUTS.

LOCK′PORT. A city in Will Co., Ill., 33 miles by rail southwest of Chicago, situated on the Des Plaines River, on the Sanitary District and the Illinois and Michigan canals, and on the Chicago and Alton and the Atchison, Topeka, and Santa Fe railroads (Map: Illinois, J 2). One of the features of the city is Dellwood Park. There are oil mills, a lock factory, a cereal factory, and stone quarries. The water works are owned by the city. Pop., 1900, 2659; 1910, 2555.

LOCKPORT. A city and the county seat of Niagara Co., N. Y., 26 miles by rail north by east of Buffalo, on the New York Barge Canal and on the New York Central and Hudson River, the International, and the Erie railroads (Map: New York, B 4). The canal, here crossed by the New York Central Railroad bridge, 500 feet in length and 60 feet above the water, passes over the continuation of the Niagara escarpment, 60 feet in height at this point, by means of a tier of two locks, with a combined lift of 49 feet. These are operated by electricity and have replaced an old hand-operated system of five locks. The city has abundant electric power, extensive quarries of limestone and sandstone, a large trade in grain and fruit, and manufactories of milling and woodworking machinery, indurated fibre, pulp and paper, aluminium, glass, flour, brooms, cotton batting, wall board, carriages, rolling-mill products, textiles, crucible steel, etc. The important buildings include the Odd Fellows Home, county jail and almshouse, Federal building, and the courthouse. The government is administered, under a charter revised in 1900, by a mayor, elected every two years, who controls appointments to the boards of health, fire, police, water, assessors, and plumbing, and by a unicameral council, composed of the executive and 10 aldermen, four of the aldermen being elected at large. Administrative officials other than those mentioned are chosen by popular election. The city owns and operates the water works. Pop., 1900, 16,581; 1910, 17,970; 1914 (U. S. est.), 19,581; 1920, 21,308. A settlement sprang up here when the Erie Canal was opened (1825). The village was incorporated in 1829 and the city in 1865. Consult Pool, *Landmarks of Niagara County* (Syracuse, 1897).

LOCKROY, lŏ'krwä' (properly SIMON), EDOUARD ETIENNE ANTOINE (1838–1913). A French journalist and politician. He was the son of the dramatist Joseph Philippe Simon Lockroy (1803–91) and was born in Paris. In 1860 he went to Italy and fought under Garibaldi in the Sicilian campaign. Soon afterward he accompanied Renan as secretary on his travels through Palestine (1860–64). Upon his return to Paris he began his journalistic career and contributed to the *Figaro* and the *Diable à Quatre*. His articles in *Le Rappel* resulted in his being imprisoned for four months (1869). He commanded a battalion during the siege of Paris and was a member of the National Assembly in 1871. During the troubles of the Commune he was arrested and was again imprisoned for a few months. A year later, when editor of *Le Peuple Souvrain*, he was imprisoned for his duel with Paul de Cassagnac, and again for an article in *La Libération du Territoire* (1873). In the same year he was elected to the National Assembly as a member of the Extreme Left. He was Minister of Commerce and Industry (1886–87) and Minister of Public Instruction (1888–89), and he directed the formation of the Universal Exposition of 1889. He was thrice vice president of the Chamber (1889, 1893, and 1903) as head of the Radical party, and Minister of Marine (1895–96, 1898, 1898–99). He was elected to the National Assembly for the last time in 1907. Some of his contributions to the magazines have been gathered into the volumes: *A bas le* *progrès* (1870); *La Commune et l'Assemblée* (1871); *L'Ile révoltée* (1877); *Ahmed le boucher* (1888); *La défense navale* (1899); *Les marines française et allemande* (1904). He also edited the memoirs of his grandmother, Madame Jullien, as the *Journal d'une bourgeoise pendant la Révolution, 1791–93* (1881).

LOCKROY, Joseph Philippe Simon (1803–91). A French dramatic author, born at Turin. He received an excellent literary education, went on the stage as a youth, and was a successful actor. His first attempts in playwriting were in collaboration with Scribe, in *La marraine* (1827) and *Catherine II* (1831); his next with A. Bourgeois and Arnould, in *L'Impératrice et la juive* (1834), *La vieillesse d'un grand roi* (1837), and *La jeunesse dorée* (1849). He was credited with a considerable share in Dumas's drama *La conscience* (1855), and was joint author of *La fée Carabosse* (Lyric Theatre, 1859) and the comic operas *Ondine* (Lyric, 1863) and *Suzanne* (Opéra Comique, 1879). Many of his own pieces were performed at the Opéra Comique, such as *Le bon garçon* (1837), and at the Lyric, *Les dragons de Villars* (1856) and *La reine Topaze* (1856). He also composed genre scenes and vaudevilles.

LOCKS'LEY HALL. A poem by Tennyson (1842).

LOCK'UP'. A place of temporary detention for persons held on a criminal charge pending arraignment or trial and conviction, and for persons detained as witnesses in criminal cases. The term is English, but it is in use in some parts of the United States as the equivalent of jail or police cell. It is not generally applied to prisons or penitentiaries to which criminals are committed after conviction. See Prison.

LOCK'WOOD, Belva Ann (Bennett) (1830–1917). An American lawyer and reformer. She was born at Royalton, N. Y., graduated in 1857 at Genesee College, Lima, N. Y., and after teaching school for 11 years studied law and was admitted to the bar of the District of Columbia in 1873. In 1879 she was admitted to practice before the Supreme Court, under a law admitting women, which she had been instrumental in getting passed. She lectured frequently and became prominent in peace, woman suffrage, and temperance movements. In 1884 and in 1888 she was nominated for President by the Equal Rights party, and in 1896 represented the United States under a commission from the Secretary of State at the Congress of Charities and Corrections held at Geneva, Switzerland. She was a delegate to the Arbitration Convention, New York (1907) and to the International Peace congresses at London (1908) and at Rome (1911); and in 1913 she became a member of the International Peace Bureau at Brussels. She was married in 1848 to Uriah H. McNall, who died five years later, and in 1868 to Dr. Ezekiel Lockwood.

LOCKWOOD, Henry Hayes (1814–99). An American soldier and authority on military tactics. He was born in Kent Co., Del., graduated at West Point in 1836, served in the Seminole War as a lieutenant in the Second Artillery, and resigned his commission in the next year. In 1841 he was made professor of mathematics at the United States Naval Academy, where from 1851 to 1866 he held the professorship of field artillery and infantry tactics. He entered the Union army in the Civil War as colonel of the First Delaware Infantry, was commissioned a brigadier general of volunteers on Aug. 8, 1861, and served in the defenses of the lower Potomac. He commanded a brigade at Gettysburg and in the winter of 1863–64 was commander of the Middle Department, with headquarters at Baltimore. Later he took part in the Richmond campaign. He was the author of *Manual of Naval Batteries* (1852) and *Exercises in Small Arms and Field Artillery* (1852).

LOCKWOOD, James Booth (1852–84). An American Arctic explorer, born at Annapolis, Md., where his father, Gen. H. H. Lockwood (q.v.), was a professor in the United States Naval Academy. He was educated at Bethlehem, Pa., and at St. John's College, Annapolis, and in October, 1873, received a commission as second lieutenant in the army. For the next seven years he served in the West. In 1881 he accompanied Gen. A. W. Greely (q.v.) on his expedition to Lady Franklin Bay, serving as second in command. On April 3, 1882, he was sent to explore the coasts of northwestern Greenland. Traveling with a dog sledge he was supported as far as Cape May, Greenland, on the Polar Ocean, by seven men dragging three sleds. From that point, with Sergeant Brainard, Eskimo Christiansen, and a dog sledge, Lockwood struck across the frozen ocean for Cape Britannia, the farthest point even seen by his predecessors. Reaching Mary Murray Island, named for his sister, he carefully determined its position—83° 24′ N., 40° 46′ W. He added 125 miles of new coast, named Hazen Coast, and gained for America the record for the farthest north, held for three centuries by England. This northing, the only world's record ever verified by a successor, was within 15 miles of the most northern point of land since discovered. Lockwood's opinion that Greenland continued uninterruptedly to the point he had reached was disputed, but is now definitely confirmed. His journey of 1069 miles in 60 days was made without disaster of any kind. The open condition of the Polar Sea in 1883 prevented his surpassing his northing of 1882. With Brainard in 1883 Lockwood reached the Western Polar Ocean and discovered Greely Fjord. He distinguished himself for his loyalty and courage during the winter of fearful privations at Cape Sabine, where he died April 9, 1884. Consult Lanman, *Farthest North* (New York, 1885), and the official *Reports on the Lady Franklin Bay Expedition* (Washington, 1887).

LOCKWOOD, Wilton (1861–1914). An American portrait and flower painter. He was born at Wilton, Conn., and studied under La Farge in New York and for 10 years in Paris. He met his first decided success abroad in 1904, and an exhibition of his paintings and studies in Boston in 1905 assured his reputation in America. Although his art was strongly influenced by La Farge, it is original and personal to a high degree. His portraits are distinguished by a luminous misty atmosphere, subtly harmonious color, refinement of line, and sympathetic and individual characterization. Among the best known are "John La Farge" (Boston Art Museum); "The Violinist" (Skibo Castle, Scotland), awarded the Temple gold medal at Philadelphia, 1898; "Frank Seabury"; "A. J. Cassatt"; "Mrs. Sweetser"; "Grover Cleveland"; "Jerome Wheelock" (Worcester Museum), and "Justice Holmes" (1912, Massachusetts Bar Association). As a flower painter, he is known chiefly for his peonies. Good examples of his work in this field are in the Metropolitan Museum, New York, the Boston Art Museum, and the Corcoran Gallery, Washington. He received silver medals at Paris (1900), Buffalo (1901), and St. Louis (1904), and became a National Academician in 1912.

LOCKYER, lŏk'yẽr, SIR (JOSEPH) NORMAN (1836–1920). An English astronomer and physicist, born at Rugby. He studied in England and on the Continent. In 1857 he was appointed clerk at the War Office, which position he retained for several years, devoting his leisure to the study of astronomy. In 1870 he was appointed secretary of the Duke of Devonshire's commission on scientific instruction and the advancement of science, and in 1871 assistant commissioner. In 1871 also he was Rede lecturer at Cambridge. He was transferred to the Science and Art Department at South Kensington in 1875. Between 1870 and 1905 he was leader of eight eclipse expeditions of the English government. On the foundation of the Royal College, he was appointed professor of astronomical physics and director of the Solar Physical Observatory at South Kensington. When the Observatory was removed to Cambridge in 1913 he resigned his position as director, and became director of the Hill Observatory at Salcombe Regis, near Sidmouth. Lockyer was knighted in 1897; he received honorary degrees from Cambridge, Oxford, Glasgow, Aberdeen, Edinburgh, and Sheffield; and in 1903–04 he served as president of the British Association for the Advancement of Science. His contributions to the knowledge of the physical condition of the heavenly bodies are valuable. He also carried out spectroscopical researches on the chemistry of the sun, for which he was granted the Rumford medal by the Royal Society in 1874. He discovered, simultaneously with Dr. Janssen, the possibility of successful observations of the solar prominences in broad daylight by means of the spectroscope. His name appears together with that of Dr. Janssen on a medal struck by the French government in 1872 in commemoration of the discovery. He also advanced the theory of the origin of cosmical systems, according to which the various orders of the heavenly bodies are alike composed of meteorites. The assumption that there exists a relation between the number of sun spots and the rainfall on the earth is due to his investigations. Among his publications may be mentioned: *Elementary Lessons in Astronomy* (1868–94); *Questions on Astronomy* (1870); *Contributions to Solar Physics* (1873); *Star-Gazing, Past and Present* (1877); *Studies in Spectrum Analysis* (1878); *Report to the Committee on Solar Physics on the Basic Lines Common to Spots and Prominences* (1880); *The Movements of the Earth* (1887); *The Chemistry of the Sun* (1887); *The Meteoritic Hypothesis* (1890); *The Dawn of Astronomy* (1894); *The Sun's Place in Nature* (1897); *Recent and Coming Eclipses* (1900); *Inorganic Evolution as Studied by Spectrum Analysis* (1900); *The Influence of Brain Power in History* (1903); *Stonehenge and Other British Stone Monuments Astronomically Considered* (1906; 2d ed., 1909); *Education and National Progress: Essays and Addresses, 1870–1905* (1907); *Surveying for Archæologists* (1909); *Tennyson as a Student and Poet of Nature* (1910). He also made numerous contributions to the *Proceedings* of the Royal and the Royal Astronomical societies.

LOCLE, lô'kl', LE. A town of the Canton of Neuchâtel, Switzerland, situated on the French frontier, 5 miles southwest of La Chaux-de-Fonds (Map: Switzerland, A 1). The town is famous for its watchmaking industry, founded at the beginning of the eighteenth century by D. J. Richard. It has been rebuilt since a fire in 1833, and contains among its educational buildings an imposing college, a watchmaking institute, a mechanical school, various secondary and industrial schools, besides industrial, scientific, and art museums, and a library. The streets are lighted by electricity. Pop., 1900, 12,600; 1910, 12,759.

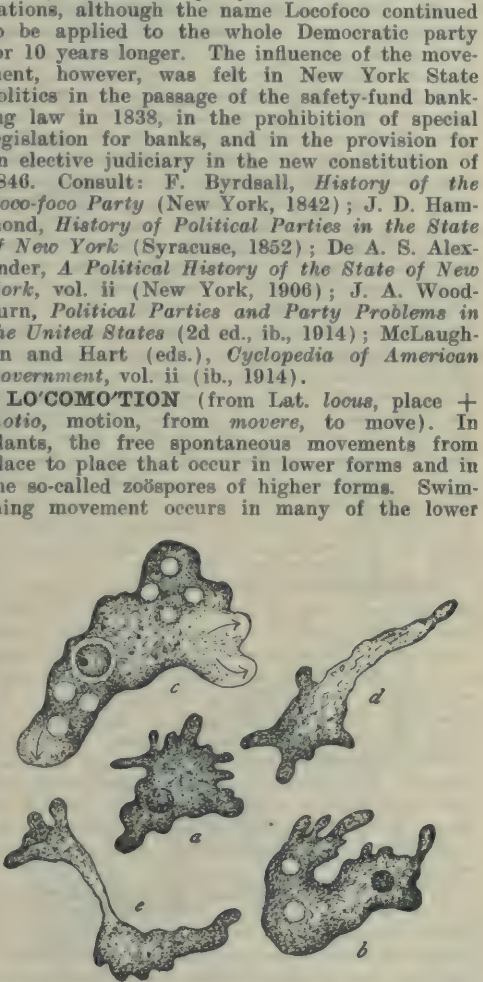
LO'CO (Sp., crazy) **DISEASE.** A disease of sheep, horses, and occasionally cattle, caused by certain species belonging to the botanical order Leguminosæ, popularly known as loco or crazy weeds, and widely distributed over the grazing ranges of the Rocky Mountains, where they occasion extensive losses. The most common species are *Astragalus mollissimus*, or purple loco weed, and *Aragallus lamberti*, or white loco weed. The disease may be called a pernicious habit, which is readily acquired by healthy animals through imitation of locoed animals, consisting in the persistent search for and almost exclusive feeding upon loco weeds. Animals that have once contracted the habit and are confined in fields or pastures free from loco weeds in order to effect a cure soon return to the old habit when turned out to range. They are therefore of no value as range stock. The first effects are stimulant, but continued use produces opposite results. The disease may appear in an acute or a chronic form. In the acute form the animal manifests signs of vertigo, moves about in circles, champs the jaws, and seems to be more or less deaf and blind. Death may occur within three days. In the chronic form the animal may linger for months or even years, losing flesh, exhibiting muscular incoördination and various nervous symptoms, finally becoming unable to walk, and dying of starvation or exhaustion. Locoed sheep sometimes shed the fleece. Locoed horses generally stand by themselves on the range; usually move

LOCO WEED.

about very little during the later stages; sometimes they do not drink oftener than once in two or three weeks; frequently they are unsteady and stiff and unduly frightened by ordinary objects; and when driven may run away at any time without apparent reason. No specific medicinal treatment for loco disease has been discovered; cathartics and tonics should be administered and potassium permanganate may be administered in acute cases to oxidize and destroy the poisonous alkaloid contained in loco weeds. Locoed sheep should be confined in feeding corrals and fattened upon alfalfa and roots for market; locoed horses may develop, under judicious feeding, into valuable work animals. All animals addicted to eating loco weeds should be separated from their companions in order to check the spread of the habit. Consult C. D. Marsh, "The Loco-Weed Disease," in *United States Department of Agriculture, Farmers' Bulletin, No. 380* (Washington, 1909). See ASTRAGALUS.

LO'COFO'CO (from Lat. *locus*, place + *focus*, hearth, fire; formed on the analogy of *locomotive*, ignorantly supposed to mean 'self-moving'). In American political history, the name applied originally to the radical or Equal Rights faction of the Democratic party in New York State, in 1835–37, but afterward used by the Whigs to designate the Democratic party generally throughout the nation. The system of granting bank charters in New York by special legislation for each case had given rise not only to favoritism and partisanship, but to bribery, purchase, and open fraud. The activity in chartering new banks in 1834–35, caused by the certainty that the United States Bank would not be rechartered, increased the scandal, and at last aroused some of the New York City Democrats to action. During the summer of 1835 several meetings were held for the purpose of effecting an organization which, at the approaching election, should support only candidates declaring their opposition to special bank legislation and its attendant evils. A mass meeting of this faction was held at Tammany Hall on Oct. 29, 1835, to act upon the report of a special nominating committee. The regular or Tammany Democrats, entering by the back stairs, attempted to control the meeting, but, finding the opposition too strong, turned out the gas and retired, leaving the reformers in darkness. The victors, however, were well provided with candles, which they lighted with *locofoco*, or friction, matches, and proceeded to act on the nominations. The incident of the lights was seized upon by the Democratic press, which derisively dubbed the antimonopolists Locofocos. In January, 1836, a county convention was held at which the new party took the name of the Equal Rights party, and adopted a statement of rights, in which it declared among other things that no legislature had the right to exempt corporations by special charters from the operation of any law, or to grant them special privileges, and that paper money was a vicious circulating medium and gold and silver the only safe and constitutional currency. In the spring elections of 1836 the party nominated candidates for mayor and aldermen, who polled over 3000 votes. On September 15 following a State convention was held at Utica which nominated candidates for Governor and Lieutenant Governor. In New York City, Congressional, Senatorial, and Assembly nominations were made. The Whigs indorsed four of the nominees and they were elected. In the spring city elections of 1837 the party held the balance of power, the vote cast for their mayoralty candidate throwing the city government into Whig hands. A second State convention held at Utica in September, 1837, framed a new State constitution, one of the features of which was the provision for an elective judiciary. President Van Buren's message to the special session of Congress that met in that same month, by adopting almost the identical grounds on financial matters held by the Equal Rights party, did much to bring the mass of the reformers back into the Democratic ranks, a result which was further hastened by the refusal of some of the Whig-Locofoco fusion candidates to live up to their pledges. The party made no more nominations, although the name Locofoco continued to be applied to the whole Democratic party for 10 years longer. The influence of the movement, however, was felt in New York State politics in the passage of the safety-fund banking law in 1838, in the prohibition of special legislation for banks, and in the provision for an elective judiciary in the new constitution of 1846. Alexander, *A Political History of the State of New York*, vol. ii (New York, 1906); J. A. Woodburn, *Political Parties and Party Problems in the United States* (2d ed., ib., 1914); McLaughlin and Hart (eds.), *Cyclopedia of American Government*, vol. ii (ib., 1914).

LO'COMO'TION (from Lat. *locus*, place + *motio*, motion, from *movere*, to move). In plants, the free spontaneous movements from place to place that occur in lower forms and in the so-called zoöspores of higher forms. Swimming movement occurs in many of the lower algæ and fungi, in zoöspores of higher algæ, and in sperms of mosses and ferns. It is found as far up the scale of plant life as the gymnosperms, the Cycads, and Gingko, in which the male cells are freely motile. A creeping (amœboid) movement over a moist surface occurs in the masses of naked protoplasm (plasmodia)



AN AMŒBA.

Sketched at intervals of half a minute. Cf. particularly *d* and *e*. The smaller end of *e* will probably next move into the larger, thus effecting translation.

which constitute the vegetative stage of slime molds. Swimming movements are usually due to the rapid lashing of long or short protoplasmic processes (cilia) which propel the organism through the water. They are very minute and often numerous, the entire surface of some zoöspores (e.g., those of Vaucheria) being covered with them. Sometimes, however, there are four, three, two, or only one. In such cases they are longer than when more numerous. A single large cilium is often termed a flagellum.

The mechanism of the movement of diatoms is not yet fully known. Some forms creep by means of protrusions of the protoplasm through the slit (raphe) which traverses the siliceous wall lengthwise. Amœboid movements are brought about by a flowing motion of the naked protoplasm which composes the organism. One or more processes form on one side of the body and elongate and the plasma flows slowly away from other regions to enter these processes. If this be continued in one direction the whole protoplasmic mass may creep over the substratum, material being thrust out in front and drawn in from behind. It has been suggested that this form of movement is due to variations in the surface tension of the protoplasmic mass. These variations may be due to unequal oxidation at different points on the surface. But nothing is known with certainty in this regard. It may be that the rotation of the protoplasm within certain walled cells is a form of amœboid movement.

Certain other forms of free movement which are sometimes confused with true locomotion are not the result of inherent energy at all, but are merely the effects of external forces. Such are the migrations of the wind-blown tumbleweeds, and of all winged seeds, pollen grains, etc. Also the movements of certain seeds provided with hygroscopic awns are purely physical. Alternate wetting and drying cause these awns to change their form and position and thus to displace the seeds or to force them into the earth. See MOVEMENT; ROTATION.

LO′COMO′TIVE (from Lat. *locus*, place + ML. *motivus*, moving, from Lat. *movere*, to move, Skt. *mīv*, to push). A steam engine and boiler mounted on wheels and so connected with them as to be capable of self-propulsion along a railway track; specifically, a railway engine. By extension the term has come to be applied to other motors than steam engines, which are similarly mounted and self-propelling, as compressed-air locomotives, electric locomotives, etc. The locomotive as a railway engine operated by steam is alone considered in this article. See COMPRESSED-AIR LOCOMOTIVE; ELECTRIC RAILWAYS.

Early History and Development. The locomotive engine was first developed for use on common roads (see AUTOMOBILE); it was not until 1804 that it was applied to railway operation by Richard Trevithick. Little is definitely known of the Trevithick locomotive first used on the Merthyr-Tydvil Railway beyond the fact that it had a return tubular boiler, a tall smokestack, into which the cylinder steam exhausted, and a cylinder 8 inches in diameter, and 4½-foot stroke. Another point which deserves to be noticed is that Trevithick recognized the sufficiency of the adhesion between a plain cylindrical wheel and a smooth rail for securing the necessary tractive power, but he recognized also that under certain conditions this adhesion would be insufficient and provided for toothed wheels and rails to be used in such cases. Trevithick's locomotive made no more than one or two trips on the Merthyr-Tydvil Railway. Commercially it was regarded as a failure. In hope of something better growing out of it, however, Mr. Blackett of the Wylam Colliery, near Newcastle-on-Tyne, wrote to Trevithick in Cornwall in 1809 with reference to the construction of another engine. Trevithick at first refused to consider the matter, but apparently reconsidered his decision; for in 1811 he sent a locomotive to Newcastle-on-Tyne, which for some reason was laid aside, and finally set to drive an iron foundry. In the same year (1811) Matthew Murray built for John Blenkinsop, the proprietor of the Middleton Colliery, near Leeds, a locomotive in which the steam cylinders operated a toothed wheel which engaged with a toothed rail laid alongside one of the track rails. In Murray's locomotive the boiler was cylindrical and horizontal, with slightly convex ends, and had a single internal flue in which the fire grate was placed at one end and out of which the chimney rose at the other. There were two steam cylinders located on top of the boiler and projecting downward into the boiler. The cylinders were upright and double-acting. Each piston rod was so connected with a pair of cranks, one on each side of the engine, as to drive a toothed wheel, the two wheels thus driven by the two pistons being made to gear with a larger toothed wheel

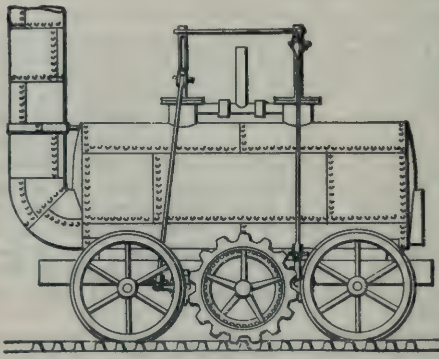


FIG. 1. MURRAY'S LOCOMOTIVE FOR BLENKINSOP'S RAILWAY, 1811.

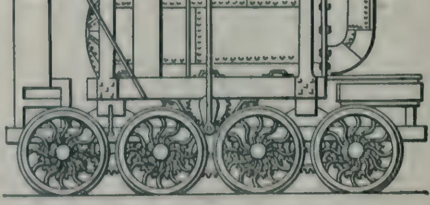

FIG. 2. HEDLEY'S ENGINE, 1815.

which meshed with the toothed rail. The engine was carried on four smooth wheels in the manner of an ordinary road wagon. Murray's engine is stated to have hauled a load of 30 loaded coal wagons weighing 94 tons at a speed of 3½ miles per hour on a level, and to have hauled 15 tons up a grade of 1 foot in 15 feet. While Murray's engine was being operated regularly between Middleton and Leeds, Mr. Blackett of Wylam with his engineer, William Hedley, was at work on a locomotive based on the one purchased from Trevithick as noted above. Mr. Hedley made first a series of experiments to determine the sufficiency for railway operation of the adhesion between smooth wheels and smooth rails. These experiments proving satisfactory, he designed and built his first engine in 1813. It had a cast-iron boiler, with a single internal flue, a cylinder 6 inches in diameter, and a flywheel. The engine worked by the adhesion of its driving wheels upon smooth rails. The boiler was deficient in steaming power and serious inconvenience was felt from the want of a second cylinder. The results were such, however, as to encourage Mr. Blackett to commission Mr. Hedley to make another and better engine. This engine had a wrought-iron boiler with a return flue, the chimney being placed at the same end as the fire box. Two vertical cylinders were employed, one on each side of the engine. The piston rods of these cylinders connected with beams the opposite ends of which were hinged, and the connecting rods were connected to the beams midway between the piston rod connections and the hinges and extended downward to cranks operating toothed wheels which, by means of a chain of gear wheels, operated the two pairs of wheels upon which the engine was carried. In 1815 another locomotive was built by Hedley similar to the one just described, but larger and heavier and having eight wheels instead of four wheels (Fig. 2).

The Hedley engines presented two notable advances over previous locomotives. The first was the use of a return tubular boiler and the second was the adoption of a smokestack of small diameter in which the exhaust cylinder steam could produce an effective draft. Almost before the practicability of Hedley's engines had been proved on the Wylam Railway, George Stephenson had recommended the adoption of locomotives by the managers of the Killingworth Colliery. It was finally decided to construct a locomotive, and the work was done in the colliery machine shops after the designs and under the direction of Stephenson. The engine which was finally turned out of the shops was supported on four wheels, and had a wrought-iron horizontal boiler 8 feet long and 34 inches in diameter, with a single internal flue 20 inches in diameter having a grate in one end and a 20-inch stack leading out of the other end. There were two vertical 8 × 24-inch cylinders, the motion of whose pistons was conveyed to the four driving wheels by an arrangement almost identical with that used by Hedley. The engine was greatly inferior to both Murray's and Hedley's engines previously described. Stephenson's first engine was completed on July 25, 1814, and the following year he completed a second. This engine was notable because of the fact that the pistons were linked directly to cranks on the driving wheels, and the toothed wheels and chain of gearing previously employed were abandoned. Briefly described, this engine had a horizontal cylindrical boiler with a vertical steam cylinder mounted on its top at each end. The piston rod of each cylinder was connected to the centre of a horizontal crosshead extending transversely across the boiler and long enough so that connecting rods attached to its two ends and extending downward to the cranks on the wheels would clear the boiler on each side. The two pairs of driving wheels were connected together by an endless sprocket chain to insure uniformity and coincidence of rotation. In later engines Stephenson substituted rigid side rods for the sprocket chain and supported a portion of the weight of the engine upon pistons contained in vertical cylinders beneath and communicating freely with the interior of the boiler, the pistons being made to press downward upon the bearings of the axles.

The engines built by Stephenson for the Stockton and Darlington Railway were substantially of the construction just described. They were not very satisfactory machines, and Timothy Hackworth, the locomotive engineer of this road, undertook to improve upon them. His engine, the *Royal George,* was completed in 1827. The boiler was a plain cylinder 13 feet long and 4 feet, 4 inches in diameter and had a return flue like the Hedley engines used on the Wylam Railway. There were six coupled wheels 4 feet in diameter, and the cylinders, which were placed at the end opposite the fire door and stack, were so arranged that they overhung the sides of the boiler sufficiently for the downward-projecting piston rods to clear it and to connect through connecting rods with cranks on the rear pair of wheels. These rear drivers were rigid, but the others had springs. The *Royal George* had a cistern into which a portion of the exhaust steam could be turned to heat the feed water; it also had short-stroke force pumps worked by eccentrics, adjustable springs instead of weights upon the safety valves, a single lever reversing gear, and a blast pipe by which the exhaust cylinder steam created a draft in the smokestack.

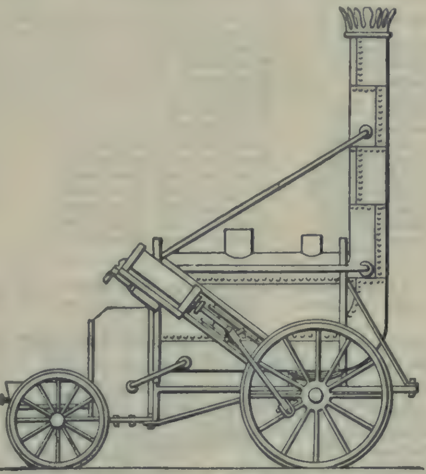

Fig. 3. STEPHENSON'S ROCKET, 1829.

Nothing further of importance respecting the mechanical development remains to be noted until the trials instituted by the Liverpool and Manchester Railway in 1829, which are noted in the article on Railways. Four locomotives were submitted to undergo this trial and three of them were actually tested. The result of the trial was the award of the prize to the *Rocket*, submitted by George Stephenson in the name of his son Robert Stephenson. The *Rocket* (Fig. 3) was a four-wheel engine supported on springs and, with a supply of water in the boiler, weighed 4 tons, 5 hundredweight. The boiler was a horizontal cylindrical vessel 6 feet long and 3 feet, 4 inches in diameter, traversed by 25 copper tubes 3 inches in diameter, through which the gaseous products of combustion were conveyed from a fire box at one end to a tall stack 12 inches in diameter at the other end. The fire grate was 3 feet wide and 2 feet long in the direction of the boiler, and the fire box was 3 feet deep and surrounded by a 3-inch water space which communicated with the boiler proper by means of two external pipes. The cylinders, placed in an inclined position, were fastened to the outside of the boiler near the fire box, the connecting rods working upon crank pins in the driving wheels, which were placed under the front end of the engine. The cylinders were 8 inches in diameter and had a stroke of 16½ inches; the driving wheels were 4 feet, 8½ inches in diameter. The exhaust steam from each cylinder was carried through a pipe and turned upward into the stack. As the result of the success of the *Rocket*, whose speed exceeded all expectations, the managers of the Liverpool and Manchester Railway ordered several locomotives from the Stephensons. These engines were, however, larger and heavier than the *Rocket*, some of them having 10 × 16-inch, and others 11 × 16-inch cylinders, with 5-foot driving wheels and weighing six and one-half and seven tons. The arrangement of the cylinders was substantially the same as on the *Rocket*, but they were less inclined. The tubes in the boiler were increased to from 90 to 92 in number and were reduced in diameter to 2 inches. A smoke box was also added to the boiler.

* Submitted in Liverpool and Manchester trials by T. Hackworth. † Submitted in Liverpool and Manchester trials by John Ericsson. ‡ Built for Liverpool and Manchester Railway by the Stephensons as result of success of *Rocket*.

Before taking up the next series of steps in the mechanical development of the locomotive a moment's attention should be given to the performances of the early engines so far mentioned. These are shown in the accompanying table, taken from Zerah Colburn's *Locomotive Engineering* (London, 1871).

The steep inclination of the cylinders of the Stephenson engines caused the machine to rise and sink on the springs at every double stroke, and at moderately high speeds the unsteadiness thus occasioned was considerable. Timothy Hackworth seems to have been the first to conceive of the plan of avoiding this trouble by placing the cylinders horizontally. On March 3, 1830, he made plans for a horizontal-cylinder engine for the Stockton and Darlington Railway, and laid them before the Stephensons, with orders to build an engine in conformity with them. These plans called for an engine with the following essential characteristics: The boiler was a horizontal cylinder with a single internal flue carrying a grate in one end, and the wheels were four in number, 5 feet in diameter and coupled. A copper steam dome was placed on the boiler, and from this feature the engine received its name of the *Globe*. The forward axle was the driving axle, and it had two cranks between or inside the wheels. The cylinders were horizontal and were located underneath the rear end of the boiler between or inside the rear wheels. Defined briefly as to its cylinders, the *Globe* was a horizontal, inside-cylinder, direct-connected locomotive. The *Globe*, according to Zerah Colburn, was not delivered to the Stockton and Darlington Railway until after the Stephensons, by whom it was being built, had embodied its arrangement of cylinders and driving axle in the *Planet*, the first inside-cylinder engine made by that firm for the Liverpool and Manchester Railway. This engine left Newcastle on Sept. 3, 1830, and was placed in operation on Oct. 4, 1830. Before the *Planet* had left Newcastle, however, Edward Bary, of Liverpool, had placed an inside-cylinder engine designed by Mr. Kennedy, his shop foreman and subsequent partner, on the Liverpool and Manchester Railway. This engine, known as the *Liverpool*, had four wheels of the then great diameter of 6 feet. The cylinders were placed nearly horizontally and side by side; the boiler contained a number of convoluted flues, and the fire was urged by bellows worked from beneath the tender. The *Liverpool* commenced working on July 22, 1830. Of the three locomotives the *Globe*, the *Liverpool*, and the *Planet*, the last was the only one which combined horizontal inside cylinders, a cranked axle, and a multitubular boiler. The *Planet* was the prototype of the modern English locomotive, and in it the locomotive engine assumed a definite and permanent form. It was the standard model of the locomotives built by the Stephensons for many years, and also the model from which both British and American engineers copied freely and minutely. The main dimensions of the *Planet* were as follows: Weight, loaded, 9 tons; weight of tender, 4 tons; cylinders, 11 × 16 inches; diameter of driving wheels, 5 feet; diameter of leading wheels, 3 feet; length of boiler, 6 feet; diameter of boiler, 3 feet; fire-box heating surface, 37¼ square feet; number of tubes, 129; diameter of tubes, 1⅝ inches; tube heating surface, 370 square feet; net load hauled, 76 tons at a maximum speed of 15½ miles per hour. To summarize briefly, the three inventors who stand highest in the long roll of those who have developed the railway locomotive are Richard Trevithick, Timothy Hackworth, and George Stephenson. As a true inventor Trevithick ranks first; as a noted authority well remarks, "it was he who first broke through the trammels of Watt's system of construction and low, if not negative, pressure; it was he who first employed the internal fireplace and internal heating surface; he was the first to create or promote a chimney draft by means of exhaust steam—the first to employ a horizontal cylinder and cranked axle, and to propose two such cylinders with the cranks at right angles to each other, the first to surround the cylinder with hot air, the first to draw a load by the adhesion of a smooth wheel upon a smooth iron bar, and the first to make and work a railway engine." Notwithstanding this note of its merits, Trevithick's genius was of an impracticable kind, and the practical engineering and business ability of Hackworth and Stephenson were necessary to develop the locomotive into a practical commercial machine. Hackworth stamped a character upon the structure of the locomotive engine which it still retains, while it is as the champion in that great contest against the ignorance and prejudice of the public which finally made the steam locomotive the unchallenged means of motive power for railways, that the name of George Stephenson must ever shine above the others.

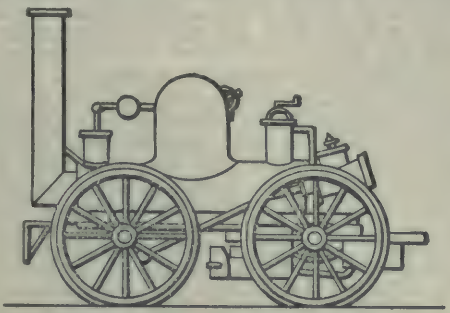

FIG. 4. DE WITT CLINTON, 1831.

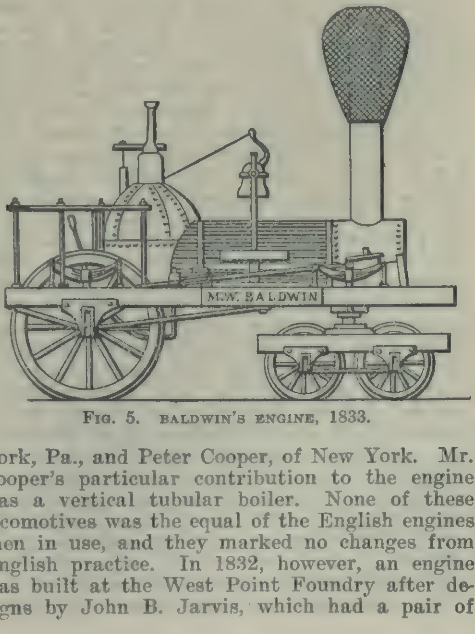

FIG. 5. BALDWIN'S ENGINE, 1833.

The development of the locomotive engine in America dates from 1830, when the *Best Friend*, designed by Adam Hall, and built at the West Point Foundry in New York City, was put at work on the Baltimore and Ohio Railroad. Locomotives had been previously used on American railways, but they were imported from England, while the *Best Friend* was of American construction and design. The *Best Friend* had a vertical tubular boiler, carried at one end of a horizontal platform or frame, while the cylinders were carried at the other end, and the four wheels occupied the space between the boiler and the cylinders. The cylinders were inclined, 8 inches in diameter, and 16-inch stroke, and coupled direct to the rear axle. The two pairs of wheels were coupled together by side rods. This locomotive was destroyed after working about six months by a boiler explosion. In 1831 the West Point Foundry built a second engine, which was put at work on the Mohawk and Hudson Railroad, now a part of the New York Central and Hudson River Railroad. This second engine, known as the *De Witt Clinton*, was very similar in general form to the first, but possessed several improvements. During the same year an engine resembling very closely the Hedley engines previously described was built by Phineas Davis, of York, Pa., and Peter Cooper, of New York. Mr. Cooper's particular contribution to the engine was a vertical tubular boiler. None of these locomotives was the equal of the English engines then in use, and they marked no changes from English practice. In 1832, however, an engine was built at the West Point Foundry after designs by John B. Jarvis, which had a pair of driving wheels and a four-wheeled swiveling truck. Ross Winans had already, in the previous year (1831), introduced the passenger car with swiveling trucks. The engine was designed to burn anthracite coal; the English locomotives all burned bituminous coal. Other engines were built by William T. James, of New York, Col. Stephen H. Long, of Philadelphia, Davis & Gartner, of York, Pa., and Robert L. Stevens, of Hoboken, N. J.

The origin of locomotive building as a commercial industry in America dates from 1832, when William Norris started a shop in Philadelphia, and from 1834, when Mathias Baldwin started a shop in the same city. Baldwin's first engine designed for actual railway operation was a close model of the English engines of the *Planet* class, but his second engine had a pair of driving wheels and a four-wheeled swiveling leading truck. The Norris engines were of the same general form as the second Baldwin locomotive. Some few of the engines turned out by these two builders were outside connected, i.e., the piston rods and connecting rods were outside the driving wheels, but this construction did not become common practice until later. A novel type of engine, known as the "grasshopper" engine, was produced about this time, having a vertical boiler and vertical cylinders, the piston being connected to a beam pivoted at one end and having at the other a connecting rod connecting by crank and gears with the driving wheels. One of these engines weighed 6½ tons and was operated at a speed of 12 to 15 miles an hour, doing the work of 42 horses at a cost of $16 for the round trip, as compared with $33 for horse haulage. In 1834 the Locks and Canals Company, of Lowell, Mass., and in 1840 Hinckley & Drury, of Boston, Mass., began building locomotives. The engines built by the latter firm were all outside-connected machines. The builders and inventors who have been named produced among them all the various features typical of the modern locomotive. It was necessarily given such form that it would work safely and efficiently on rough, ill-ballasted, and often sharply winding tracks; and it soon became evident that the two pairs of coupled driving wheels, the forward swiveling truck, the system of equalizing suspension bars by which the weight is distributed fairly among all the wheels, whatever the position of the engine or whatever the irregularity of the track, were essential features of a locomotive working under such conditions. Time, moreover, has shown that they were also excellent features for smooth roads.

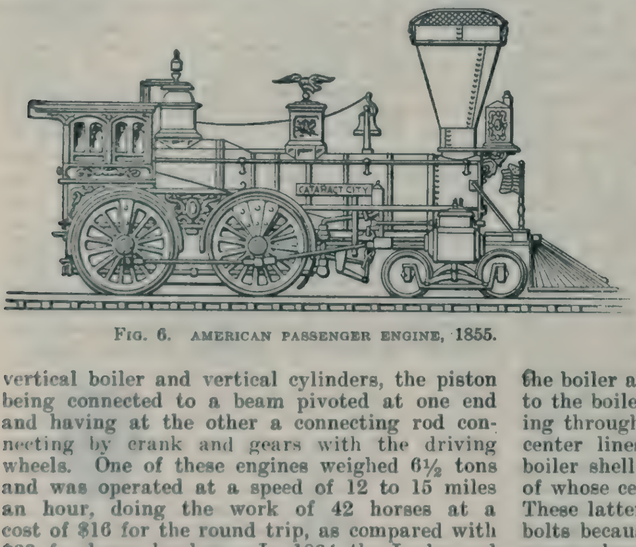

FIG. 6. AMERICAN PASSENGER ENGINE, 1855.

The cowcatcher, or pilot, placed in front to remove obstacles from the track, the bell, and the whistle were also American developments. The severity of the winter storms compelled the adoption of the cab, and the use of wood for fuel led to the invention of the spark arrester for wood-burning engines. Netting is now used in coal-burning locomotives to prevent the throwing of sparks. The sand box from which sand is led through pipes to the rails to prevent slipping of the driving wheels is also largely an American development.

Construction. Structurally a locomotive consists of a frame, the boiler and engine supported by it, and the running gear on which the whole travels along the track.

The boilers used upon locomotives are of a distinct type. They consist of an approximately cylindrical barrel with a furnace at one end and a smoke box at the other. Fig. 7 shows a longitudinal section through a boiler, and its principal attachments. The fire box proper consists of the side sheets, the top or more properly the crown sheet, the back or door sheet, and the back tube sheet, the front tube sheet being at the smoke-box end of the boiler. The fire box is placed inside a larger and similar shell which forms the rear end of the boiler, so that the fire box is entirely surrounded by water, the space between the fire-box side and end sheets and the corresponding sheets of the outer shell being termed the water space. The gases from the fire are carried to the smoke box through tubes, generally about 2 inches or 2¼ inches in diameter and supported in the front and back tube sheets. These tubes are entirely surrounded by water, the level of the water when there is a fire in the fire box being necessarily kept above the highest point of the crown sheet. A water glass and gauge cocks are provided on the back head of the boiler in the cab so that the engineman may determine the height of the water in the boiler at any time. The fire box is connected to the boiler proper by means of stay bolts passing through the water space as indicated by the center lines and also to the roof sheet of the boiler shell by means of longer stay bolts, some of whose centre lines are also indicated in Fig. 7. These latter are known as crown stays or crown bolts because of their being used to support the crown sheet. Crown bolts are generally known in the modern locomotive as radial stays because of their following approximately the lines of radii of the boiler roof sheet. Formerly the general practice was to use a series of transverse girders known as crown bars which were bolted to the crown sheet and supported by sling stays from the roof sheet. Stay bolts are either rigid or flexible. The rigid bolts are threaded and screwed through both sheets, while flexible bolts have a ball joint at the outer end to permit a slight relative movement of the sheets in expansion and contraction. The United States government requires all rigid stay bolts to be drilled at the outer end with a hole $\frac{3}{16}$ inch in diameter and 1¼ inches deep. These holes are called telltale holes, as in case a bolt breaks they will permit water to escape. In the Belpaire-type boiler it is now general practice to use stay bolts similar to the radial stays previously mentioned, but the roof sheet in this type of boiler is almost flat, while the side sheets near the top are almost vertical and are connected by transverse stays which pass above the crown sheet. The back head and front tube sheet are braced to the shell of the boiler by braces as indicated by the sloping centre lines in Fig. 7.

A Wootten fire box is one which is very wide and shallow, having a crown sheet curved at a large radius. It is used in anthracite-coal-burning locomotives, which require a large grate area because of the slow burning rate of this fuel. Oil is used to a considerable extent as a fuel for locomotives in the western United States and Mexico. It is carried in the tender and is fed, generally by means of a steam jet, into a brick-lined fire box. A combustion chamber, or an extension of the fire box into the boiler shell, is sometimes used, particularly in locomotives with long boilers where the tubes might otherwise be too long. Fire boxes in America are made of steel, as are boiler plates, tubes being either steel or iron. In Europe fire boxes and tubes are commonly made of copper. The fire in coal-burning locomotives is carried on grates, and an ash pan is provided beneath them. The grates are commonly of a rocking type, made of cast iron and with air spaces in them, but water grates are also used to some extent in anthracite-coal-burning engines. Water grates are formed by water tubes connecting the front and back water space of the fire box, with some of the tubes replaced by solid rods that may be drawn out when it is desired to dump the fires. The fire box in Fig. 7 is equipped with a brick arch which is supported on water tubes connecting the front and back water space. These tubes aid in the circulation of the water in the boiler; and while the more common practice is to support the brick arch in this way, it is sometimes carried by tee or angle irons. The brick arch is not in universal use, but is very generally employed in modern locomotives, its function being to force the hot gases to take as long a path as possible on their way to the tubes in order to give up a maximum of heat to the fire-box sheets, which are the most effective part of the boiler's heating surface. Passing through the tubes, where a large proportion of the remaining heat is transmitted to the boiler water, the gases enter the smoke box and are deflected downward by a diaphragm plate which may be either close to the front tube sheet at the top and sloping outward as it passes down towards the exhaust nozzle or may be vertical as shown in Fig. 7. The reason that this sheet is vertical in this case is that the locomotive is fitted with a superheater, the functions of which will be explained later. Draft is created by means of the exhaust steam from the locomotive cylinders, which passes through an exhaust pipe and an exhaust nozzle at the top of this pipe and upward through the stack. Various types of smoke box or front-end arrangements are employed, the one in Fig. 7 making use of a draft or petticoat pipe which is adjustable as to height in order that the force of the draft may be regulated to suit conditions, but the more common practice in modern locomotives is to omit this draft pipe entirely and use an inside extension of the stack terminating just above the exhaust nozzle. A netting indicated in Fig. 7 in front of the draft pipe extends across the smoke box, and in this case an adjustable apron is used just ahead of the exhaust nozzle. This apron is used to regulate the force of the draft in the same way as the draft pipe, and the gases pass under it through the netting, which prevents cinders of large size from being carried through the stack to the atmosphere. The diamond stack, which had a netting placed in it and was formerly used with a short smoke box, has given way universally to some form of open stack and extended smoke box similar to that in Fig. 7.

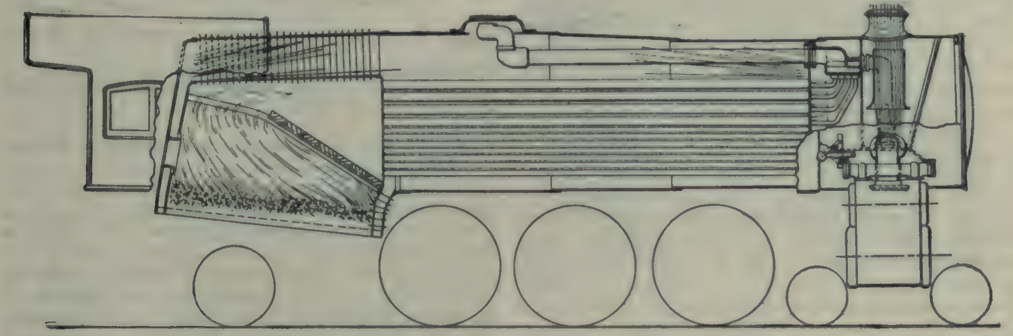

Fig. 7. LONGITUDINAL SECTION THROUGH A LOCOMOTIVE BOILER OF THE EXTENDED WAGON-TOP TYPE.

The types of locomotive boilers in general use are the wagon-top and its successor the extended wagon-top, the straight-top, the conical, and the Belpaire. The wagon-top boiler is cylindrical for some distance back from the smoke box and the diameter is then increased materially by means of one sloping course, the difference between the wagon-top and the extended wagon-top boiler being that in the latter this sloping course is always well ahead of the fire box, while in the former the front-end diameter was carried back almost to the fire box and the slope used to increase the amount of steam space directly over the crown sheet. The straight-top boiler, as its name indicates, is of practically the same diameter throughout its barrel, while the conical tapers gradually from end to end and is merely a modification of the extended wagon-top. The Belpaire type is, as previously stated, a form of construction at the fire-box end and may be used with a barrel of any of the other forms.

In order to obtain the steam for transmission to the cylinders as dry as possible, the throttle valve which controls the admission of steam to the cylinders is placed in a dome connected to the top of the boiler. This valve is controlled, by means of rods and levers, from the locomotive cab by the engineman, the pipe or bonnet which holds the valve being shown in Fig. 7, but not the rods and levers. In the ordinary locomotive, using what is known as saturated steam, the steam passes through the throttle valve to the dry pipe, which is supported in the barrel of the boiler above the tubes, and which passes through a hole in the front tube sheet and is connected by means of a casting known as the nigger head to the branch steam pipes which lead to the steam chests on either side of the locomotive. From the steam chests the steam passes to the cylinders through valves driven from the running gear and is there used to drive the locomotive. The boiler shown in Fig. 7 differs from the ordinary type of boiler in being equipped with a superheater, and as locomotives in large numbers are so equipped, a brief description is given below.

Saturated steam is steam in the form which it takes when it is generated from water by means of heat, and when it comes in contact with a surface cooler than itself a certain amount of it will be turned back into water, resulting in waste. In order to avoid the waste caused by the condensation of saturated steam in the steam chest and cylinders, the plan was hit upon of heating the steam to a still higher temperature after it had left contact with the water so that when this superheated steam comes in contact with a cooler surface it will necessarily give up heat to that surface but will not be immediately turned back into water.

When a boiler is equipped with a superheater a number of large tubes or flues, usually about 5 inches in diameter, replace a portion of the smaller tubes at the top. The steam, after leaving the throttle valve, passes through the dry pipe as before, but the dry pipe is in this case connected in the smoke box to a casing, usually of cast iron, and known as a header. To this header are connected return tubes, known as superheater elements, which pass back into the large boiler flues for some distance and return to a similar header which forms part of the same casting as the header previously referred to. This second header is connected to the branch steam pipes, which in turn connect with the steam chests. Locomotive superheaters vary in form to some extent, but the principle involved in all those in use is practically the same. The steam passes back through the elements referred to, which are absorbing heat from the gases passing through the large flues, and the steam in turn absorbs this heat and becomes superheated before passing through the second header and the steam pipes to the steam chests. The steam pipes were formerly connected to the saddle of the cylinders inside the smoke box, and passages in the casting then led it to the steam chest, but it has not yet been found practicable to use flat or slide valves to control the admission of superheated steam to the cylinders because of a detrimental action which the superheated steam has on this type of valve and its seat. When superheated steam is used, therefore, piston valves, which will be explained later, are invariably used, and it has been found more satisfactory to eliminate the long passages through the cylinder saddle and to carry the steam pipes directly to the steam chests through the sides of the smoke box as indicated in Fig. 7. The counterweight shown on the side of the smoke box in Fig. 7 is part of a damper regulator, this damper shutting off the large flues when the locomotive is drifting with the throttle closed, so that the hot gases will not come in contact with the superheater elements when there is no steam in them and burn them.

Among the necessary fittings of a locomotive boiler besides those already described are safety valve, whistle, steam gauge, water gauge, blower, throttle valve, and injectors.

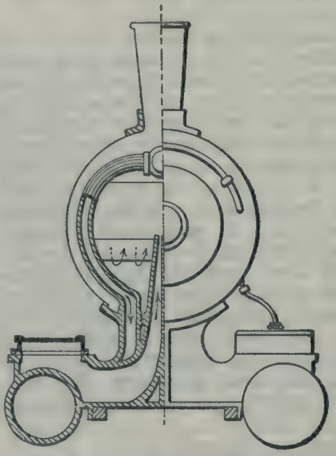

FIG. 8. SECTIONAL ELEVATION OF FRONT END OF A LOCOMOTIVE.

This locomotive differs from that in Fig. 7 in having no superheater and in being equipped with inside steam pipes and slide-valve cylinders.

Safety valves for locomotives are of the pop type, and two or more are employed. Fig. 9 is a section through a safety valve. The valve *a* rests upon the seat *b* and is held in place by the pressure of the spiral spring *d* bearing down on the spindle *c*. The pressure of this spring is regulated by screwing the collar *e* up and down. Outside of the valve seat there is a projection *f* beneath which a groove *g* is cut in the casing. When the valve lifts this groove is filled with steam which presses against the portion of the valve outside of the seat and, by thus increasing the effective area of the valve, causes it to rise higher and remain open longer than it would without this device. The adjustment of the

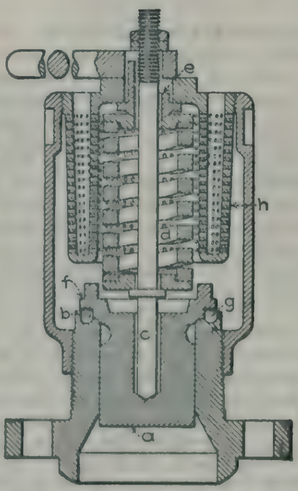

FIG. 9. LOCOMOTIVE SAFETY VALVE.

valve is so made that it will allow steam to escape until the pressure in the boiler is at a desired amount below the normal. The perforated casing or muffler *h* breaks the escaping steam into numerous single jets and thus reduces the noise of the escaping steam.

The *whistle* consists of a bell *A* (Fig. 10) closed at the top and sharpened at the lower edge. By opening the valve shown the steam escapes through the narrow circular orifice *B* and, entering the bell, sets up vibrations which cause the whistle. The tone is controlled by the size of the bell and the pressure of the steam, being lower the larger the bell is, and louder the greater the steam pressure is. Chime whistles are commonly used, and they consist usually of a bell having three compartments, tuned respectively to the first, third, and fifth of the musical scale. Five-chamber chime whistles are also used.

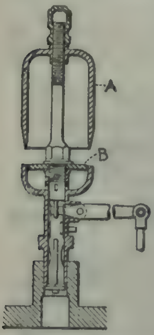

FIG. 10. LOCOMOTIVE WHISTLE.

The *blower* consists of a pipe leading from the cab to the stack, into which it turns upward, so that by opening a valve a jet of steam is sent up through the stack and gives a draft on the fire when the locomotive is standing still and when, consequently, the exhaust is not acting as previously described. The blower and other auxiliaries which require steam from the boiler usually receive it from a fountain or turret which is placed on top of the boiler in the cab and contains a number of valves for connection to the different auxiliaries.

The *throttle valve* in general use is a double-seated poppet valve, shown in section by Fig. 11. As will be seen, there are two valves, *a* and *b*, attached to a single stem. The upper valve, *a*, is the larger, and the lower valve, *b*, is of such diameter that it will pass through the upper valve seat. The steam, therefore, exerts a pressure on the lower face of *b* and on the upper face of *a*, so that the valve is partly balanced, but the valve *a* being larger than the valve *b*, the downward pressure is the greater and tends to keep the valve closed. Considerable force is required to raise the valve against this pressure, and in order that this may be exerted so as to task the strength as little as practicable, the lever arrangement shown is employed. The rod *e* comes from the cab, where it is controlled by the throttle lever in the hands of the engineman, is attached to the bell crank *d*, and this in turn is attached to the valve stem *E*. The point of the bell crank is provided with a slotted hole. At the start of the pull the length of the lever arm is about 2⅓ inches, while the long arm is 9½ inches. These figures vary to suit conditions. After the valve has been lifted from its seat and is free from the excess of pressure on *a*, the projecting horn *A* on the back of the bell crank comes in contact with the bracket *B*, and the crank takes the position shown by the dotted line in the drawing. The end of the horn then becomes the pivot, and the length of the short arm of the lever is changed to 9½ inches and the long arm to about 11½ inches. The dry pipe, as previously explained, is the steam pipe leading from the throttle valve to the engine cylinders, and is shown in Fig. 7. Injectors are used for delivering feed water to the boiler. See INJECTOR.

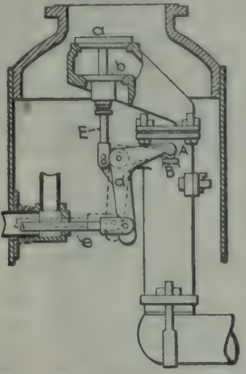

FIG. 11. LOCOMOTIVE THROTTLE VALVE.

The engine, or the mechanism for applying the pressure of the steam generated in the boiler to the rotation of the driving wheels, consists of the cylinders, pistons and piston rods, connecting or main rods, and the parallel or side rods, with their attachments and appurtenances. The cylinders are generally placed one on each side of the locomotive near the front end, as shown in Figs. 7 and 8. Each cylinder, with its valve seat in the case of slide-valve engines and the entire steam chest in piston-valve engines, usually forms one casting with the half saddle. The two half saddles are bolted together and the concave-topped saddle is then bolted to the smoke box of the boiler. The steam chest of a slide-valve engine is made separately and held in place by studs. The saddle affords a support for the boiler, and in turn rests on the frames, as shown in Fig. 8. The steam chest on each cylinder receives the steam from the boiler and contains the valve which admits it to the cylinder. Fig. 12 is a longitudinal section showing the inside of the cylinder and steam chest of a simple locomotive with slide valves. As will be seen, there is a steam port from the chest to each end of the cylinder and between them an exhaust port *b*, the latter connecting with the exhaust pipe and nozzle; the motion of the valve alternately opens and closes the steam ports so as to admit steam first at one end and then at the other end of the cylinder. In the drawing, Fig. 12, steam is shown entering the forward end of the cylinder and exhausting from the rear end. The valve in universal use for many years was a slide valve, roughly of D shape in section as shown in Fig. 12, but piston valves are now generally employed, and universally when superheaters are used. A piston valve is shown in the succeeding section on compound locomotives.

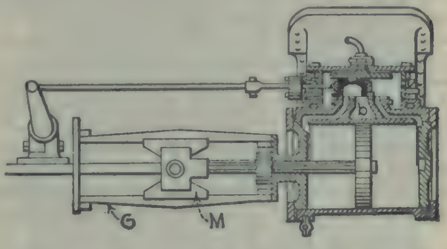

FIG. 12. SECTION THROUGH SLIDE VALVE, CYLINDER, AND STEAM CHEST.

Its principle is the same as that of the slide valve, but it is cylindrical and works in a cylindrical steam chest. The valves are oiled through oil pipes fed from lubricators placed either in the cab or on the running board. The sliding motion of the valve is controlled by a valve stem which connects with a valve rod driven by the valve gear. Various forms of valve gear are employed. The one in most extensive use for many years was the Stephenson link, the operation of which is explained in the article on steam engines. In heavy locomotives, however, the Stephenson gear is difficult to operate because of the weight which has to be lifted, and the parts wear out quickly. This has led to the almost universal use of a valve gear driven from the outside, having connections to the main crank pin and the crosshead.

The valve gear is controlled from the cab by means of a lever known as the reverse lever. Power reverse gear, generally steam, or a hand wheel and screw are much used in modern heavy locomotives in place of a lever. Inside the cylinder works the piston. This is a more or less disk-shaped structure of metal and is made in various ways, but always so as to fit the cylinder steam-tight by means of cast-iron rings sprung into grooves in the piston and bearing against the cylinder walls. The piston must be of ample strength, as it has to convey the pressure of the steam to the piston rod. The piston rod is circular in section and made of forged steel. It passes through the back cylinder head by means of a circular orifice packed so as to be steam-tight and yet allow for the movement of the rod. At its rear end the piston rod connects with the crosshead *M*, working between the guides *G* (Fig. 12). In Fig. 13 are shown another form of crosshead and guides and also the arrangement of the main rod and the side rods for a locomotive with six drivers. Main and side rods are made of forged steel.

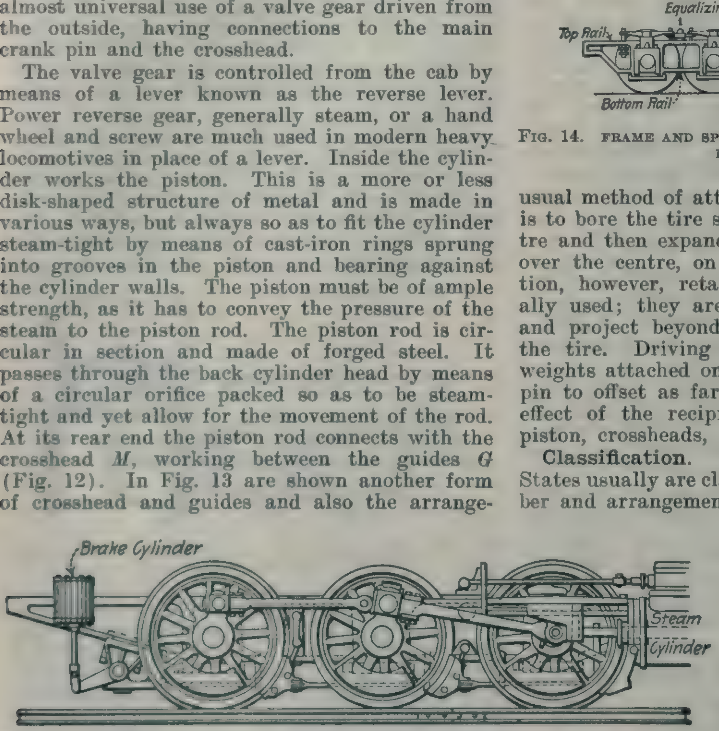

FIG. 13. DRIVING WHEELS, MAIN AND SIDE RODS, CROSSHEAD, GUIDES, PISTON ROD, VALVE ROD, AND BRAKE GEAR OF A LOCOMOTIVE.

The frame of a locomotive supports the boiler and engine on the wheels. In America bar frames are nearly always employed. Fig. 14 shows the frame and spring rigging for a freight locomotive (Consolidation or 2-8-0 type). It will be seen that the top and bottom rails of the frame are connected by vertical struts known as pedestal jaws, between which come the boxes of the driving wheels. These driving boxes have brass bearings which rest on the journals of the axle. On the bottom of the pedestal jaws are bars known as pedestal caps or binders. The number of jaws and style of frame are governed mostly by the number of driving wheels. Locomotives which have trailing wheels under the fire box have an additional frame spliced to the main frame, and the front rails, to which the cylinders are connected, are very often made separate and spliced to the main frame. In order to make an engine ride easily and to reduce the effects of the shock and concussion, the locomotive is provided with springs placed over each driving box and carried on a saddle which straddles the frame and rests on the driving box, as shown by Fig. 14. In order to equalize the weight between drivers there are provided bars between the springs which are called equalizing bars. In underhung spring rigging the springs are under the driving boxes and the weight is transferred to the latter by rods hooked over their tops or by a saddle supported at the bottom of the box.

Driving wheels are made with cast-iron or cast-steel centres, with a forged-steel tire. The usual method of attaching the tire to the centre is to bore the tire slightly smaller than the centre and then expand it by heating until it slips over the centre, on which it shrinks. In addition, however, retaining rings are very generally used; they are bolted to the wheel centre and project beyond the inner circumference of the tire. Driving wheels have counterbalance weights attached on the side opposite the crank pin to offset as far as possible the unbalancing effect of the reciprocating parts, such as the piston, crossheads, etc.

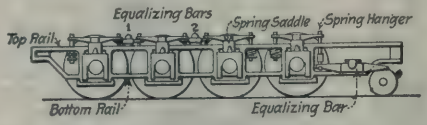

FIG. 14. FRAME AND SPRING RIGGING FOR A CONSOLIDATION LOCOMOTIVE.

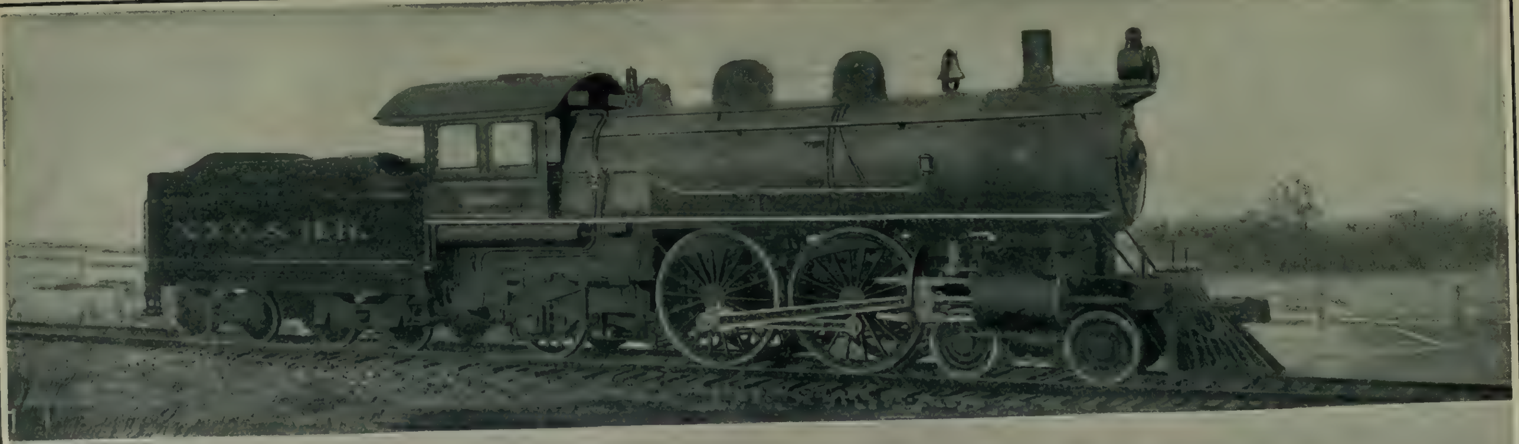
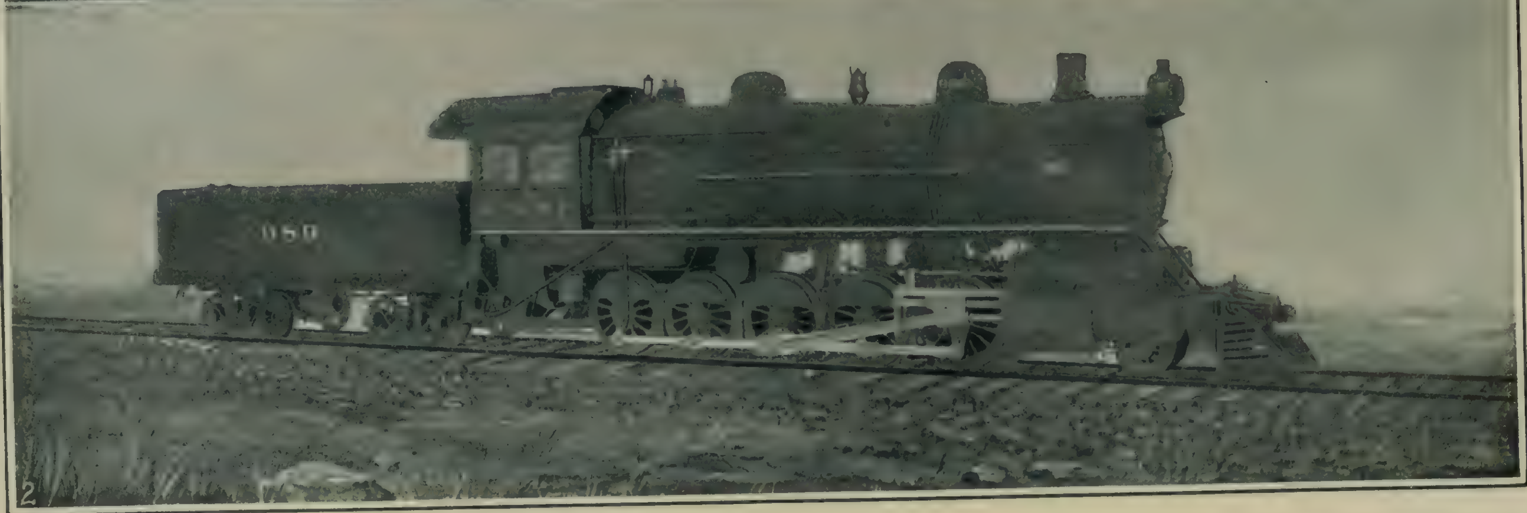
Classification. Locomotives in the United States usually are classified according to the number and arrangement of their driving and truck wheels. A Mogul type locomotive, which has a two-wheel leading truck, three pairs of driving wheels, and no trailing wheels, is designated as a 2–6–0 type; a Pacific type locomotive, with a four-wheel leading truck, three pairs of driving wheels, and two trailing wheels, is designated as a 4–6–2 type; while a Mallet articulated locomotive, with two leading truck wheels, two sets of drivers of three pairs each, and two trailing truck wheels, would be termed as 2–6–6–2 type.

The American or eight-wheel (4–4–0) type locomotive was standard for passenger service in America for many years, while the Mogul (2–6–0) was much used for freight. In passenger service the Atlantic (4–4–2) type succeeded the American to a large extent, the ten-wheel (4–6–0) type also being much used for both passenger and freight service, while heavier freight-train loads brought the Consolidation (2–8–0) type into very general use. The demand for increased boiler capacity led to the general adoption of locomotives in which the boiler was lengthened by adding a pair of trailing wheels to the engine, and this brought into general use the Pacific (4–6–2) type for passenger service and the Mikado (2–8–2) type for freight service.

Some of the more common types are: 0–6–0, 0–8–0, and 0–10–0 switching locomotives; Mogul

LOCOMOTIVES





1. CENTRAL ATLANTIC TYPE PASSENGER LOCOMOTIVE. This type of engine hauled the Empire State Express between Syracuse and Rochester in 1903.
2. DECAPOD TYPE HEAVY FREIGHT LOCOMOTIVE. Designed for Mountain Service.

Built by American Locomotive Company.

(2–6–0); Consolidation (2–8–0); Mikado (2–8–2); twelve-wheel (4–8–0); Santa Fe (2–10–2); American (4–4–0); Atlantic (4–4–2); ten-wheel (4–6–0); Pacific (4–6–2); Mountain (4–8–2); and Mallet compound locomotives of various wheel arrangements such as 0–6–6–0, 0–8–8–0, 2–6–6–2, 2–8–8–2, 2–6–6–0. There is in service one locomotive which has a wheel arrangement designated as 2–8–8–8–2. This machine has an additional set of engines and driving wheels under the tender.

Compound Locomotives. The compound locomotive is one in which the steam is admitted to one cylinder called the high-pressure cylinder, where it partially expands in doing its work, and whence it exhausts either into a receiver pipe or directly into the steam chest of a larger cylinder, called the low-pressure cylinder, where it completes its expansion and finishes its work, being then exhausted to the atmosphere in the ordinary way. The compound principle has been applied to locomotives in several ways: (1) two-cylinder compounds, with a cylinder on each side; the steam passes from the high-pressure cylinder on one side through the smoke box and across the engine to the low-pressure cylinder on the opposite side; (2) three-cylinder compounds, with a high-pressure cylinder on each side, the steam from which exhausts into a low-pressure cylinder beneath the smoke box (this type is not used in America); (3) four-cylinder compounds, with a high-pressure and a low-pressure cylinder on each side of the engine, each pair working independently of the other; (4) four-cylinder balanced compounds (so called because the four cranks, set 90 degrees apart, nearly balance one another), with two inside high-pressure and two outside low-pressure cylinders; (5) Mallet articulated compounds, which have two high-pressure cylinders driving one set of driving wheels and two low-pressure cylinders driving another set.

Recent Developments. Between 1890 and 1920 the American locomotive experienced a wonderful development. In 1890 in America an eight-wheel (4–4–0 type) locomotive with 18 × 24-inch cylinders and a boiler having about 2200 square feet of heating surface was in quite general use for first-class passenger service; the weight on the drivers seldom exceeded 65,000 pounds, and the total weight of the engine was usually within 100,000 pounds in working order. In freight service engines weighing between 100,000 and 120,000 pounds on the drivers were considered powerful locomotives. The standardized Pacific-type locomotive for passenger service built for the United States Railway administration had 79-inch-diameter driving wheels, 27 × 28-inch cylinders, 200 pounds boiler pressure, 3824 square feet of heating surface, 70.8 square feet of grate area, 43,800 pounds tractive effort, a total weight (excluding the tender) in working order of 306,000 pounds, and a weight on drivers of 197,000 pounds.

By 1922 it was evident that even the Pacific type of locomotive was not capable of making the requisite time with the express trains and the Mountain type was taking its place.

The greater part of the freight traffic in the United States is now handled by locomotives either of the Consolidation or Mikado type with four pairs of coupled drivers, while more powerful machines are those of the Santa Fe or the Mallet type, the latter of which is discussed in the next column. Data for two representative Santa Fe locomotives are included in the accompanying table.

The Mallet articulated compound locomotive first came into use in America in 1904, when one of this type (0–6–6–0) was built by the American Locomotive Company for the Baltimore and Ohio Railroad. Powerful locomotives of this type are used on the leading American railways where traffic and grades are heavy, as on the Virginia Railway. Dimensions of typical engines, as of the 2–8–8–2 type, are given in one of the accompanying tables, and it is of special interest to note that, although a low-speed machine, it has developed in service about 3000 horse power.

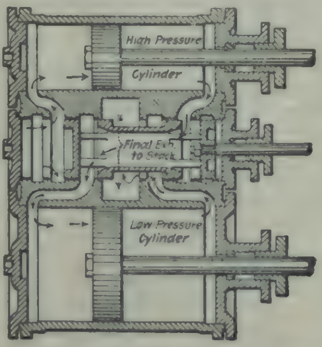


FIG. 15. CROSS SECTION OF CYLINDERS.

The Mallet articulated type takes its name from M. Mallet, the inventor, and the fact that it has an articulation or joint in the frame, the front of the boiler having a sliding bearing on the front running gear, so that in spite of its long wheel base the locomotive can negotiate sharp curves. Locomotives of this type have also been built with a flexible connection in the boiler corresponding to that in the frames, but only in limited numbers. Simple engines of this type have been built, but also in limited numbers. This principle, in 1914, was carried one step farther in a locomotive of the 2–8–8–8–2 type built by the Baldwin Locomotive Works for the Erie Railroad, in which the weight of the tender is used for adhesion by placing under it a set of cylinders and running gear. This locomotive has hauled a test train of 251 loaded cars, but is intended for and is employed in pusher service. The leading dimensions are given in one of the accompanying tables.

The Pacific (4–6–2) type was in most general use in passenger service and the Mikado (2–8–2) and the Consolidation (2–8–0) types in freight service, but as noted both heavier passenger and freight trains are requiring more powerful locomotives. The Santa Fe type is employed where a tractive effort of from 65,000 to 83,000 pounds is required. The use of superheaters and brick arches is now general and has done much towards economy in water and coal and increase in capacity. The mechanical stoker is in successful use on large numbers of locomotives of the larger types, where it also is an important factor in increasing capacity. Superheating by 1922 had been universally adopted in the construction of locomotives for passenger and freight trains. With the introduction of superheating the use of two-cylinder single expansion locomotives had increased, while for powerful engines the preference of the railways was divided between two-cylinder single expansion with superheater, the four-cylinder compound with superheater and the three or four-cylinder expansion with superheater.

This was the general opinion at the International Railway Congress in 1922. Here it was stated according to the summary in the Railway Age that:

"The fuel economy obtained by the application of superheat to the single expansion engines may be estimated on the average, in ordinary working conditions, to be about 10 to 20 per cent. This economy, however, is quite variable, according to the work done and the condition in which the parts are kept, and it is necessary to be more particular in this upkeep than with saturated steam engines. The special arrangements of valves and pistons of superheated engines have a tendency to become more uniform and simpler and more like those used on saturated steam locomotives. On new locomotives, piston valves are exclusively used for the high-pressure cylinders and packings, with sliding joints and outside cooling for rods acted on by live steam. The area of the cylinder relief valves has also been increased. These are the only special arrangements, the necessity for which has been universally recognized.

"Some administrations use at the same time both inlet and air valves and by-pass. The usefulness of this double action does not appear to be yet completely established. Corliss and similar type valves and the unaflow arrangement have made no progress."

In general, the tendency is towards larger locomotives, but also towards refinement in design and increase in capacity. The accompanying tables give the main dimensions of a number of representative freight and passenger locomotives which have been built in the United States during recent years.

Soon after the United States Government assumed control of all the trunk line railways of the United States, December 28, 1917, as a war-time measure, the director-general of the railroad administration appointed a committee to standardize the specifications for locomotives, and as a result of conferences in which operating men, engineers, and manufacturers participated, twelve sets of specifications and designs for locomotives, divided among eight types, were developed. Orders were placed for locomotives with the three leading locomotive manufacturers of the United States, two of which, the Baldwin Locomotive Works and the American Locomotive Company, built some to each of the standard specifications, while the Lima Locomotive Works confined their activities to a single type. These types represented the best practice at the time they were developed, and there have been but few essential developments since. A number of them are summarized in the accompanying tables.

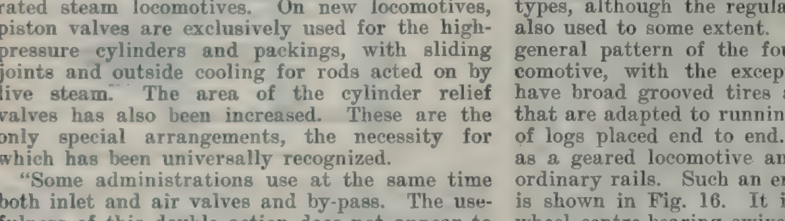

FIG. 16. GEARED LOCOMOTIVE FOR LOGGING RAILWAY.

European locomotives differ from those used in America chiefly in the following particulars: The American locomotive has a bar frame and carries its cylinders outside of the frame, while English and many European locomotives have a plate frame and usually carry the cylinders inside of the frame. The frame of the American engine usually rests on the wheels through the medium of equalizing springs, while equalizing springs are but seldom used on European engines. Eight-wheel tenders are almost universal in America, there being some twelve-wheel ones, while four-wheel and six-wheel tenders are used in Europe. The roomy cabs with seats for the engineman and fireman are peculiar to American engines.

Logging Locomotives. The locomotives ordinarily known as logging locomotives are of two types, although the regular main-line types are also used to some extent. One is built after the general pattern of the four-wheel switching locomotive, with the exception that the wheels have broad grooved tires a foot or so in width that are adapted to running upon a track formed of logs placed end to end. The other is known as a geared locomotive and is fitted to run on ordinary rails. Such an engine of the Shay type is shown in Fig. 16. It is built on three four-wheel centre-bearing swiveled trucks, the wheels of which are driven by bevel gearing attached to the right-hand wheels of each truck with steel pinions meshing into them, carried by a shaft running in bearings attached to the journal boxes, and extending from axle to axle of each truck. The power is communicated in these pinion shafts with flexible couplings extending from the engines, which are placed vertically on the side of the boiler. This arrangement leaves each truck free to adjust itself to curves and irregularities of the track. The use of this locomotive is confined to roads having heavy grades and sharp curves, and it is restricted to low speeds.

Rack Locomotives are used where the grades are too steep to be operated by the ordinary traction locomotive. The adhesion between the wheel and the rail of such an engine cannot be taken at more than 25 per cent of the weight on the drivers. Hence when the grade becomes so steep that the resultant of gravity acting parallel to the wheels becomes equal to 25 per cent of the weight on the driving wheels it will be impossible for the locomotive to advance. Such a grade is reached when the rise is 1320 feet to the mile. Practically it is much less than this. So on a grade of one-half of this the engine could at best only hold, not haul, itself and a load equal to its own weight. The weight of the locomotive (Fig. 17) is carried on smooth rails in the ordinary manner, and while the grade lies within the limits of its weight to overcome, it is propelled by driving wheels, like other engines. But when the grade becomes too steep the gear wheel is brought into mesh with a rack rail laid in the centre of the track between the other two.

2 MALLET COMPOUND ARTICULATED LOCOMOTIVE FOR SLOW, HEAVY, FREIGHT SERVICE

Gasoline engines are used to considerable extent as the motive power for single cars on branch lines. This class of traffic is also taken care of in many instances by gas-electric cars in which the motors are furnished with current from a generator mounted in the car and driven by a gasoline engine. In both of these types the driving power is applied to one truck only. To a limited extent both of these systems have been applied to locomotives for switching service, and there are also in limited use gasoline locomotive.

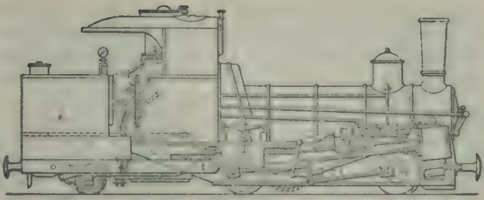

FIG. 17. LOCOMOTIVE FOR RACK RAILWAY.

Professor Stumpf, the inventor of the unaflow engine, has applied this type to locomotives, and in 1922 some 200 such locomotives were operating in Europe, while installations in the United

States had been planned. In this type used extensively in stationary engines the steam flows through each end of the cylinder in one direction only, so as to reduce the losses in heat transfers.

In Europe efforts have been made to use the steam turbine in connection with the locomotive. In Switzerland a Zoelly turbine had been fitted to a locomotive in the Winterthur Locomotive Works, while in Sweden the Ljungstroms Steam Turbine Company had equipped a locomotive for the Swedish State Railway with a machine of their design which was reported to save 52 per cent in fuel. In England a turbine has been fitted to a locomotive with an electric transmission gear by Sir W. G. Armstrong, Whitworth and Company. In Italy a Belluzo turbine had been used on a small switching locomotive, and with the experience gained a specific type of road locomotive was equipped. In connection with the necessity for economy in fuel, another European development was the application to locomotives of the Diesel internal

* Simple 101,300 lbs. Compound.

combustion engine, similar to that used on submarines, but up to 1922 only small special locomotives or motor cars drawing not more than one trailer had been constructed on this system.

Compressed-air locomotives are used for mine work and switching around shop plants, but the electric locomotive is preferred. Storage-steam or fireless locomotives are also used to some extent for switching about shops. See Fireless Engine. For electric locomotives see Electric Railways.

LO′COMO′TOR ATAX′IA (Neo-Lat., from Lat. *locus*, place + *motor*, mover, and Gk. ἀταξία, disorder, from ἀ-, α-, not + ταξία, *taxia*, order, from τάσσειν, *tassein*, to arrange), or Tabes dorsalis. A disease of the nervous system, commonly of the posterior root zones of the spinal cord, characterized by incoördination of movements and by sensory and trophic disturbances. The earliest account of the disease was given by Todd in 1847. Turck, in 1856, first described the pathological alterations in the spinal cord; and Romberg and Trousseau in 1858 further clarified the symptomatology. The clinical picture is not one of paralysis, but loss of power to order harmoniously the muscles that move the body and maintain equilibrium. It begins insidiously and grows slowly. The earlier symptoms are usually disorder of vision, a girdle sensation, with shooting pains through the limbs; increasing or perverted sensibility, and disturbance in the functions of the bladder and of the rectum resembling neuralgia or sciatica. Later, the patient feels that his walking is not firm and sure; that there is some soft substance between his feet and the ground; he walks with difficulty and with short, hurried steps; each leg is lifted well up, but as he moves it forward, it is thrown out from him, and the heel descends with force, while the sole comes awkwardly after it. He now requires the aid of vision to walk at all and looks steadily at his feet or at a point a little in front of them, and he cannot make a sudden turn without great risk of falling. If he stands erect with his feet together or nearly so, and closes his eyes, he begins to totter, and would fall if not supported (Romberg's sign). These phenomena are not primarily the result of weakness of motor power, but of defective muscular coördination. Diminished sensibility in the feet and legs is usual in this disease. The patellar reflex is lost. The upper limbs are sometimes affected, so that, though the hands retain all their natural muscular power, the sufferer cannot unfasten a button, or pick up a pin, or feed himself. As the disease progresses, this muscular incoördination (ataxia) increases until the person affected is unable to walk at all. Paralysis of various muscles may occur, notably of some of those of the eye. The involvement of the bladder produces a loss of the power of urination, and general weakness results in death. Although usually going to a fatal termination, the disease is sometimes arrested and appears to be quite conquered particularly in its earlier stages. In most cases it extends over several years. Locomotor ataxia arises from disease of a portion of the posterior spinal ganglia, later involving the posterior columns and the posterior nerve roots, which become atrophied and degenerated. The exciting causes are not well understood, but exposure to cold, overexertion, privation, intemperance, and mental anxiety have been suggested as probable. It is probable that syphilis (generally acquired, but sometimes hereditary) is the most important single cause, at least 70 to 95 per cent being due to this alone or to syphilis combined with alcoholism. Antisyphilitic treatment results in amelioration in many cases. It is more common among males than females. It is developed usually not till middle life, from the age of 30 to 50. Since the introduction of salvarsan better results are obtained. This drug is best given by injection directly into the spinal canal. Remarkable improvement has been noted in a considerable number of cases treated in this manner. Electricity has been recommended by eminent authorities. It is always necessary to attend carefully to the general health and regimen. Much can be done for the ataxia by systematic exercises carried out under a physician's instructions. Consult William Osler, *Practice of Medicine* (New York, 1912).

LOCO WEED. See Astragalus; Loco Disease.

LO'CRI, or Locri Epizephyrii. See Locris.

LO'CRIS (Lat., from Gk. *Λόκρις*, *Lokris*). A small district of ancient Greece (Map: Greece, Ancient, C 2). There was a legend which told of a King Locros, a descendant of Deucalion (q.v.), who ruled over the Leleges (q.v.) on the coast of the mainland opposite Eubœa, and whose wife, a daughter of the King of Elis, bore to Zeus a son Opus. Later, moved by the strife of his sons, Locros is said to have crossed the mountains to the southwest and to have formed a new settlement on the shores of the Corinthian Gulf. The Locrian tribes seem to have been forced asunder by the invasions from the north; in historic times two distinct tribes were known. The eastern Locrians, divided into the Opuntian Locrians and the Epicnemidian Locrians, dwelt opposite the island of Eubœa on the northeast coast of Greece. From these Locrians came Ajax, the son of Oïleus (q.v.). Their chief deity was Persephone. The western Locrians, called Ozolian Locrians, lived on the Corinthian Gulf, west of Phocis. Neither division played any prominent part in Greek history. Early in the seventh century B.C. a colony, probably of the Opuntian Locrians, settled at Cape Zephyrium in Magna Græcia, and a few years later moved to a site about 5 miles south of the modern Gerace, where they founded Locri Epizephyrii. This city never attained the prosperity of the great trading colonies, but seems to have been a prosperous farming community. It was celebrated for its severe but just code of laws, attributed to Zaleucus, who is said to have lived about the middle of the seventh century B.C. and to have been the first Greek to prepare a written code. So highly was his work esteemed that it is said to have remained unaltered for centuries. The Locrians won great fame by defeating the much more powerful city of Crotona (q.v.) in a bloody battle at the river Sagras, about 525 B.C., a victory which they ascribed to the personal intervention of the Dioscuri. The town was seized by the younger Dionysius, after his expulsion from Syracuse in 356 B.C., and ruled with the greatest tyranny until his return to Syracuse in 346 B.C., when the inhabitants rose and took a frightful vengeance on the members of his family who had been left behind. During the wars of Rome with Pyrrhus and Carthage the city was alternately occupied by the opposing parties, and its temple of Persephone was finally plundered by the Romans, who, however, made restitution later. Soon after, it seems to have declined in importance, but is mentioned by Procopius in the sixth century A.D. It was probably destroyed by the Saracens, about 915. In 1889 and 1890 excavations near Gerace brought to light the foundations of an Ionic temple, possibly that of Persephone or that of the Dioscuri. Consult *Römische Mittheilungen*, vol. v (1890) and *Antike Denkmäler*, i, 5 (1890). Excavations in 1890–91 yielded much more important results, such as archaic terra cottas, 14,000 *scyphi*, or cuplike vases, arranged in rows in tile-covered trenches, and important traces of the walls. In 1910 a small temple of Athene, a shrine of Persephone, and a pre-Grecian necropolis were discovered. Consult: *Notizie degli scavi*, for 1902, 1906, 1909, 1911, 1912; "Lokris" and "Lokroi Epizephyrioi," in Friedrich Lübker, *Reallexikon des klassischen Altertums*, vol. ii (8th ed., Leipzig, 1914).

LO'CUS (Lat., place). The place of all points satisfying a given condition. For example, the circumference of a circle whose centre is O and whose radius is r is the locus of all points satisfying the condition of being in the same plane and at a distance r from a fixed point O in that plane. In space the locus is the surface of a sphere of centre O and radius r. Instead of speaking of the locus of "all points," we may also speak of the locus of "a point" satisfying a given condition. Thus, the locus of a point in a plane at a distance d from the circumference of a circle of radius r is a pair of concentric circles of radii $r + d$ and $r - d$. In proving a theorem concerning the locus of points it is necessary and sufficient to prove two things—that any point on the supposed locus satisfies the given condition, and that any point not on the supposed locus does not satisfy the condition. A few important propositions of loci are: (1) the locus of points equidistant from two given points is the perpendicular bisector of the line joining them; (2) the locus of points equidistant from two given lines consists of the bisectors of their included angles; (3) the locus of points equidistant from three given points is the perpendicular to their plane passing through the centre of the circle on which they lie; (4) the locus of points the sum of whose distances from two fixed points is constant is an ellipse whose foci are the given points; (5) the locus of the vertices of constant angles subtended by a given line segment is an arc of which that segment is the chord; (6) if a pair of variable quantities, x, y, are connected by an equation, and each pair of values is represented by a point in a plane, these points will be on a definite curve called the locus or graph of the equation. (See Coördinates.) Thus, the study of curves by analytic methods is a development of the theory of loci. (See Curve.) The method of loci in pure geometry was extensively used by the Greek geometers, particularly Apollonius, Hippias, Eudoxus, Nicomedes, and Diocles. The methods of Apollonius were restored by Robert Simson in his *De Locis Planis* (1748), but as an analytic instrument the theory of loci dates from Descartes (1637).

LO'CUS DELIC'TI (Lat., place of crime or wrong). In criminal law, the place where a crime is actually committed. The question of *locus delicti* usually arises when a wrongful act is commenced in one jurisdiction and continued in another. For example, if goods are stolen in New Jersey and carried by the thief into Delaware, the larceny was committed in New Jersey, as the wrongful taking with intent to steal constitutes the crime. A State may make it a distinct statutory crime knowingly to bring stolen goods into the State; but in the absence of such a statute such a criminal could not be punished, except in the State where he originally stole the goods. However, if a man stands in New Jersey and shoots another across the line in New York, he is guilty of murder in the latter State, as the killing was in fact committed there, although the criminal act was initiated in New Jersey.

The phrase is also used in the law of torts, but is not of as great importance as in criminal law, as jurisdiction of civil causes merely depends, not on the place where the act was committed, but on jurisdiction over the parties. See Crime; Jurisdiction.

LO'CUS PŒ'NITEN'TIÆ (Lat., place of repentance). In the civil law, the period of time within which a person may retract an offer or withdraw from a contemplated bargain or contract. See Contract.

LO'CUST (from Lat. *locusta*, locust, lobster). Any orthopterous insect of the family Acridiidæ. Much confusion has arisen in the use of this term, for two reasons: the family Locustidæ, including the typical genus *Locusta*, are popularly termed "long-horned grasshoppers"; and, on the other hand, "locust" is given popularly (in the Orthoptera) only to members of the Acridiidæ, which are also termed "short-horned grasshoppers." (See Grasshopper.) In the United States a further confusion arises from the fact that the term "locust" is applied to any member of the hemipterous family Cicadidæ, which includes the so-called seventeen-year "locust" or periodical cicada (see Cicada and Hemiptera) and the common dog-day harvest fly. The name, however, should be restricted to the insects of the family Acridiidæ and is so used by all English-speaking people except in portions of the United States.

Locusts may be distinguished from the long-horned grasshoppers and the crickets, such as the common *Anabrus simplex*, by the relatively short antennæ, the short ovipositor of the female, and the long hind legs with thickened thighs. They stridulate by the friction of the rough hind legs against the wing covers, this method differing from the stridulation of the katydids and crickets. (See Katydid; Cricket.) The wing covers are leathery and narrow, the wings themselves being broad, and when at rest folded like a fan.

The power of flight in locusts varies with the species. Those capable of sustaining prolonged flight have large tracheal dilatations within the body. The species of greatest economic importance in the United States are the Rocky Mountain locust (*Melanoplus spretus*), the red-legged locust (*Melanoplus femur-rubrum*), the lesser migratory locust (*Melanoplus atlantis*), the American locust (*Schistocerca americana*), and the differential locust (*Melanoplus differentialis*). The Old World migratory locusts belong principally to two species, *Pachytylus migratorius* and *Acridium peregrinum*. A South American species of the genus *Acridium* frequently inflicts great damage upon crops in Argentina and Chile, while in South Africa a migratory locust comes down from the north in swarms and destroys the crops of the settlers. These few species, possessing great powers of multiplication and extended powers of flight, have been classed among the world's historical scourges. Early incursions in Europe and north Africa are mentioned by Orosius and St. Augustine, the latter recording a plague in Numidia which resulted in the death of 800,000 men. Pliny states that locusts came over in great swarms from Africa to Italy in his time. Incursions as far north as Germany occurred in 1333 lasting until 1336, 1475, 1527, 1543, 1636, 1686, and at intervals until 1856–59.

The Rocky Mountain locust of the United States formerly bred over vast areas in the Northwest and at intervals migrated in immense swarms for hundreds of miles beyond its usual habitat. In 1818 and 1819 that part of the country now known as Minnesota was covered by vast swarms; in 1820 the western part of Missouri was ravaged; in 1842 they again appeared in Minnesota and Wyoming, and in 1845 in Texas and again in 1849. They appeared in Utah nearly every year from 1851 to 1877, and a portion of Utah at one time was included in the permanent breeding grounds of this species. An unusual locust year was 1856, when the insects swarmed over Kansas and Nebraska, the western counties of Missouri and northeastern Texas, and in Iowa, Minnesota, Colorado, and Utah. In 1870 to 1871 they again began to increase, and in 1873 were very injurious. The most disastrous locust year known in the United States, however, was 1874, when enormous swarms invaded the settled portions of the Mississippi valley west of the ninety-fourth meridian. Colorado, Nebraska, Kansas, Wyoming, Dakota, Minnesota, Iowa, Missouri, New Mexico, Indian Territory, and Texas were overrun by swarms from the Northwest, mainly from Montana and British America. The loss in this region was estimated at $50,000,000 in the actual destruction of crops. In 1875 the young insects hatched in immense numbers over an area embracing portions of Nebraska, Kansas, and Missouri, entailing destitution and suffering among a population of 750,000 people. In 1877 the young insects died in great numbers, and those which acquired wings flew towards the Northwest in the direction of Dakota and Montana, the region of the permanent breeding grounds. The district in which the insect was considered to breed permanently was mapped by the United States Entomological Commission in 1877. It was stated that the area comprised about 300,000 square miles. The most favorite breeding places in this area were the river bottoms and the sunny slopes of uplands or the grassy regions among the mountains. At the same time a "subpermanent" breeding region in which the insects breed more or less continuously was also mapped out. When the Entomological Commission finished its labors in 1879, these conclusions were practically confirmed. Since that time, however, much of that region has been greatly changed in character by settlement and by the introduction of agriculture. The result has been that the permanent breeding grounds of the Rocky Mountain locust have been greatly restricted, and in fact it has practically been driven beyond the borders of the United States, and now breeds freely only in portions of British Columbia. From those grounds, however, occasional swarms fly south into the Northwestern States and do more or less damage for a single season, as has been the case in restricted localities in Minnesota and North Dakota.

The eggs of locusts are usually laid in the ground. With the Rocky Mountain species from 20 to 35 are laid together in a compact mass covered with a pod. The locust itself occupies seven weeks from the time of hatching in attaining its full growth. The locusts of the Old World have been known to fly to Central Europe from their permanent breeding grounds in Central Asia. In North America they often extend their flights over a distance of from 1000 to 2000 miles, or from Montana to Missouri and even to Texas. Flight takes place during the day and ends towards sundown. The rate of travel varies from three to 20 miles an hour, depending upon the wind. The height at which the migrating swarms move differs greatly, according to the direction and height of the air currents. They have been noticed, e.g., flying far above the summit of Parry's Peak, an elevation of more than 13,000 feet.

The best measures advised for their destruction are harrowing and late fall plowing for the destruction of the eggs, crushing of the newly hatched individuals between rollers, and especially the collecting of the young individuals by an apparatus consisting primarily of a coal-oil pan either dragged along the ground or mounted upon wheels. Of late years a good remedy has been discovered in the use of a mash of bran and arsenic, which is distributed in little moist masses about the infested fields. The locusts are fond of this mixture, and it is fatal to them. Good results have been reached in South Africa, and to a much lesser degree in the United States, during the past few years, by distributing a pathogenic fungus of the genus *Sporotrichum*, which kills the locusts when they occur in swarms. Locusts are also subject to several other diseases; there is a fungus of the genus *Mucor* which undoubtedly kills them, and another (*Empusa grylli*) frequently destroys them in great numbers. They have many natural enemies among birds and parasitic insects, including hairworms (see HAIRWORM), and insects that devour their eggs. Locusts are eaten in many countries, roasted or fried in butter. They are also preserved in brine or dried in the sun. They thus appear in the markets of Arabia, Syria, Egypt, and Madagascar, and are even exported as an article of commerce. They are also candied and eaten as a delicacy in China, and in the Philippines they frequently form an important article of diet among the poorer classes.

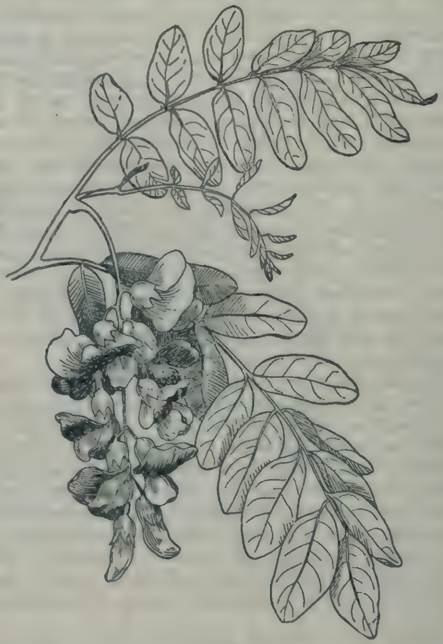
Consult: *United States Entomological Commission, Reports First, Second, and Third* (Washington, 1877, 1879, and 1882); Munro, *The Locust Plague and its Suppression* (London, 1900); also publications of the United States Department of Agriculture, Bureau of Entomology.

LOCUS′TA, or **LUCUS′TA**. A female poisoner at Rome, used by Agrippina to poison Claudius and by Nero to destroy Britannicus. For the latter deed she was rewarded by Nero, but was executed under the Emperor Galba. Consult Juvenal, i, 71, and the editors there.

LOCUST BIRD. A bird notable for feeding upon locusts, especially a South African grackle (*Creatophora carunculata*). In the same region a white stork is called "great" locust bird, and one of the pratincoles (*Glareola nordmanni*, or *melanoptera*) "little" locust bird. The great swarms of locusts that frequently visit the South African plains are followed and attacked by the pratincoles in revolving flocks; their very curious actions are described at length by Layard, in *Birds of South Africa* (London, 1867). In India the name is suitably given to a starling, the familiar rose-colored pastor. See PASTOR.

LOCUST BORER. See CERAMBYCIDÆ.

LOCUST TREE. A name given to various trees of the family Leguminosæ. The carob tree (*Ceratonia siliqua*) is often so called in the countries bordering on the Mediterranean. The locust tree of America (*Robinia pseudacacia*), also called the false acacia or thorn acacia, and on the continent of Europe very generally the acacia, is valuable. It is of rapid growth and is very ornamental, especially when in flower. On account of its rapid growth, spiny branches, and ability to withstand trimming, it is considered a valuable hedge tree. Its generic name is derived from John Robin, who is said to have introduced the tree into France about the year 1600. It succeeds well as a forest tree in Europe except in the north, where it suffers from frost. Locust wood is compact, hard, takes a good polish, and is useful for all purposes in which great strength and especially toughness are required, qualities which make it valuable in shipbuilding, for which large quantities are used. It is also valuable for making the cogs of wheels. In the United States the *Robinia* attains its best development in Kentucky, Tennessee, and vicinity, where in rich soil it reaches 70 to 80 feet and 3 feet in diameter. The tree is especially subject to insect injuries, on which account it is often condemned. The clammy locust, *Robinia viscosa*, and the bristly locust, or rose acacia, *Robinia hispida*, American species, are planted extensively, especially the latter, which is a shrub 3 to 10 feet high. The honey-locust tree of America is a *Gleditschia*. The locust tree of the West Indies (*Hymenæa courbaril*) is a gigantic tree, whose pods supply a mealy nutritious substance in which the seeds are embedded. It is sweet and pleasant, but reputed as inducing diarrhœa when recently gathered. A fermented decoction is used as beer. See CAROB; HONEY LOCUST; and Plate accompanying LIME TREE.



LOCUST.

LOCUST-TREE INSECTS. The insects that attack the locust (*Robinia pseudacacia*) are numerous, and the tree suffers from some of them very seriously in certain parts of the United States. Forty-one species of insects feeding upon this tree are treated in Packard's *Report on Forest Insects*. Of those which affect the trunk, the locust borer, the larva of a long-horned beetle (*Cyllene robiniæ*), is one of the most important. It is a black beetle with yellow transverse bands, and, like its near relative (*Cyllene pictus*) which infests the hickory, has a superficial resemblance to certain wasps and has thus been cited as a case of protective mimicry. Another borer, the larva of a sesiid moth (*Sciapteron robiniæ*), is destructive to locust trees as well as to poplars on the Pacific coast; and the locust twig borer (*Ecdytolopha insiti-*

ciana) causes a thickened growth of certain twigs for a distance of from 1 to 3 inches. The adult of this species is a tortricine moth. (See LEAF ROLLER.) Many of the leaf feeders are leaf rollers and leaf miners, but the larva of a very striking butterfly known as the "locust skipper" (*Eudamus tityrus*) has this habit also. A leaf-mining beetle (*Odontota scutellaris*) disfigures the leaves with its larval mines throughout the Eastern States. The larva of the locust saw fly (*Nematus similaris*) feeds upon the leaves and occasionally defoliates trees. Consult A. S. Packard, *Fifth Report of the United States Entomological Commission* (Washington, 1890).

LO′CY, WILLIAM ALBERT (1857–). An American zoölogist. He was born at Troy, Mich., graduated from the University of Michigan in 1881, and studied also at Harvard (1884–85), Berlin (1891), and Chicago (Ph.D., 1895). He was professor of biology (1887–89) and of animal morphology (1889–96) at Lake Forest University, professor of physiology at Rush Medical College, Chicago (1891), and professor of zoölogy at Northwestern University after 1896. He became known especially for his researches in embryology and animal morphology. In 1902–03 he made investigations at the Naples zoölogical Station. He is author of *Biology and its Makers* (1908).

LODE (AS. *lād*, way, course, from *līpan*, Goth. *leipan*, OHG. *līdan*, to go, to travel). A miners' term for veins in which minerals occur. They are crevices, more or less vertical, produced by contraction or mechanical disturbance of the rock, which have subsequently been filled with metallic ores. See ORE DEPOSITS; MINING; COMSTOCK LODE.

LO-DE′BAR. A place in Gilead which (if the reading be correct) was the residence of Machir, son of Ammiel, with whom Jonathan's son, Mephibosheth, lived at the beginning of David's reign (2 Sam. ix. 4–5). Machir and Lo-debar are mentioned again in chap. xvii. 27 in connection with David's flight in consequence of Absalom's rebellion. Probably the same place is meant in Josh. xiii. 26 (cf. Revised Version, margin), and some authorities think it is referred to in Amos vi. 13. The location has not been identified. A village, Idbar, 7 miles east of Umm Kais (Gadara), has been suggested.

LODEMAN, lō′de-mȧn, ERNEST GUSTAVUS (1867–96). An American horticulturist and author. He was born in Neuchâtel, Switzerland, but came to America with his parents in 1870, his father having been appointed professor of modern languages in the Michigan State Normal School. He was graduated from the Agricultural College of Michigan in 1889. In 1890 he became assistant to Prof. L. H. Bailey in Cornell University and shortly afterward instructor in that institution. While there he originated the spray calendar, a placard which gives in concise form approximate dates for spraying insect and fungous enemies of various crops, together with formulæ for preparing the principal fungicides and insecticides. He also published the results of many investigations in bulletins of the Cornell Agricultural Experiment Station. *The Spraying of Plants* (New York, 1896), his only book, was prepared after comprehensive field work, and embraces not only the results of his exhaustive studies at home and abroad, but all that was then considered valuable on the subject.

LO′DER'S GAZELLE. See GAZELLE.

LODE′STAR, LOADSTAR (*lode*, AS. *lād*, way, course + *star*), LEADING STAR, or GUIDING STAR. Terms applied to the polestar, which is the last star in the tail of the Little Bear. It is a star of the second magnitude, located about 1° 20′ from the North Pole.

LODE′STONE, or **LOADSTONE.** See MAGNETITE.

LODÈVE, lō′dĕv′. The capital of an arrondissement in the Department of Hérault, France, situated in a beautiful valley on the Ergue, 36 miles northwest of Montpellier by rail (Map: France, S., H 5). It retains its mediæval walls, has a fortified cathedral dating from the thirteenth century and a communal college. It is noted for its manufactures of army clothing and woolens, also chemicals. Lodève is the Gallic Luteva and the Roman Forum Neronis. Previous to 1790 it was the seat of a bishop. Cardinal Fleury was a native of Lodève. Pop., 1911, 6315.

LODGE, EDMUND (1756–1839). An English biographer and historian, born in London. He held various heraldic positions, and his studies in that field include: *Illustrations of British History, Biography, and Manners in the Reigns of Henry VIII, Edward VI, Mary, Elizabeth, and James I* (1791), a selection from contemporary manuscripts in the College of Arms; *Portraits of Illustrious Personages of Great Britain* (1814), a work costing more than £40,000; and *The Genealogy of the Existing British Peerage* (1832; last ed., 1859). The present *Lodge's Peerage* grew from an *Annual Peerage and Baronetage* (4 vols., 1827–29), reissued in 1832 as the *Peerage of the British Empire*, the work of the Misses Anne, Eliza, and Maria Innes, to whom Lodge lent the use of his name.

LODGE, GONZALES (1863–). An American classicist, born at Fort Littleton, Pa. He received the bachelor's degree from Johns Hopkins in 1883 and his doctorate from the same university in 1886. From 1889 to 1900 he was professor of Latin in Bryn Mawr, and he then became professor of Greek and Latin in Teachers College, Columbia University. He was joint author of the revised edition of the Gildersleeve-Lodge *Latin Grammar* (1894), editor of Plato's *Gorgias* (1891), and managing editor of the Gildersleeve-Lodge *Latin Series*. Between 1901 and 1914 seven parts had appeared of his great *Lexicon to Plautus*, in which every word is treated with minutest reference to all the variant manuscript readings in the passages in which it occurs, with frequent references also to articles and books in which the words have been discussed. In 1907 he published *The Vocabulary of High School Latin*, a study of the words, approximately 2000 in number, of most frequent occurrence in the Latin usually read in preparation for college, and so of greatest value to students. From 1907 to 1913 he was editor in chief of *The Classical Weekly*.

LODGE, HENRY CABOT (1850–). An American legislator and historical writer, born in Boston, May 12, 1850. He graduated from Harvard College in 1871 and from Harvard Law School in 1874, and two years later, after graduate work in history, received the degree of Ph.D. From 1873 to 1876 he edited the *North American Review*, for three years he lectured on American history at Harvard, and from 1879 to 1881 he was editor of the *International Review*. About this time he entered political life.

He served in the Massachusetts House of Representatives (1880–81), as a Member of Congress (1886–93), and thereafter as United States Senator, being reëlected in 1899, 1905, and 1911. As a politician, he early became prominent for his insistence upon laws to safeguard the franchise and upon the necessity for the restriction of immigration by the requirement of educational qualifications. During the Spanish-American War he strongly supported the administration. A Republican of conservative type, he was a delegate to a number of the party's national conventions and was permanent chairman in 1900 and 1908. In 1903 he was appointed to the Alaskan Boundary Commission and in 1907 to the United States Immigration Commission. With his son-in-law, Representative A. P. Gardner, he led the movement in Congress (1914–15) for an investigation of the military preparedness of the United States. His writings brought him membership in the American Academy of Arts and Letters. These include: *Short History of the English Colonies in America* (1881); *Studies in History* (1884); *History of Boston* (1891); *Historical and Political Essays* (1892); *Speeches* (1895); *Hero Tales from American History* (1895), with Theodore Roosevelt; *Certain Accepted Heroes and Other Essays* (1897); *The Story of the Revolution* (2 vols., 1898); *The War with Spain* (1899); *A Frontier Town and Other Essays* (1906); *Speeches and Addresses* (1910); *One Hundred Years of Peace* (1913); *The Democracy of the Constitution* (1914). He also published the *Life and Letters of George Cabot* (1877) and a volume of *Essays on Anglo-Saxon Land Laws*, and edited the works of Alexander Hamilton (1885). For the "American Statesmen Series" he prepared the lives of Hamilton (1882), Webster (1883), and Washington (2 vols., 1889). His *Early Memories* (1913) is, so far as it goes, autobiographical, and interesting in its personalia regarding New England notables of a generation earlier than the author's. See SUPPLEMENT.

LODGE, SIR OLIVER (JOSEPH) (1851–). An English physicist, philosopher, and student of psychical phenomena. He was born June 12, 1851, at Penkhull, Staffordshire. Upon the completion of his grammar-school education he at first entered business life, but by studying evenings he was able to matriculate and pursue courses at University College, London, where he graduated B.Sc., taking honors in physics, and where, after further study in Prof. Carey Foster's laboratory, he received the degree of D.Sc. and became assistant professor of physics. When University College, Liverpool, was founded, Lodge became professor of physics (1881) and was connected with that institution until 1900, when he became principal of the University of Birmingham. In 1903 he was Romanes lecturer at Oxford. Professor Lodge's researches in electricity dealt especially with alternating currents, lightning discharges, and the physics of the ether. In the course of his experiments with lightning conductors he was able to discover oscillations and waves in conductors. Studying the high-frequency oscillations of a Leyden jar, he was able to create stationary electrical oscillations on wire, and, as he was seeking to demonstrate Maxwell's theoretical observations, it is more than probable that he would have observed these waves in air if he had not been anticipated by Hertz (q.v.). However, in 1894 he discovered that these waves would cause filings of metals to cohere or alter their arrangement and electrical resistance, and was thus able to construct the *coherer*, which plays so important a part in wireless telegraphy (q.v.). This invention was also made independently by Edouard Branly, of Paris; but Lodge's work in this field was followed by other discoveries which brought about substantial advances in wireless telegraphy. His researches on lightning led to the revision of many ideas which had long been held on this subject, and his work on *Lightning Conductors and Lightning Guards* is considered one of the most valuable works of its kind. In addition to his activities in physical science, Sir Oliver interested himself in various educational reforms and in later years took part in philosophical and religious discussion and investigation. He wrote considerably on the relation of modern views of science to religion and became interested in psychical research. At various times he stated publicly his belief in a life after death, and his expectation that eventually unhampered communion would be possible between living persons and the spirits of the dead. From 1901 to 1904 he was president of the Society for Psychical Research. He received the Rumford medal of the Royal Society in 1898, in 1902 was knighted, was president of the Physical Society of London in 1899–1900, and president of the British Association in 1913–14; and he received honorary degrees from Oxford, Cambridge, Victoria, Liverpool, St. Andrews, Glasgow, and Aberdeen. His writings include: *Elementary Mechanics* (1877); *Modern Views of Electricity* (1889 and later eds.); *Lightning Conductors and Lightning Guards* (1892); *Pioneers of Science* (1893); *The Work of Hertz and Some of his Successors* (1894); *Modern Views on Matter* (1903); *Life and Matter* (1905); *The Substance of Faith* (1907); *Man and the Universe* (1908); *Immortality of the Soul* (1908); *Ether of Space* (1909); *The Survival of Man* (1909); *Parent and Child* (1910); *Modern Problems* (1912); *Continuity* (1914).

LODGE, THOMAS (c.1558–1625). An English poet, dramatist, and miscellaneous writer, born in or near London. He graduated B.A. from Trinity College, Oxford (1577); was admitted as law student at Lincoln's Inn (1578); after some experience in the army, made voyages to the Canaries (1588) and to South America (1591); studied medicine, it is said, at Avignon (1600), and received the Oxford M.D. (1602). He died in Old Fish Street, London. His chief writings comprise: *A Defence of Plays* (?1580), a sharp retort to Stephen Gosson's *School of Abuse; An Alarum against Usurers* (1584); two plays, *The Wounds of Civil War* (1594) and, in conjunction with Robert Greene, *A Looking Glass for London and England* (1594); several romances, among which are *Rosalynde* (1590) and *Life of William Longbeard* (1593); translations of Josephus (1602) and of Seneca (1614); *Glaucus and Scilla* (1589, in a volume entitled *Scillaes Metamorphosis*), probably the model of Shakespeare's *Venus and Adonis; A Fig for Momus* (1595), a collection of satires, epistles, and eclogues; and a choice volume of poems called *Phillis* (1593). Lodge was one of the most graceful lyricists of the Elizabethan period. His *Rosalynde*, a beautiful pastoral, interspersed with some of his best verse, was the basis of Shakespeare's *As You Like It*. Consult: *Works*, all but translations, edited by E. W.

Gosse for the Hunterian Club, Glasgow (4 vols., 1878–82); J. A. A. Jusserand, *English Novel in the Time of Shakespeare*, translated from the French by Elizabeth Lee (Paris, 1890); J. A. Symonds, *Shakespere's Predecessors in the English Drama* (new ed., London, 1900); G. E. B. Saintsbury, *History of Elizabethan Literature* (ib., 1906).

LODGED (from *lodge*, OF., Fr. *loger*, to house, from *loge*, lodge, from ML. *lobia, lobium, laubia*, portico; ultimately connected with Eng. *lobby*). In heraldry, a term applied to a beast of chase, as a stag, when lying down with its head erect. A beast of prey in the same position is said to be couchant. See HERALDRY.

LODGING HOUSES. Houses which provide shelter for homeless people. The rapid and continuous increase of the floating population in large cities, due to the steady drift of low-grade labor to the cities, has accentuated the problem of lodging houses as distinguished from the tenement problem. This undomiciled population is a fruitful cause of disorder. At first America attempted to solve the problem by allowing the homeless to find shelter in the police stations. The buildings were ill adapted for the purpose, decent sanitary conditions usually impossible, and the general situation so demoralizing to the self-respecting laborer that the practice is now forbidden in most cities. Various rescue missions have conducted houses, often furnishing a free breakfast in addition to the night's lodging. In all the large cities there are many places where lodging and breakfast can be had for a pittance; but these places are run for gain, and conditions are often very bad. New York has some 105 such houses, with beds for 16,000.

There is a general sentiment that decent accommodations should be furnished the homeless, and in most cities efforts are being made to substitute sanitary houses for the filthy accommodations now so common. The most striking examples in the United States of model lodging houses are the two Mills hotels, in lower New York City, established by the late D. O. Mills. They accommodate 2250 men. Each lodger has a private room at a cost of 20 or 40 cents per night, with the privilege of free baths and use of laundry. Large, well-equipped reading, writing, and game rooms are provided. The enterprise has paid a fair return on the capital invested.

Boston, New York, Chicago, and other cities have established municipal lodging houses, where those who cannot pay for shelter may obtain lodging and breakfast in return for a few hours of labor, usually sawing and splitting wood. An agent investigates the stories of the men and assists in securing regular employment. No one may remain more than two or three nights consecutively without a good reason. In several cities, as Philadelphia and New York, similar institutions are maintained by charity organization societies, Salvation Army, etc. In some of the Salvation Army shelters a charge of 10 cents is made for lodging in a dormitory, and 15 cents for a separate room, bread and coffee being furnished for breakfast.

Most of the British municipalities have lodging houses. On the Continent Paris conducts seven establishments (*refuges de nuit*), three for men and four for women, which combine workshops with shelter. In the principal shelter for men, the Asile Nicolas Flamel, simple employment is given in a connected workshop with wages from two to three francs daily. These are accumulated until the worker leaves the establishment. Endeavors are made to secure employment outside. In Germany there are many private institutions, often carrying on some simple manufacture (brooms, etc.), at which homeless men and women may find shelter and a chance to work. The Christliche Hospize in the larger cities provide comfortable shelter at very low cost to working men. Berlin conducts a municipal night shelter where any penniless person may be received on five successive days five times in the course of three months. Soup and bread are provided at night and morning. See HOUSING PROBLEM.

Consult: *Charities Review*, vol. i (New York); "Floating Populations," *Annals of the American Academy of Social and Political Science*, vol. x; Jacob Riis, *The Children of the Poor* (New York, 1902); *Schlafstellenwesen und Ledigheime* (Berlin, 1904); Raymond Robins, *What Constitutes a Municipal Lodging House* (New York, 1904); W. H. Dawson, *The German Workman* (London, 1906).

LODGINGS. Furnished rooms or apartments which are let by special agreement, and in which the lodger gets no property right or interest, but merely the privilege of use and occupation under the terms of his contract. The relation of landlord and tenant does not exist between a keeper of lodgings and a lodger. One of the important distinctions is that a lodger has merely a personal action for damages for breach of contract against the proprietor of the lodgings in case the latter evicts him contrary to their agreement; whereas a tenant can enforce his property rights by an action to recover the actual possession of the premises if he is wrongfully evicted by his landlord or any other person. Unless particular rooms or apartments are specially designated in the agreement between the proprietor and a lodger, the latter may be assigned or changed to any room in the same house of the general character and class as that for which he bargained. The proprietor of lodgings is not, like an innkeeper, obliged to receive every person who applies to him, but may select his lodgers as he sees fit, and make such terms as may be satisfactory to both parties; nor is he absolutely responsible for the baggage and effects of his lodgers, but is liable only for loss resulting from his negligence or that of his servants. In the absence of statute he has no lien on the property of the lodgers in his house for the amount due him, but in New York and several other jurisdictions, lodging-house and boarding-house keepers possess such a lien. The keeper of a lodging house has the legal possession, care, and custody of his whole house and of every room; and it has been held that a lodger is not entitled to maintain an action against a stranger who invades his room, as that right is in the proprietor. A lodging house proper differs from a boarding house in that no meals are furnished to the lodgers as such. Boarders are, however, usually lodgers also, and therefore the term "boarder" is popularly employed to designate one who is entitled to meals and lodgings at the same house. See BOARDING HOUSE; INN; INNKEEPER; LANDLORD AND TENANT; LIEN; and consult the authorities referred to under CONTRACT; BAILMENT; ETC.

LODI, lō′dē. An episcopal city in the Province of Milan, Italy, 20 miles southeast of the city of Milan, on the Adda (Map: Italy, B 2).

It has a cathedral erected in 1158, containing numerous sculptures, and the fine fifteenth-century church of the Incoronata, an edifice in the Renaissance style and adorned with valuable paintings by the Piazza family and four altar pieces by Calisto Piazza. Its schools include a Gymnasium, a seminary, a technical school, and a teachers' institute, and there are a library and a lyceum. The district is one of the most extensive cheese-producing centres in the world; the manufactures include linen and woolen goods, silk, cement, pottery, and leather. Here, on the 10th of May, 1796, Napoleon won his celebrated victory over the Austrians which gained for France the possession of Lombardy. The ruins of the old Roman colony of Lodi Vecchio lie 4 miles west. Pop. (commune), 1901, 27,811; 1911, 28,032.

LODI. A city in San Joaquin Co., Cal., about 35 miles south of Sacramento, on the Mokelumne River, and on the Southern Pacific and the Central California Traction Company railroads (Map: California, D 4). Features of interest are the Union High School, a Carnegie library, and the municipal building. Lodi is situated in a rich fruit country, its chief industrial establishments being fruit-packing sheds, fruit-juice factories, and a cream-of-tartar factory. The electric-light plant and water works are owned and operated by the municipality. Pop., 1910, 2697.

LODI. A borough in Bergen Co., N. J., 2 miles (direct) northeast of Passaic, on Saddle River, and on the New York, Susquehanna, and Western Railroad (Map: New Jersey, D 2). The dyeing of silk and cotton goods is the principal industry, and there are also bleaching works and manufactures of rubber goods and plantation car equipments. The water works are owned by the borough. Pop., 1900, 1917; 1910, 4138.

LOD'OME'RIA. The Latin name of a mediæval Slavic principality, whose history forms part of that of Galicia (in Austria-Hungary). See Galicia.

LODZ, lôdz; *Polish pron.* lụj. The capital of the district of Lodz, in the government of Piotrkow, and next to Warsaw the most important town in Russian Poland. It is situated on the Ludka, 87 miles by rail southwest of Warsaw, and occupies with its suburbs an area of nearly 11 square miles (Map: Russia, A 4). It is primarily a manufacturing city, devoid of any architectural beauty. It is well supplied with educational institutions, which include two Gymnasia, a technical institute, three theatres, and several libraries. In the manufacturing of textiles Lodz holds the foremost position in Russian Poland. The industry is of comparatively recent origin, the first textile mills having been founded there in 1815. There are at Lodz upward of 650 establishments, having an annual output valued at $75,000,000. Cotton goods and woolens are the principal products, but there are also manufactured linen, silk goods, machinery, boilers, chemicals, beer, etc. The textile industry is chiefly in the hands of the Germans, to whom the city is mainly indebted for its present position. In 1860 Lodz had only 32,600 inhabitants; in 1885, 113,413; and in 1912, 450,604. The majority of the inhabitants are Poles, Germans, or descendants of Germans, and Jews. Lodz was occupied by the Germans in the early part of the European War which started in 1914, but they were compelled to evacuate the city by a superior Russian army. A month later it was retaken by the Germans after a destructive bombardment. They immediately strongly fortified it and used it as a base for later drives on Warsaw. See War in Europe.

LOEB, lẽb, Jacques (1859–). An American physiologist and experimental biologist. Born in Germany, he graduated from the Ascanisches Gymnasium in Berlin, and studied medicine at Berlin, Munich, and Strassburg, receiving the degree of M.D. at Strassburg in 1884. Between 1886 and 1891 he was assistant in physiology at the universities of Würzburg and Strassburg, and a research student at the Naples Zoölogical Station. He then came to the United States and was associate professor of biology at Bryn Mawr College (1891–92); assistant, associate, and full professor of physiology and experimental biology at the University of Chicago (1892–1902); professor of physiology at the University of California (1902–10); and thereafter head of the Department of Experimental Biology at the Rockefeller Institute, New York. He received an honorary D.Sc. from Cambridge University, M.D. from Geneva, and Ph.D. from Leipzig, all in 1909. Professor Loeb's special field is comparative physiology and psychology. He did pioneer work on artificial parthenogenesis and in an analysis of the process of fertilization of the egg. Among his important papers and books are: *The Heliotropism of Animals and its Identity with the Heliotropism of Plants* (1890); *Physiological Morphology* (vol. i, 1891; vol. ii, 1892); *Comparative Physiology of the Brain and Comparative Psychology* (1900); *Studies in General Physiology* (2 vols., 1905); *Dynamics of Living Matter* (1906); *Mechanistic Conception of Life* (1912); *Artificial Parthenogenesis and Fertilization* (1913); and numerous papers on physiology and experimental biology.

LOEB, James (1867–). An American banker, born in New York City. In 1888 he graduated from Harvard University and from then until 1901, when he retired, he was a member of the banking firm of Kuhn, Loeb & Co. He became a member of the English Society for the Promotion of Hellenic Studies. His extensive collection of Aretine pottery was placed in the Fogg Museum at Harvard. In 1911 plans were matured for the publication of the Loeb Classical Library, a library of some 300 volumes of translations from Greek and Latin authors, with the help of funds supplied by Mr. Loeb. For these plans, consult the article "Philology, Classical," in the New International Year Book for 1911; for the progress made by the library, consult id., 1912 et seq.

LOEB, Leo (1869–). An American pathologist, born in Germany. He studied at the universities of Heidelberg, Berlin, Zurich, Basel, and Freiburg, and in 1903 he was a research fellow at McGill University, Canada. He served as adjunct professor of pathology at the University of Illinois in 1900–01, as experimental pathologist of the New York State Pathological Laboratory in 1902, and assistant professor of experimental pathology at the University of Pennsylvania in 1904–10. In the latter year he became director of the pathological department of the Barnard Skin and Cancer Hospital at St. Louis. In 1911 he was president of the Society for Cancer Research and in 1915 president of the American Association of Pathologists and Bacteriologists. He published *The Venom of Heloderma* (1913).

LOEB, Louis (1866–1909). An American figure painter and illustrator, born in Cleveland, Ohio. He was a pupil of Gérôme in Paris and afterward settled in New York City and became an associate of the National Academy of Design and a member of the Society of American Artists in 1900. His subjects are usually landscapes, with figures, treated in an agreeable, decorative manner, with considerable poetic feeling, but with an almost academic completeness which sometimes destroys the personal note. The best known of his works include: "Temple of the Winds" (1898, Metropolitan Museum); "The Breeze" (1900); "The Joyous Life" (1903); "The Dawn" (1903), which won the Webb prize; "The Siren" (1905); portrait of Eleanor Robson (1905); "Miranda" (1906, Metropolitan Museum, New York); "The Summit" (1907); Princess Zomona (1908). He received the second Hallgarten prize of the National Academy of Design (1902) and two silver medals at St. Louis (1904).

LOEB CLASSICAL LIBRARY. See Loeb, James.

LOEBELL, lẽ'bel, Johann Wilhelm (1786–1863). A German historian, born in Berlin and educated at Heidelberg and at Berlin under Wolf and Böckh. From 1814 to 1829 he taught in the military academies at Breslau and Berlin and then became professor of history at Bonn. His best-known work is the revision of Becker's *Weltgeschichte* (1836–38). He also wrote: *Gregor von Tours und seine Zeit* (2d ed., 1869); *Weltgeschichte in Umrissen und Ausführungen*, part i (1846); *Die Entwicklung der deutschen Poesie von Klopstocks ersten Auftreten bis zu Goethes Tode* (1856–65); and an anonymous attack on Ultramontanism, *Historische Briefe* (1861). Consult Bernhardt and Noorden, *Zur Würdigung Loebells* (Brunswick, 1864).

LOEFFLER, lĕf'lẽr, Charles Martin (1861–). An American composer, born at Mühlhausen (Alsace). He received his musical education in Paris and Berlin. On the violin his teachers were Léonard, Massart, and Joachim, in composition Guiraud and Kiel. He began his career as a violinist in Pasdeloup's orchestra. In 1881 he came to America, and when the Boston Symphony Orchestra was founded, in 1883, he was appointed to share the first desk of the violins with the concert master, a position which he filled for 20 years. In 1903 he resigned in order to devote his entire time to composition. As a composer, he is remarkable rather for his mastery of the technical resources than for power of thematic invention or originality. In fact, his works exemplify all the characteristics of the ultramodern French style. His compositions include the symphonic poems, *The Death of Tintagiles, Avant que tu ne t'en ailles, Villanelle du Diable, Pagan Poem;* a suite for violin and orchestra; a *Fantastic Concerto* for cello and orchestra; a *Divertimento* for violin and orchestra; a string quartet; a string sextet; an octet for strings, two clarinets, and harp.

LOEFFLER, Friedrich (1852–1915). A German bacteriologist, born at Frankfort-on-the-Oder. He studied at the universities of Würzburg and Berlin, became assistant in the Imperial Health Office in 1879, and staff physician in Friedrich Wilhelm Institute in Berlin in 1884. In 1888 he was made professor at Greifswald. Loeffler did much to improve the technical methods of bacteriology, especially in the fields of preparation and staining. With Schütz he discovered the bacillus of glanders (1882), and he distinguished from true glanders a form prevalent among swine. In 1884 he described the "Klebs-Loeffler" bacillus of diphtheria, for which he devised a staining process and a special culture medium. With Frosch and Uhlenhutt he investigated the foot-and-mouth disease. Loeffler was a founder (1887) of the *Zentralblatt für Bakteriologie und Parasitik.* Besides contributions to this and other medical journals, and the treatment of malaria (1903) in Leyden and Klemperer's *Deutsche Klinik,* he published *Vorlesungen über die geschichtliche Entwicklung der Lehre von den Bakterien* (1887) and *Die Schutzimpfung gegen die Maul- und Klauenseuche* (1903).
